The work of these and other pioneers has led to a degree of certainty today with regard to a small percentage of tumors in and about the pituitary body which has lifted this group from its place among diagnostic problems. Any modern physician can make a diagnosis of acromegaly if a patient with the disease comes even within the periphery of his range of vision, and once the diagnosis is made, the panorama of this disfiguring ailment will float before his mind's eye. The problem before us in relation to acromegaly is limited, therefore, not to the diagnosis, but to the nature of the therapy to be applied. This, again, will depend upon the size and degree of hyperactivity of the eosinophilic adenoma of the pituitary body which is responsible for the symptoms. These, in turn, are determined by evidence resulting from studies in metabolism, x-rays of the skull, and ophthalmological examinations.

Experience with pituitary basophilism as contrasted with acromegaly, or "eosinophilism," to use a parallel term, is naturally much more limited, since the syndrome was described nearly fifty years later, and is, moreover, a much rarer condition. Furthermore, diagnostic pitfalls are present in the form of primary hyperadrenalism and perhaps certain primary gonadal and possible pineal disturbances. But given the classical picture as described by Cushing in 1932, and one may say with very little hesitation

are middle-aged or older, and who show no, or very few, signs of endocrine disturbance. X-rays of the skull, as a rule, show no changes in the sella turcica but may show a thickening of the bone of the tuberculum sellae and less often shadows of calcium salts deposited in the tumor itself.

When the signs are indefinite and encephalograms are made, the films usually show a perfectly normal ventricular system, but the cisterns appear definitely abnormal. The cisterna chiasmatis is frequently entirely obliterated. The cisterna lamina terminalis may be displaced dorsally and caudally, while the cisterna interpeduncularis may show a concave defect of its rostral margin due to the projection of the tumor mass into it.

Gliomas of the optic nerves may occur anywhere from the retina back to the optic tracts. The location which concerns us here is behind the globes, intracranially. These tumors are more common in childhood, but may affect mature adults. They usually begin with disturbances of visual acuity, and advance rapidly showing irregular defects in the visual fields, then blindness, first in one eye and then the other. The eyegrounds show primary optic atrophy. The functions of the pituitary gland are practically never disturbed. Signs of increased intracranial pressure may occur late in the disease.

Roentgenograms of the skull may show an undermining of the anterior clinoid processes giving the sella turcica a "J" shape. Whenever this lesion is suspected, roentgenograms of the optic foramina

should be obtained. These usually show an enlargement, erosion or deformity of the optic foramen on the side primarily affected.

While the classical case of glioma of the optic nerves or chiasm can be thus diagnosed without much difficulty, these cases are often also obscure and their diagnosis may be again aided by the use of encephalography. In the normal encephalogram, the optic nerves and chiasm are frequently seen as a band of increased density between the gas shadow of the cisterna chiasmatis rostrally and that of the cisterna interpeduncularis caudally. In the presence of a glioma of the optic nerves, the cisterna chiasmatis is usually obliterated and the shadow of the rostral border of the cisterna interpeduncularis shows a concave defect due to the projection backward of the tumor mass.

The other tumors in the region of the pituitary above enumerated are too rare to be diagnosed except by exclusion of the more common lesions and cannot be discussed here in detail.

Summary

Tumors in and around the pituitary gland, while presenting many symptoms in common, may be differentiated by their various manifestations depending upon their origin, character, size, position, and direction of growth. In spite of these characteristics, the diagnosis in any given case may be obscure, and under these circumstances encephalography may be brought in to clarify the situation.

NEUROLOGICAL INSTITUTE

Discussion

DR. E. H. CAMPBELL, *Albany*—At the present time the principal indications for surgical attack upon pituitary tumors are those of pressure upon or invasion of nearby structures. By far the most common lesion is the chromophobe adenoma and, as a general rule, the structure most often injured by its upward growth is the optic chiasm. However, as Dr. Davidoff has so well brought out, endocrine disturbances may long precede the first visual symptoms. For example, I recently removed such a chromophobe adenoma from a forty year old woman who had first noticed failing vision three or four years ago, but who without apparent reason, had had amenorrhea for the past seventeen years. For the

previous four or five years she had gained weight and it was found that her sugar tolerance was increased. It was presumed therefore, that these symptoms of endocrine disorder were attributable in some way to the presence of the adenoma, before it had reached sufficient size to impinge upon the optic chiasm.

Recently Costello is reported to have found small adenomas of various types in a surprisingly large percentage of hypophyses in several hundred routine autopsies. That such small adenomas may be responsible for most of the disorders of the endocrine glands is an inviting theory. However, it is necessary to preserve great caution in embracing such an idea too

ary optic atrophy, bitemporal hemianopia, and gradually diminishing visual acuity. At the same time, extension dorsally with compression of the hypothalamus may result in obesity and disturbances of water metabolism, with a resulting diabetes insipidus. At this stage, the gland has been almost completely thrown out of function. The patient takes on a "hypopituitary" appearance. In addition to obesity, he shows pallor, dry skin, fine sparse hair on the head, very little body hair, atrophy of the genitalia. The extremities are relatively small and the fingers tapering. He may be drowsy and mentally dull. The basal metabolism is usually below normal. Sugar tolerance is normal or increased. The temperature is subnormal, the blood pressure, low, the hemoglobin, diminished. Pressure symptoms on the chiasm have meanwhile advanced so that the patient may already be blind, or at least have markedly diminished visual acuity.

Experience has taught us, furthermore, that this tumor seldom occurs before puberty and is uncommon past middle life. Finally, roentgen examination of the skull shows enlargement of the sella turcica with atrophy of the clinoid processes and dorsum sellae and depression of the sellar floor. There are no accompanying signs of hyperpituitarism such as thickening of the skull, dilation of the paranasal sinuses or enlargement of the mandible as seen in acromegaly. The disturbances about the sella are also distinguishable from atrophy of this structure as a result of generalized increased intracranial pressure from tumor elsewhere in the brain, by the absence of pressure signs elsewhere in the skull.

The degree of extension of these tumors beyond the confines of the sella turcica may often be very difficult to judge on a clinical basis. In these cases, it is sometimes advisable to perform encephalography. The encephalograms seldom show enlargement or distortion of the ventricular system, but the basal cisterns, especially the cisterna interpeduncularis, may be seen to be displaced dorsally and the cisterna chiasmatis dorsally and usually also ventrally.

The *bucconeural pouch tumors* are congenital lesions which usually manifest their presence around the age of puberty, thus definitely appearing in an age group

that is younger than the one to which the pituitary adenomas belong. The symptoms are again of two kinds, those related to chiasmal pressure with resulting atrophy of the optic disks and bitemporal hemianopia, and those related to pressure upon the pituitary gland and the hypothalamic region of the brain. The latter usually take the form of skeletal retardation, sexual infantilism, adiposity, diminished basal metabolic rate, increased sugar tolerance, and disturbed water metabolism.

These tumors are most often partly or wholly cystic and rest above rather than within the sella turcica. This frequently results in a dorsal extension of the growth sufficient to obstruct the foramen of Monro with consequent hydrocephalus and clinical manifestations of increased intracranial pressure. In as high as seventy to eighty per cent of cases in addition to the characteristic clinical picture, the plain roentgenograms of the skull present a typical shadow above the sella turcica which is cast by calcium salts deposited in the cyst wall.

In spite of the numerous signs by which this disease may be recognized, an occasional case is encountered in which the diagnosis is in doubt. Here, again, pneumoencephalography may have to be carried out. Where increased intracranial pressure exists the gas is injected directly into the ventricles. The resulting roentgenograms show symmetrically dilated lateral ventricles but no gas beyond the interventricular foramina, or if it does enter the third ventricle this cavity appears displaced dorsally by the tumor mass. In the absence of increased intracranial pressure if the gas is injected by the lumbar route the chiasmal and interpeduncular cisterns are obliterated and even the cisterna pontis may be defective in its dorsal portion.

Suprasellar meningioma is a term applied by Dr. Cushing to tumors arising from the dura overlying the tuberculum sellae and extending dorsally and caudally to compromise the optic chiasm and nerves. Because of the latter, it also produces primary optic atrophy and bitemporal hemianopia and needs to be differentiated from the other tumors in this region. The suprasellar meningioma characteristically occurs in women who

CANCER OF THE ESOPHAGUS

WILLIAM L. WATSON, M.D., F.A.C.S., *New York City*
Assistant Attending Surgeon, Memorial Hospital

Since our first report which was based on a series of 509 cases of cancer of the esophagus, we have had an additional experience in the care of 157 patients afflicted with this disease. In this latter group, more modern principles of treatment by means of physical agents were employed and a study of this group of cases seems to invite analysis of our impressions.

35 per cent of all cancer deaths in New York City are caused by cancer of the esophagus and this means that 300 cases of cancer of the esophagus die yearly in New York City. Other cities, where statistics are available, report even higher percentages, figures up to ten per cent have been quoted from several European centers.

The etiology of this disease still remains obscure, but we have the definite impression that poor teeth, intraoral sepsis, thermal irritation, repeated trauma, congenital defects, diaphragmatic hernias, diverticula, and scars of old lye burns play a role as predisposing causes of cancer of the esophagus. We have had one young man, thirty years of age, who developed squamous carcinoma of the upper esophagus in an area of heavy scar tissue resulting from a severe lye burn accidentally contracted twenty-seven years previously. That poor teeth, intraoral sepsis, etc. exert an influence in the causation of intraoral cancer has been generally accepted, and it seems not without significance that in the present series of cases eleven patients had double cancer, and of these we wish to report that in eight cases the other primary cancer was located in the oral cavity and in each of these eight, one or more of the above predisposing factors was demonstrated. It does not seem unreasonable to consider that the same predisposing factors were responsible for the commencement of cancer in both locations.

The diagnosis in most cases is quite

readily established by a careful history, physical examination, and satisfactory radiograph of the esophagus after barium swallowing. I do not feel safe, however, in relying entirely on a roentgen examination. Cancer of the esophagus is simulated by a number of benign conditions and an early lesion of the upper esophagus may readily be missed even after examination of a good film. Forty-four patients have been admitted to the Memorial Hospital with a diagnosis of cancer of the esophagus in whom we have been able to demonstrate the presence of a benign condition causing symptoms and radiographic findings indicative of cancer. Esophagoscopy is therefore necessary in all uncomplicated cases, as is also fluoroscopy with the patient in two positions.

Biopsy specimens of esophageal growths removed during esophagoscopy are examined by Drs. Ewing or Stewart and we learn in reviewing this histological material that ninety per cent of our cases are diagnosed as squamous carcinoma and two-thirds of these are reported as grade 2 and of these sixty-six per cent are found to be radioresistant. In the series of cases under discussion, there were also thirteen adenocarcinomas, one transitional cell carcinoma, and one spindle cell carcinoma. Only sixteen of the squamous carcinomas fell into the grade 3 group.

Cancer of the esophagus very often remains to the end a localized disease and death results from perforation of the growth into a vital structure. At autopsy quite often no signs of secondary deposits are to be found. In our first series of cases there were twenty-seven autopsies and metastases were absent in thirteen cases (forty-eight per cent). In the present series of 157 cases there were twelve autopsies and secondary deposits were noted in six cases (fifty per cent). Metastases were demonstrated clinically in eighteen patients and two of these patients had bone metastases; one of these went on to a pathological

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

quickly. It is well to bear in mind in connection with the pituitary adenomas that, as in the case of similar lesions in the thyroid, they may not at all times be hyperactive. The pituitary hormones themselves are not known chemically and there is even considerable uncertainty about the existence of some of the many postulated substances. Until our knowledge of the physiology of the pituitary gland has advanced consider-

ably further, the majority of the surgical attacks upon the gland must be directed towards the relief of the symptoms of local pressure. The symptoms of endocrine disorder are of considerable help diagnostically. However, it is not always possible to predict what effect surgery or the various available extracts will have upon the deranged functions of the ductless glands.

COD LIVER OIL AS A WOUND DRESSING

Cod liver oil within the past several years has become popular in medical circles as a healing agent for wounds, burns and similar traumatic conditions. Medical scientists from many parts of the world have conducted extensive studies on the subject and have announced excellent results, says an article in the *Druggists Circular* by Raphael M. Nacca.

More than two years ago Dr W. Lohr, a German physician, found that the use of cod liver oil was very effective in cleansing infection from burn wounds. The doctor said that not only was the infection controlled, but the growth of epithelium was stimulated, especially in the case of burns covering large areas of the body, such as burns of the back.

In describing the action of cod liver oil in the healing of wounds and burns, the doctor says that it permeates through the tissues, bringing about the liquefaction and removal of dead tissue and stimulating the growth of new tissue.

Dr H. Lucke, another German medical scientist, also experimented with the cod liver oil salve. He found it very efficacious in treating carbuncles, boils, abscesses and infected wounds, he also healed a patient suffering from an old fistula and another with a trophic ulcer through its use. This doctor recommended that the salve-covered dressings be changed every two days, especially in the cases of suppurative wounds.

The popularity of cod liver oil as a healing agent soon spread to other countries. Dr J. P. Steele, of England, used it with success in treating burns, ulcers and wounds, however, his method of application differs somewhat from that of the German doctors. Lint thoroughly soaked in cod liver oil is applied to the burned area and then covered with a bandage, this dressing is soaked again with oil the following day, and the lint is removed after a period of two days. Dr Steele says that the cod liver oil not only gave relief immediately upon application but also brought about a rapid healing with the growth of healthy new

tissue in cases which had not responded to the usual methods of treatment. This English medical scientist also used cod liver oil, by the above method, in successfully treating fistula, ulcers and deep skin abrasions, however, he first removed any pus or gangrenous tissue which was present in these conditions before applying the cod liver oil dressing.

Russian medical scientists were the next to study the healing action of cod liver oil. Drs V. K. Tumansky and I. A. Yatskevich devoted much of their attention to the bactericidal properties of the oil, after demonstrating through laboratory experiments the bactericidal power of cod liver oil. Drs Tumansky and Yatskevich applied their knowledge clinically and healed the infected wounds of fifty-three patients by means of cod liver oil dressings.

Other Russian physicians painted the clinical picture in even more detail. Dr V. I. Iost and Dr I. G. Kochergin treated more than two hundred and fifty patients with cod liver oil. Among these cases were one hundred and fifty fresh superficial skin wounds, forty suppurating wounds, twenty-eight chronic ulcers, twenty-five burns and frostbites, nineteen severe wounds of the body extremities, and ten open stumps.

The results of the clinical studies of these doctors showed that the cod liver oil treatment was of value in healing all of these various conditions. The healing action of the cod liver oil is due, the Russian physicians believe, as did the German physician, Dr Lohr, to the vitamins A and D in the oil, the vitamin D being the agent which stimulates the growth of new tissue.

Cod liver oil in the form of a salve or paste was considered the best method of application by the Russian medical scientists, for they say a paste keeps the oil in close contact with all parts of the injured area. The paste which they used in the clinical investigations consisted of equal parts of cod liver oil and sterile petrolatum with the addition of about five percent of Japan wax and nearly one percent of a vitamin preparation to give additional vitamin strength.

only to preserve that portion of skin from possible damage due to cross-firing

The patient receives his treatment daily in rotation to these four ports. The average daily exposure is 300 r and the total for each port ranges from 2,100 r to 3,300 r depending on the patient's tolerance and the skin reaction. Other factors are 200 K V, 30 Ma, 70 cm T-S distance, $\frac{1}{2}$ mm cu filtration, and treatment time of eleven minutes. The data on the cases treated by the 700 K V machine is incomplete due to mechanical difficulties with this particular machine which caused many interruptions and numerous cancellations during the outlined course of treatment.

In the second group of cases, treatment was entirely by gastrostomy and intra-esophageal irradiation with a special thirty mg radium element tandem. This applicator, with a total of filtration equivalent to only two mm of brass, was found to have a most beneficial effect in lessening tumor infection, healing ulceration, and widening the lumen of the esophagus at the tumor site, but had apparently little effect on the main tumor mass. Higher filtration up to two mm of platinum has been recommended by J. Gusez of France who reports good results with his applicator so filtered. Our tandem was inserted under esophagoscopic control and fixed in place for a period of twenty-four hours giving 720 mg hours. It was then removed and again inserted the following day for another 720 mg hours. A total dose of 4,320 mg hours was the objective.

In the third group were cases which came to us with complete esophageal obstruction and gastrostomy was done to prevent death by starvation. This was followed by enough general improvement in the patient's condition to warrant giving a course of external radiation. Due to the combination of gastrostomy and x-ray treatment the lumen of the esophagus again became patent and the radium element tandem could be inserted without undue trauma. Each patient in this group was a poor risk on admission.

In the fourth group, we have a small number of cancers which occurred in that portion of the esophagus from the piriform sinuses down to the level of the arch of the aorta. These cases theoretically are operable, but, in four such cases exposed through a cervical incision in the past year, all were found to be inoperable. In two cases widespread infiltration and fixation were

present, and, in the other two, extensive cervical metastases were present. After surgical exposure three of these cases had gold-filtered radon seeds inserted into and around about the tumor. This group offers our greatest opportunity to treat the cancer with an adequate, concentrated, and localized dose of interstitial radium. The gold seeds can be placed into the tumor itself without going through an infected ulcerated surface as is necessary if the seeds were to be inserted through the esophagoscope. As in the treatment of metastatic neck nodes, we find that visualization of the tumor mass by surgical exposure allows us to accurately determine its size and estimate the dose of radon necessary to sterilize that mass of grade 2 squamous cancer.

The thoracic portion of the esophagus is surrounded by vital structures and a large quantity of blood passing through the aorta, the heart, and lungs is necessarily exposed to the effect of the x-rays during the treatment period. We were at first a little apprehensive as to what possible untoward constitutional effects we might produce in this way by our treatment. We have had blood counts taken before and after heavy external radiation to the chest and found practically no change in the red blood count and only a slight drop in the white blood count. Lung fibrosis following treatment was not noted in any of our cases.

Summary

Treatment of esophageal cancer by divided doses of x-ray is usually followed by symptomatic and radiographic evidence of improvement and occasionally apparent complete regression of tumor occurs. Of sixty-eight cases so treated, thirty-three are alive, eight for one year or more and two for two years. In the previous series of cases the average length of life for all cases was 4.8 months.

If a radium tandem is to be used, heavy filtration of the capsules is recommended.

Surgical exposure of esophageal cancer and implantation of gold-filtered radon seeds into the tumor and tumor bed is suggested as a method of treatment offering several logical advantages.

Discussion

DR. DAVID E. EHRLICH, *New York City*
—Dr. Watson has given us the latest from Memorial Hospital. I will add some data

from the New York City Cancer Institute Department of Hospitals, where we receive the more advanced and terminal cases.

fracture of the right humerus, and the other perforated the outer table of the skull resulting in a soft part tumor which was aspirated and metastatic squamous carcinoma demonstrated. Autopsy confirmed the clinical findings. We believe the unusual and more frequent metastases noted in this second series may be due to closer observation of our patients or to the fact that our patients are living long enough to develop demonstrable metastases. Two cases treated heavily by the protracted method of x-radiation died as a result of perforation of the esophagus followed by suppurative mediastinitis. At autopsy, in these two cases, no residual cancer was found and metastases were absent. These early cases demonstrated to us the ability of heavy external radiation to completely destroy esophageal cancer. It remains for us to find a way to accomplish this without causing esophageal perforation.

Gastrostomy is necessary when one proposes to use a removable intraesophageal radium tandem, and many advanced and emaciated patients must be given the advantage of a physical building up by gastrostomy feedings so as to withstand a protracted course of external irradiation. Due to lack of bed space, we have been unable to admit a number of our patients for gastrostomy and have been forced to treat them by external irradiation, and we have been gratified to note that eight of these patients have survived a year or more without gastrostomy. One patient managed nicely for two years after treatment but then had a recurrence, lost weight, and a gastrostomy had to be done. Since then he has gained 26 pounds in weight (3 months). This patient followed his usual work for two years after treatment.

The aim of treatment, until a method of cure is devised, should be to see to it that each patient has as full a measure of comfortable life as it is possible for us to give him. With prolongation of life as our objective, we cannot recommend radical surgery because of the prohibitive mortality rate. We have employed irradiation in a series of consecutive cases as they came to us. No patient was refused treatment no matter how hopelessly advanced or critically ill he may have been. Some patients died before irradiation

could be given, some during the course of treatment, and others shortly after its completion. These patients died of their disease, and I have no way of knowing whether irradiation hastened their end or not. Such cases would not at the present time be selected for aggressive irradiation therapy.

Treatment has been carried out along four different lines and this permits us to divide the series into four groups for purpose of discussion. The first and most important group includes those cases treated by the protracted or fractionated dosage method using either the 200 or 700 K V machines. The second group was treated by gastrostomy and a special radium element tandem for intraesophageal irradiation. The third group consisted of cases treated first by gastrostomy and then by heavy external radiation followed by divided doses with the radium element tandem. The fourth group is composed of a small number of cases of cancer of the upper esophagus treated by surgical exposure of the lesion and insertion of gold-filtered radon seeds directly into and about the growth.

In the first group, those cases treated by x-radiation, proper outlining of the treatment portals is of the greatest importance. In order to accurately cross-fire the beam of x-ray in the thoracic cavity at the level of the cancer, one must first map out the portals on the skin of the chest anteriorly and posteriorly under fluoroscopic control with the patient in the position in which he is to receive his treatment. The upper and lower limits of the disease are marked with lead strips both anteriorly and posteriorly. The posterior ports will often be found several centimeters higher than those on the anterior chest wall. The angle at which the treatment beam is to be directed will depend on the size of the patient's chest and the level of the lesion, but a practical estimation of this angle may be obtained while fluoroscopically marking out the treatment ports. With improved fluoroscopy and better roentgenographs we are often surprised to note how large the soft part tumors are which surround the areas of obstruction and ulceration noted in the lumen of the esophagus on fluoroscopy and esophagoscopy. For this reason, we seldom use skin portals smaller than fourteen by seven cm. Four of these portals are used—two anterior and two posterior—leaving a free zone four cm wide in the midline anteriorly and posteri-

only to preserve that portion of skin from possible damage due to cross-firing

somewhat radio-lucent, suggesting the possibility of pneumo-pericardium"

On July 19, the patient died.

The autopsy examination (Fig 3) revealed an ulcerated lesion measuring about six cm in length at the middle third of the esophagus. In this region the posterior wall of the esophagus was made up only of necrotic tissue, and in the same area there were three fistulous openings (1) The first was two cm. in diameter, leading to the parenchyma of the mid-third of the left lung, giving rise to necrosis, (2) another was one cm. in diameter and leading to the right main bronchus, two cm. from the bifurcation and (3) another led through this portal, 1.5 cm. in diameter, just below the right branch of the pulmonary artery, and communicated directly with the pericardium. The pericardial sac was nearly obliterated. The visceral pericardium was markedly thickened by fibropurulent depositions. In the lower third of the esophagus, just beneath the mucosal coat, there was a whitish, elevated area, measuring about three by six cm in diameter, at

Fig 3

the cardiac end of the stomach another similar but larger lesion, elevated but not ulcerated, was situated. These were interpreted as metastatic depositions through the submucous lymphatics

Five days after death microscopic sections taken from the middle-third and the lower portion of the esophagus showed squamous cell epithelioma with infection.

Comment In this case the antemortem diagnosis of pneumopericardium was confirmed. In the literature only seven cases have been reported of pericarditis with carcinoma of esophagus and only one of pneumopericarditis reported by J W Begbie (*Monthly J M Sc London and Edinb*, 10 165, 1850). The paucity of the literature justifies this case report.

I wish to voice my thanks to Dr Watson for bringing before us the study of carcinoma of the esophagus which according to our New York City Cancer Institute statistics is twice as common as carcinoma of the lung, and fully as fatal

REMOVE THE LABEL

If you feel obligated to give to your patient a sample bottle of medicine do not be too tired to remove the label

The encouragement of self-medication which the doctor sponsors when he hands out samples of medicine, or directs the patients to procure certain publicized preparations, is a direct means of creating a customer demand for pharmaceutical manufacturers. In many instances the physician or dentist is the best avenue for these manu-

facturers to educate the public to the value of their preparations

The druggists frequently have customers who bring in a sample bottle of medicine and state that sometime ago Dr _____ gave this medicine to their neighbor, and they think that it might be helpful to them in their present illness, and if so, it would save them the expense of calling the doctor

—Kansas Medical Journal

Since 1923 we have had 250 cases diagnosed clinically cancer of the esophagus out of a total of 14,000 admissions (18%). In two cases the admission diagnosis from the other institutions was changed from cancer to syphilis of the esophagus and about two years follow-up on these two cases with the positive Wassermann sustained our impression of absence of malignancy. One case was discharged after a piece of nut shell was removed from the middle third of the esophagus.

The accompanying table was taken from a paper on "Treatment of Cancer Patients Study of End Results in 351 Autopsied Cases" by Dr Ira I. Kaplan, the Director of our Cancer Institute and published in the *NEW YORK STATE JOURNAL OF MEDICINE*, March 1, 1936. This table gives a five year summary of esophagus-autopsied cases at our Cancer Institute, being therefore a cross section of our series.

Before closing I wish to cite another case which came in subsequent to this tabulation. I am reporting in collaboration with Dr Paul T. Meyers, the following case of "Carcinoma of the Esophagus With Perforation into Lung and Pericardium and Consequent Pneumopericardium."

J. L., a forty-three year old colored male, was admitted to the Cancer Hospital on July 10, 1935. He had previously been in another hospital where he had been admitted on March 14, 1935, complaining of dysphagia for one and one-half weeks. He was unable to swallow solid foods unless finely chopped and washed down with water. There was no hematemesis.

Fig 1

Twenty pounds of weight had been lost in the preceding four weeks. Physical examination revealed an aortic diastolic murmur transmitted to the axilla. Wassermann and Kahn tests were negative. The chest x-ray was negative except for an atheromatous plaque in the aortic arch. Fluoroscopic and radiographic examination of the esophagus revealed a definite organic stenosis at its mid-third. An esophagoscopic biopsy showed no evidence of malignancy, leukoplakia being considered as a possibility.

The dysphagia increased, the patient was unable to swallow even fluids, and attempts to pass the smallest sized tubes were unsuccessful, on May 14, a tube gastrostomy (Janeway technic) was performed.

When the patient was admitted to the Cancer Institute, he stated that four days previously he had been attacked with a severe, "ripping" pain in the upper sternum, which moved later to the lower sternum. This persisted at the time of admission and was severe enough to confine him to bed. There were no chills, fever or excessive perspiration. Dyspnea was present in marked degree which was associated with considerable pain.

Because of his grave condition the patient was radiographed in bed with a portable x-ray machine. (Fig 1) The roentgenograms revealed no pulmonary consolidation, and the barium in the esophagus outlined an organic narrowing extending upward from the level of the ninth dorsal vertebra. At this point there was a distinct branching of the barium column into the right hilum. The Roentgen diagnosis was a carcinoma of the esophagus, with perforation into one of the right bronchi (Fig 2). A re-examination of the chest five days later (July 17) revealed an "irregular emphysematous pneumonitis in the lower lobes, superiorly. The right cardiac margin appears

TABLE

Color	White 16	Colored 4
Marital state	Married 13	Single 6, Not stated 1
Birthplace	U S A 7,	Foreign 13
Age	Oldest 72,	Youngest 44

Perforation in trachea	3	Lung perforation 2

with the resultant formation of ammonium carbonate. This then combines with the magnesium salts and phosphates, forming magnesium phosphate and, as the urine is rendered alkaline in reaction, precipitation of the insoluble earthy phosphates also occurs.

While reports in the literature indicate that urea splitting infections do not occur frequently, aside from those belonging to the *Proteus* group, Brown and Earlam⁵ have demonstrated that eighteen per cent of the bacilli which infect the urinary tract have the power of splitting urea, and many staphylococcus act in a similar manner. Forty per cent of the strains of *Staphylococcus albus* which Brown and Earlam examined had the urea splitting property. Hellström⁶ also emphasized the importance of these organisms.

In my series of cases, infection which has been associated with the *Proteus* group has been extremely resistant to treatment and the acid-ash diet, the ketogenic diet, and the oral administration of acidifying agents have failed to eradicate the infection in the majority of patients. Thus, in instances where a coexisting *Proteus* infection is present, we have secured the best results by suturing a small catheter with triple O plain catgut into the pelvis of the kidney or by introducing a catheter through the renal cortex into the pelvis of the kidney through a small trocar. Following this, the kidney is lavaged at frequent intervals with a one per cent solution of phosphoric acid alternating with a one per cent solution of mercurochrome. This is done for a period of from ten days to two weeks.

In other types of infection, acidifying agents such as sodium acid phosphate, ammonium chloride, nitrohydrochloric acid, and urotropin frequently suffice to eliminate the infection. If an unfavorable response occurs following the use of such medication, the ketogenic diet is employed. This is gradually modified and the high vitamin A acid-ash diet is prescribed, and due to the fact that acetone, diacetic, and beta-oxybutyric acid are not present in the urine, there is little danger of acidosis when a patient is following the high vitamin A acid-ash diet. If possible, the renal infection should be eradicated before the patient is discharged from the hospital. In many instances, the use of the high vitamin A acid-ash diet is suffi-

cient to eliminate the infection as the pH of the urine is maintained between 5 and 5.2 for a considerable period of time.

Stasis. Urosthesis in certain instances seems definitely to be associated with the formation of calculi and frequently it is conducive to shifting the pH of the urine to the alkaline side. The observations of Hunner⁷ emphasize the importance of ureteral stricture as an etiological factor in the formation of recurrent calculi.

Stasis may be demonstrated by an intravenous urogram which is made prior to operation and following the removal of the calculus before the patient leaves the hospital. Such a study is of value also in localizing the lesion which is producing the obstruction in the ureter or at the ureteropelvic junction. I believe this procedure is an essential step in the pre-operative and postoperative routine.

If a stricture of the ureter is present, it must be corrected by ureteral dilations or other procedures.

Correction of Vitamin A deficiency

Vitamin A is prescribed for two reasons: (1) To overcome vitamin A deficiency if present and (2) because of its specific effect on the epithelial structures.

It is frequently very difficult to determine or elicit evidence of vitamin A deficiency by questioning the patient concerning his diet. Various discussions have arisen in the past regarding the incidence of vitamin A deficiency in this country, but evidence is being accumulated which indicates that mild degrees of deficiency occur more frequently than has heretofore been recognized. Although xerophthalmia and night blindness occur relatively infrequently, lesser degrees of deficiency, which cannot be detected by the usual clinical examination, may be present for long periods of time. This is indicated by the recent report of Jeans⁸ who used the photometer test for dark adaptation in determining vitamin A deficiency in children. He observed 100 children of the middle and low economic levels of a rural community and in twenty-six per cent he secured a positive test for vitamin A deficiency, of 102 children of all economic levels in a village, fifty-three per cent presented definite evidence of vitamin A deficiency. Of seventy children of the upper economic level in a city, fifty-six per cent had positive

FACTORS WHICH INFLUENCE THE FORMATION OF URINARY CALCULI

Clinical Application to the Prevention of Recurrent Renal Calculi

C C HIGGINS, M D, *Cleveland, O*

The recurrent formation of renal calculi following conservative operations for renal lithiasis occurs with sufficient frequency to warrant consideration of the basic factors involved in this complication. Although numerous publications dealing with the etiological factors associated with the formation of calculi, operative technic, and differential diagnosis may be found in the literature, a paucity of articles concerning the prevention of recurrent lithiasis is available.

Such procedures as cholecystectomy, appendectomy or resection of the rectum for carcinoma are effective inasmuch as they remove the organ and the underlying pathology, but the surgical removal of a calculus from the kidney treats only an "effect" and in no conceivable way corrects the cause or alters the factors responsible for the formation of the stones. It is necessary, therefore, to consider the operative procedure *per se* as only one phase in the correct management of renal lithiasis.

Recurrent renal calculi may be classified in the following manner:

1 True recurrence, or the formation of a calculus after complete removal of the original stone.

2 False recurrence, or the persistence of stones or fragments of calculi which were overlooked at the time of operation.

Unless a roentgenogram is secured before the patient leaves the hospital, it is impossible to state with any degree of certainty whether a true or a false recurrence has occurred. It is likewise true that small fragments may not be discovered during the operation, and they may not be revealed even by roentgenographic examination. Since these fragments may act as nuclei for the further formation of calculi, every precaution should be taken to avoid overlooking them during the operative procedure. In doubtful cases, we have found it helpful to use the method described by Quinby,¹ who

recommends that a small film be placed behind the delivered kidney in order to make a roentgenographic study. Braasch and Carman² have described a technic for fluoroscopic examination which is a valuable aid. Lower³ has devised an instrument by means of which the calyces and pelvis of the kidney may be lavaged thoroughly with saline solution after which suction is applied, thereby removing small stones, fragments of calculi, and sand which otherwise would be retained.

Various etiological factors, such as infection, vitamin A deficiency, hyperparathyroidism, cystinuria, phosphaturia, and oxaluria may be instrumental in the recurrent formation of urinary calculi.

Infection may be divided into two groups: (1) focal infection and (2) infection confined to the genitourinary tract.

Focal Infection

In 1921, Rosenow and Meisser⁴ demonstrated a specificity of streptococci in the formation of urinary calculi. They inoculated the pulps of the teeth of six dogs with streptococci isolated from the urine of patients who had renal lithiasis and following this, calculi developed in the dogs and streptococci were again isolated from the urine. In view of these observations we believe that all foci of infection should be removed including infection of the teeth, tonsils, prostate, cervix, and the bowel.

Infection confined to the Genito-Urinary tract

Infection of the kidneys. The nature of infection in the presence of recurrent renal calculi varies considerably, and it is essential to determine whether such infection is caused by (1) urea splitting organisms or (2) by non-urea splitting organisms. In the presence of an urea splitting infection in the kidney, urea is split into ammonia and carbon dioxide.

with the resultant formation of ammonium carbonate. This then combines with the magnesium salts and phosphates, forming magnesium phosphate and, as the urine is rendered alkaline in reaction, precipitation of the insoluble earthy phosphates also occurs.

While reports in the literature indicate that urea splitting infections do not occur frequently, aside from those belonging to the *Proteus* group, Brown and Earlam⁶ have demonstrated that eighteen per cent of the bacilli which infect the urinary tract have the power of splitting urea, and many staphylococcus act in a similar manner. Forty per cent of the strains of *Staphylococcus albus* which Brown and Earlam examined had the urea splitting property. Hellström⁸ also emphasized the importance of these organisms.

In my series of cases, infection which has been associated with the *Proteus* group has been extremely resistant to treatment and the acid-ash diet, the ketogenic diet, and the oral administration of acidifying agents have failed to eradicate the infection in the majority of patients. Thus, in instances where a coexisting *Proteus* infection is present, we have secured the best results by suturing a small catheter with triple O plain catgut into the pelvis of the kidney or by introducing a catheter through the renal cortex into the pelvis of the kidney through a small trocar. Following this, the kidney is lavaged at frequent intervals with a one per cent solution of phosphoric acid alternating with a one per cent solution of mercurochrome. This is done for a period of from ten days to two weeks.

In other types of infection, acidifying agents such as sodium acid phosphate, ammonium chloride, nitrohydrochloric acid, and urotropin frequently suffice to eliminate the infection. If an unfavorable response occurs following the use of such medication, the ketogenic diet is employed. This is gradually modified and the high vitamin A acid-ash diet is prescribed, and due to the fact that acetone, diacetic, and beta-oxybutyric acid are not present in the urine, there is little danger of acidosis when a patient is following the high vitamin A acid-ash diet. If possible, the renal infection should be eradicated before the patient is discharged from the hospital. In many instances, the use of the high vitamin A acid-ash diet is suffi-

cient to eliminate the infection as the pH of the urine is maintained between 5 and 5.2 for a considerable period of time.

Stasis. Urosthesis in certain instances seems definitely to be associated with the formation of calculi and frequently it is conducive to shifting the pH of the urine to the alkaline side. The observations of Hunner⁷ emphasize the importance of ureteral stricture as an etiological factor in the formation of recurrent calculi.

Stasis may be demonstrated by an intravenous urogram which is made prior to operation and following the removal of the calculus before the patient leaves the hospital. Such a study is of value also in localizing the lesion which is producing the obstruction in the ureter or at the ureteropelvic junction. I believe this procedure is an essential step in the preoperative and postoperative routine.

If a stricture of the ureter is present, it must be corrected by ureteral dilations or other procedures.

Correction of Vitamin A deficiency

Vitamin A is prescribed for two reasons: (1) To overcome vitamin A deficiency if present and (2) because of its specific effect on the epithelial structures.

It is frequently very difficult to determine or elicit evidence of vitamin A deficiency by questioning the patient concerning his diet. Various discussions have arisen in the past regarding the incidence of vitamin A deficiency in this country, but evidence is being accumulated which indicates that mild degrees of deficiency occur more frequently than has heretofore been recognized. Although xerophthalmia and night blindness occur relatively infrequently, lesser degrees of deficiency, which cannot be detected by the usual clinical examination, may be present for long periods of time. This is indicated by the recent report of Jeans⁹ who used the photometer test for dark adaptation in determining vitamin A deficiency in children. He observed 100 children of the middle and low economic levels of a rural community and in twenty-six per cent he secured a positive test for vitamin A deficiency, of 102 children of all economic levels in a village, fifty-three per cent presented definite evidence of vitamin A deficiency. Of seventy children of the upper economic level in a city, fifty-six per cent had positive

tests Of seventy children of middle economic level in a city, sixty-three per cent showed evidence of vitamin A deficiency and of sixty-two children of a low economic level in the city, seventy-nine per cent had a positive test for vitamin A deficiency Of seventy-eight village and city children who were deficient in vitamin A and who continued to remain under observation, all but three developed normal adaptation to darkness after a period of vitamin A therapy

In our recent series of forty-three patients with renal lithiasis, positive evidence of vitamin A deficiency was shown by the Jean's Test in fifty-eight per cent in spite of the fact that many seemed to have well-balanced diets It is an interesting fact that in the past year and a half, practically the same percentage of vesical and renal calculi was produced experimentally by the use of a new diet deficient in vitamin A This diet was used by the S M A Corporation in their work with carotene-in-oil and it has been approved by the Council of Pharmacology and Chemistry of the American Medical Association After maintaining the rats on the deficiency diet from 250 to 275 days, vesical calculi developed in from eighty-six to ninety-two per cent and renal calculi in from thirty-four to forty-two per cent of the animals During this period, it was noted that stratification of the epithelium of the bladder, ureters, and kidney pelves and karatinization occurred and, in many instances, this was followed by desquamation of the epithelium and even ulceration When vitamin A was restored to the diet, the epithelium returned to normal

In a few clinical cases, I have removed a small piece of the kidney pelvis adjacent to the calculus at the time of operation Examination of this tissue has shown complete loss of epithelium which, in some instances, had resulted in an acute inflammatory lesion with ulceration Sometimes small accumulations of sand may be quite adherent at the site of the lesion and this may act as a nucleus for further enlargement of a calculus by deposition of salts which are precipitated in the urine Finally, this accumulation of sand may be expelled spontaneously down the ureter or drop into the dependent lower calyx of the kidney, which is the usual site for the formation of calculi Here this

nucleus gradually enlarges after further deposition of phosphates and carbonates Therefore, due to its specific effect on the epithelial structures and in order to correct vitamin A deficiency, it is a part of the dietary regimen

Hyperparathyroidism

The observations of Barney and Mintz,⁹ Chute,¹⁰ Albright and Bloomberg,¹¹ and others have focused our attention on the relation between hyperparathyroidism and renal lithiasis

In our series of 210 cases in which complete blood studies have been made, there has been one case of hyperparathyroidism This patient presented some of the most marked evidences of vitamin A deficiency we have seen She herself had noticed the presence of night blindness and a positive Jean's test was present The night blindness disappeared following the administration of carotene-in-oil, and the diagnosis of hyperparathyroidism was verified by the removal of an adenoma from the parathyroid gland

In all cases of renal lithiasis, an examination of the blood should be made to determine whether a high level of serum calcium and a low level of serum phosphorous are present, such as are seen in hyperparathyroidism If the serum calcium level is elevated and the serum phosphorous level lowered, it is advisable to make roentgenographic studies and to study the elimination of calcium and phosphorous in the urine.

Cystinuria

This metabolic disease occurs rather infrequently Seegar and Kearns¹² collected a series of 181 cases of cystinuria and found 124 instances of renal lithiasis Cystinuria is believed to be due to an error in metabolism and may be associated with a disturbance of the intermediate protein metabolism Heredity seems to be an important factor and several authors have reported the occurrence of cystine calculi in more than one member of a family

Phosphaturia

Temporary phosphaturia may be caused by various metabolic disturbances, or temporary alkalinity of the urine may be due to eating an excessive amount of cit-

rus fruits such as oranges or lemons or taking an excess of alkaline ash in the diet.

Permanent noninfected phosphaturia may be associated with alteration in function of the large bowel while permanent infected phosphaturia is due to the deposition of phosphates by urea splitting organisms, and this frequently is associated with the formation of recurrent calculi.

Oxaluria Neville¹³ has stated that oxaluria may occur in patients who are subsisting on a diet deficient in vitamin B. Thus vitamin, therefore, should be added to the diet. If an elevation in the blood uric acid is present, then the purins must be restricted.

Clinical application

In view of our experimental and clinical observations during the past four years, the following routine is used postoperatively in all cases of renal lithiasis.

- 1 Elimination of stasis
- 2 Eradication of infection
 - a. Focal
 - b. Infection of the genitourinary system
- 3 Correction of metabolic disturbances
- 4 Treatment of hyperparathyroidism if present.
- 5 Correction of vitamin A deficiency
- 6 Correction of vitamin B deficiency
- 7 Dietary regimen

In this discussion, only the postoperative dietary management will be considered.

Dietary regimen In our early cases, we believed a knowledge of the pH of the urine in the bladder would provide sufficient information to determine whether the high vitamin A acid- or alkaline-ash diet should be prescribed. However, occasional exceptions were observed, and it was found that it is important to determine the pH of the urine from each kidney. This is especially true when a urea splitting organism is found in the urine obtained from the kidney containing the stone, while a similar infection is not present in the other kidney. In seventeen patients in our series, it was found that a unilateral urea splitting infection was present which would account for the difference in the pH of the urine from the kidney harboring the calculus. However, in eleven cases, no infection was present in either kidney, but there was marked

impairment of renal function and stasis in the kidney containing the calculus. Herrold, in a recent Urological Club letter reported cases in which this had occurred and Randall¹⁴ has mentioned it also. Therefore, to ascertain correctly which diet should be prescribed, the pH of the urine from the kidney which contains the calculus must be known. Likewise, if calculi are removed surgically or passed spontaneously, they should be analyzed to determine the chemical constituents, thereby ascertaining whether the salts present are those which are precipitated in urine with an alkaline or an acid reaction. If the reaction of the urine from the kidney containing the calculus is alkaline or if the calculus is found to be composed of phosphates, carbonates or oxalates, the high vitamin A acid-ash diet should be prescribed. If the reaction of the urine, however, is acid, or if the stones are found to be composed of uric acid or of cystine, the high vitamin A alkaline-ash diet should be prescribed, the fundamental purpose of the diet being to adjust the pH of the urine to a point where the salts are held in complete solution so that precipitation cannot occur. By reducing the pH of the urine to 5 or 5.2, the phosphates and carbonates of calcium and magnesium which are the chemical constituents of most recurrent renal calculi, are held in complete solution and precipitation does not occur. Similarly, by the use of the alkaline-ash diet, cystine and uric acid salts are held in complete solution. Frequent examinations of the urine should be made to ascertain that the various salts are not being precipitated. If the pH of the urine is reduced too strongly to the acid side, precipitation of uric acid salts may occur. Each patient must be individualized and the pH of the urine must be adjusted to the point at which the salts essential for the formation of a calculus are not precipitated.

In the past three months, my laboratory assistant, Mr. Kovach, and I have made studies to determine the range of precipitation of the various urinary salts according to pH readings. We have attempted to determine the pH of the urine at which precipitation of phosphates, carbonates, oxalates, urates, and cystine first occurs. These results will appear in the literature shortly.

As stated previously, the majority of

recurrent calculi are composed of magnesium, calcium phosphates, and carbonates, consequently, as a general rule, the high vitamin A acid-ash diet is prescribed. The basic diet contains an excess of acid-ash of 17.3 and the constituents of the diet are varied daily until the pH of the urine is reduced to 5 or 5.2 and maintained at this point, thus the patient at the time of discharge, may have an excess of from twenty-five to thirty c.c. of acid-ash in the diet. In some instances, acidifying agents such as nitrohydrochloric acid, ammonium chloride or sodium acid phosphate are administered also to maintain the correct pH of the urine.

High vitamin Acid-ash diet

The purpose of this diet is to furnish an adequate high vitamin diet in which the total acid-ash exceeds the total basic-ash. To accomplish this, it is absolutely necessary that no salt be used for seasoning foods, either in cooking or at the table.

The following foods, in the amounts designated, must be included in the diet daily.

A ACID-ASH FOODS (Minimum amounts)

I CEREAL—Any one of the following measured servings (2 c.c. excess acid-ash)

Cornflakes	1 cup heaping
Cornmeal (cooked)	$\frac{2}{3}$ cup
Farina (cooked)	$\frac{2}{3}$ cup
Oatmeal (cooked)	$\frac{1}{2}$ cup
Puffed wheat	1 cup scant
Puffed rice	1 cup heaping
Rice (cooked)	$\frac{1}{2}$ cup scant
Shredded wheat	$\frac{1}{2}$ biscuit

II MEAT—Any two of the following measured servings (12 c.c. each)

Beef, loin, med fat	4" x 4 $\frac{1}{4}$ " x $\frac{1}{2}$ "
Chicken, broiled	one-half
Chicken, stewed	breast or thigh plus leg
Cheese, cheddar	3 $\frac{1}{2}$ " x 2" x 1"
Codfish, fresh, cooked	$\frac{1}{4}$ cup
Eggs	2
Frankfurters, large	2
Halibut	4" x 2" x 1"
Ham, fresh	4 $\frac{1}{2}$ " x 3" x $\frac{1}{4}$ "
Heart, beef	2 $\frac{1}{2}$ " x 3" x 1"
Kidney, veal	$\frac{3}{4}$ cup
Lamb chop	3 med. size
Lamb roast	5" x 5" x $\frac{1}{4}$ "
Liver, beef	3" x 6 $\frac{1}{2}$ " x $\frac{1}{2}$ "
Mackerel, fresh	2" x 4" x 1"
Oysters, very large	3
Pork chop, thick	1
Salmon, fresh	3" x 4" x $\frac{3}{4}$ "

Salmon, canned	$\frac{1}{2}$ cup packed
Trout	2 $\frac{1}{2}$ " x 3" x 1"
Turkey, 2 slices	2" x 3" x $\frac{1}{4}$ "
Veal chop	1
Veal roast	3" x 2 $\frac{1}{2}$ " x $\frac{1}{8}$ "
White fish	2 $\frac{1}{4}$ " x 3" x 1"

III BREAD—Whole wheat, 5 slices (22 c.c. each)

IV EGGS—Two (55 c.c. each)

V MISCELLANEOUS—Any one of the following measured servings (2 c.c.)

Macaroni	$\frac{3}{4}$ cup
Spaghetti	$\frac{1}{2}$ cup
Rice	$\frac{1}{2}$ cup
Corn	$\frac{1}{2}$ cup
Plum Cake	1 $\frac{3}{4}$ " x 1 $\frac{3}{4}$ " x 1 $\frac{1}{4}$ "

B ALKALINE-ASH FOODS (Maximum amounts)

I MILK—One pint (72 c.c.)

II CREAM— $\frac{1}{4}$ cup (103 c.c.)

III FRUITS and VEGETABLES—(See below) (Not to exceed 25 c.c.)

C CONCENTRATED VITAMIN FOODS

I YEAST—2 cakes

II COD LIVER OIL—2 tablespoonfuls, or Halver oil, 2 capsules before each meal

III WHEAT GERM—2 tablespoonfuls to be added to cereal

Fruits and vegetables shall be chosen from the following lists only. Any combination of fruits and vegetables may be selected, but the total excess basic-ash in the selected combination must not exceed twenty-five c.c. daily.

Fruit	Amount	cc of excess basic ash
Watermelon	2 $\frac{1}{2}$ " x 2 $\frac{1}{2}$ " x $\frac{1}{3}$ "	27
Grapes	$\frac{1}{2}$ cup or 24 grapes	27
Pear	1 medium	36
Apple	1 small	37
Grape juice	$\frac{1}{2}$ cup	39
Lemon juice	$\frac{1}{2}$ cup	41
Cherry juice	$\frac{1}{2}$ cup	44
Orange juice	$\frac{1}{2}$ cup	45
Raspberry juice	$\frac{1}{2}$ cup	49
Peach	1 medium	50
Lemon	1 medium	55
Banana	$\frac{3}{4}$ cup or $\frac{1}{2}$ large	56
Orange	1 medium	56
Cherries	2/3 cup	61
Apricots	2 medium	68
Pineapple	2/3 cup diced	68
Muskmelon	$\frac{1}{2}$ cup	75
Rhubarb	$\frac{1}{2}$ cup	86
Vegetable		
Asparagus	$\frac{1}{2}$ cup	08
Green peas	$\frac{3}{4}$ cup	13
Onions	$\frac{1}{2}$ cup	15

Pumpkin	½ cup cooked	15	Salt-free butter	2 squares
Turnips	½ cup cooked	2.7	Milk	½ pint
Squash	½ cup mashed	28	Cream	¼ cup
Radishes	10	29	Sugar	Sugar
Mushrooms	½ cup canned	40	Beverage	Coffee
Cauliflower	2/3 cup cooked	5.3		
String beans	2/3 cup cooked	54		
Tomatoes	½ cup	56		
Cabbage	2/3 cup cooked, 1½ raw	60		
Tomato juice	½ cup	6.2		
Sweet potato	½ medium size	6.7		
White potato	1 potato 2½" diameter	70		
Lettuce	¼ head or 16 leaves	74		
Celery	4 stalks or ¾ cup	78		
Cucumber	1/3 cup sliced	79		
Rutabagas	½ cup mashed	85		
Carrots	5/8 cup	10.8		
Beets	2/3 cup	109		

LUNCH

Meat	Veal chop
Rice or substitute (see miscellaneous)	Steamed rice
Vegetables or salad	Sliced tomatoes
Fruit	Baked apple
Bread, whole wheat	1½ slices
Salt-free butter	2 squares
Beverage	Milk, 1 glass

DINNER

Meat	Roast beef
Vegetable	Potato
Vegetable or salad	String beans
Dessert	Tapioca cream pudding
Bread, whole wheat	1½ slices
Salt-free butter	2 squares
Cream	Cream
Sugar	Sugar
Beverage	Coffee

Note One pint of milk is to be used each day in any form.

The basic high vitamin A *alkaline-ash* diet has an excess alkaline-ash of 17.3 which likewise is varied daily to the point at which uric acid or cystine precipitation does not occur

High vitamin Alkaline-ash Diet

The purpose of the high vitamin alkaline-ash diet is to furnish an adequate high vitamin diet in which the total alkaline-ash exceeds the total acid-ash

The following *foods* in the designated amounts should be included in the diet daily

A ALKALINE-ASH FOODS

I MILK—One quart

II CREAM—½ cup

III FRUITS and VEGETABLES—Any combination of fruits and vegetables may be selected from the following list, but the total excess basic ash must total at least thirty-eight cc daily

Fruits	Amount	cc of excess basic-ash
Watermelon	2½" x 2½" x 1"	27
Grapes	½ cup	27
Pears	1	36
Apples	1 small	37
Currents (dried)	¾ cup	37
Lemon juice	½ cup	41
Orange juice	½ cup	45
Peaches	1 medium	50
Dates	7	5.5
Bananas	½ large	5.6
Oranges	¾ cup or 1 medium	56

Note A few samples of permitted fruit and vegetable combinations are

Orange juice, ½ cup	4.5
Grapes, 24	27
Cauliflower, 2/3 cup	5.3
Tomato, ½ cup	56
Potato, 1 medium	70
Total	251

Apple, one	37
Pineapple, 2/3 cup	68
Peas, ¾ cup	1.3

Total	250

In addition, the following acid and neutral foods may be used as desired

Acid foods Cranberries, flour (plain cookies), Pastry with custard or allowed amounts of fruit fillings, English walnuts, popcorn—(no salt), unsalted peanuts, unsalted crackers

Neutral foods Sweet butter, candy (no chocolate bars), lard, olive oil, salad oil, cornstarch, mayonnaise, sugar, tapioca, tea, coffee or Kaffee Hag, postum

The following list contains a few striking examples of foods which must be omitted because of their extremely high basic-ash content

Almonds, beet greens, dandelion greens, figs molasses, olive, parsnips, raisins, spinach, dried fruits and vegetables

Suggested Plan of Menu	Sample Menu
BREAKFAST	
Fruit	Grapes
Cereal and wheat germ	
Oatmeal and 2 tablespoonfuls wheat germ	Scrambled
Eggs, two	
Bread whole wheat	
Toast, whole wheat, 2 slices	

Cherries	2/3 cup	61
Apricots (fresh)	2	64
Pineapple	2 slices	68
Cantaloupe	1/3 melon or 1/2 cup	75
Rhubarb (cooked)	1/2 cup	86
Raisins (cooked)	1/2 cup	213
Fig chips (dried)	1/2 cup	80.7

Vegetable

Asparagus	12 - 5" stalks	08
Peas, (fresh)	3/4 cup	13
Onions	1/2 cup	15
Pumpkin	1/2 cup	15
Turnip	1/2 cup	27
Squash	1/2 cup	28
Radishes	10	29
Beans, canned		
kidney	1/2 cup	30
Potato chips	10 - 12 large	36
Mushrooms	1/2 cup	40
Cauliflower	2/3 cup	53
Peas (dried)	1/2 cup	54
Beans (snap)	2/3 cup	54
Tomato	1/2 cup or 1 med	56
Beans, canned		
baked	1/2 cup	60
Potato, sweet	1/2 medium	67
Potato, white	1 medium	70
Lettuce	1/4 head	74
Celery	4 stalks or 3/4 cup	78
Cucumber	1/3 cup	79
Rutabagas	1/2 cup	85
Carrots	5/8 cup	108
Parsnips	1/2 cup	119
Beans, lima, green	1/2 cup	140
Chard	1/2 cup	157
Beans, navy dried	3/4 cup	261
Spinach	1/2 cup	270
Beet greens	1/2 cup	270
Beans, lima, dried	2/3 cup	416

B ACID-ASH FOODS*I MEATS—Any two of the following measured servings*

Beef, loin, med. fat	4" x 4 1/4" x 1/2"
Chicken, broiler	one-half
Chicken, stewed	breast or thigh plus leg
Cheese, cheddar	3 1/2" x 2" x 1"
Codfish, fresh,	cooked 1/4 cup
Eggs	2
Frankfurters, large	2
Halibut	4" x 2" x 1"
Lamb roast	5" x 5" x 1/4"
Liver, beef	3" x 6 1/2" x 1/2"
Mackerel, fresh	2" x 4" x 1"
Oysters, very large	3
Pork chop, thick	1
Salmon, fresh	3" x 4" x 3/4"
Salmon, canned	1/2 cup packed
Trout	2 1/4" x 3" x 1"
Ham, fresh	4 1/2" x 3" x 1/4"
Heart, beef	2 1/2" x 3" x 1"
Kidney, veal	3/4 cup
Lamb chop	3 med size
Turkey, 2 slices	2" x 3" x 1/4"
Veal chop	1
Veal roast	3" x 2 1/4" x 1/8"
White fish	2 1/4" x 3" x 1"

II EGGS—one**III BREAD—Whole wheat—2 slices****IV CEREAL—Any one of the following measured servings**

Cornflakes	1 cup heaping
Cornmeal (cooked)	2/3 cup
Farina (cooked)	2/3 cup
Oatmeal (cooked)	1/2 cup
Puffed wheat	1 cup scant
Puffed rice	1 cup heaping
Rice (cooked)	1/2 cup scant
Shredded wheat	1/2 biscuit

C CONCENTRATED VITAMIN FOODS**I YEAST—2 cakes****II COD LIVER OIL—2 tablespoonfuls, or Haliver oil, 2 capsules before each meal**

In addition, the following alkaline and neutral foods may be used as desired

Alkaline foods Dairy products, including all cheeses, soups, except when made from meat stock, almonds, molasses, olives
Neutral foods Sweet butter, candy (no chocolate), cornstarch, lard, salad oil, sugar, coffee, tea, Kaffee Hag, Postum, olive oil, mayonnaise, tapioca.

The following list contains a few striking examples of foods which *must* be omitted because of their extremely high acid-ash content

Meat broths and soups, all breads and crackers except as listed above, all pastries and rich desserts, cranberries, peanuts, walnuts, popcorn, flour

Suggested Plan of Menu Sample Menu

BREAKFAST

While the patient is in the hospital, he

FORMATION OF URINARY CALCULI

1627

is taught to make determinations of the pH of the urine with an apparatus manufactured by the LaMotte Chemical Products Company. After leaving the hospital, the determination is made daily, using the second specimen voided before breakfast in order to avoid the effect of the alkaline tide and awakening respirations. The report of the daily readings is presented at monthly intervals to the physician who may alter the diet or medication in accordance with the level of the pH of the urine.

Vitamin A is administered in the form of haliver-in-oil or carotene-in-oil capsules while vitamin B may be added to the diet by prescribing yeast. By careful control of the pH of the urine, in addition to the other therapeutic measures commonly employed, the formation of recurrent calculi can be reduced to a minimum. Since this dietary regimen has been added to our postoperative armamentarium in

the last four years, the incidence of the recurrent formation of calculi has been reduced from 16.4 to 4.7 per cent.

Conclusions

- 1 Recurrent formation of calculi occurs with sufficient frequency to present a serious complicating factor in the surgical management of renal lithiasis.
- 2 By dietary means, the precipitation of salts essential for the formation of calculi can be prevented.
- 3 Each patient must be individualized and the closest cooperation between the physician and the patient is essential.
- 4 During the last four years, the incidence of recurrent calculi has been reduced from 16.4 to 4.7 per cent by the use of a dietary regimen in conjunction with other therapeutic procedures which have been employed in the past.

Discussion

ganisms, animals developed stones, does not permit us to ignore entirely the part which infection may play.

The *Proteus bacillus* offers a serious problem when observed in the presence of recurring lithiasis. What part the infection plays is not clear. From a study of diverticula in the bladder of prostatic obstruction, and of obstruction in the ureters, we learn that stasis is a frequent concomitant work of recurrent lithiasis. The excellent work of Chute has called our attention to the increased activity of the parathyroid gland as a factor in the disease. However, it is not impossible for hyperparathyroidism and a dietary deficiency to occur in the same patient.

Many excellent articles have been published and much work done on these prevalent theories relative to the causation of renal calculus and it is interesting to find that, in spite of their wide divergence, they are after all rather closely interrelated. Probably no single factor is instrumental in the production of all stones. The experimental work of Dr. Higgins in

Dr. LEO E. GIBSON, Syracuse—I am very glad to have the opportunity to hear Dr. Higgins' paper and like all of his contributions, it has been very interesting and instructive. Regardless of whether one believes in his theory or not, he has done a great amount of hard work which certainly has been very progressive in nature. Since the time that a urinary stone was identified as a factor producing renal degeneration, physicians have vainly sought for the etiology of its formation and a method for its dissolution.

The trend of most recent contributions to this subject would lead one to believe that the fundamental etiological factor involved is of a chemical nature rather than bacteriologic. It is evident that some disturbance of metabolism affecting the urine either through the colloids or the effect upon the epithelium, permits precipitation of the stone forming element. On the other hand, the work of Rosenow, demonstrating streptococci in the teeth of patients forming recurring stones, and following inoculation of cultures of these or-

vitamin A deficiency has given priority to the dietary theory as the most satisfactory mechanism of calculus formation

I believe that Dr Higgins attempts to visualize the kidney as an organ which has different states of being according to those of the body in which it lies. Such persistent body conditions as dietary deficiency and hyperparathyroidism must produce certain changes in the kidney. He regards calculus as an affect produced by such changes and directs his efforts toward eliminating the cause. The mere operative procedure of removing calculi is only one phase in the correct management of renal lithiasis.

In his study he has not abandoned the older conceptions of recurrent calculus formation but he has searched for their presence and if found they are properly treated. He considers focal infections as well as the infected genitourinary tract. Tests are made for the presence of cystinuria, phosphaturia, and oxaluria. He finds the *Proteus bacillus* infection a difficult one to treat by his method or any other method. Stasis is ruled out by means of the intravenous pyelogram, and a ureteral stricture, if found, is dilated in the proper manner. The factors of urostatics and infection which are known to be associated with calculus formation in the majority of cases must not be disregarded by the discovery and application of this new dietary regime.

I think we are all a bit surprised by the prevalence of the vitamin A deficiency found by Dr Higgins. This discrepancy in our work may be due to the fact that we have not been diligent enough in seeking the evidence of that disturbance. My understanding is that it is necessary for only a mild degree of vitamin deficiency to exist over a long period of time in order

to produce calculus formation. Where a vitamin A deficiency occurred it is not invariably associated with calculi.

One thing which is not very clear to me is the origin of the primary initiating lesion. It is assumed that there is a primary papillary or calyceal ulceration caused by vitamin A deficiency. Is there sufficient proof that this lesion is not caused by the infection which is present with most stones? In those cases without infection some trophic or allergic change might be responsible. We have been able to relieve infection by increasing the acidity of the urine. The question arises then as to how much importance one may attribute to the acidity factor and to the vitamin.

There are one or two precautions which might be emphasized in the administration of acid producing drugs. First, the administration of ammonium chloride in the presence of urea splitting organisms produces additional urea for the organisms to work on, the ammonium chloride being a nitrogenous compound. One would expect the condition to be aggravated rather than improved. A production of too much acidity as shown by reducing the pH too strongly, may cause a precipitation of uric acid salt. It is necessary, therefore, to carry out a thorough and diligent study of the urine of these patients at all times.

I would like to ask Dr Higgins how long he keeps these patients on this dietary regime and what are the indications, if any, for discontinuing the diet in the patient with a tendency toward recurrent calculus. A second question, in those cases of *Proteus* infection in which he does a pyelotomy or a nephrotomy, does he find that a secondary infection, which is probably *Staphylococcus* from the skin, becomes persistent in the kidney?

DENTAL OFFICE IN A COVERED WAGON'

The State of Indiana is sending a streamlined trailer dental office on the road to give needy children sound teeth.

The trailer, equipped with dental chair of latest design, laboratory, sterilizer, work bench, instrument cabinet, hot and cold running water, clothes closet, leather divan and modern lighting facilities, has been planned jointly by the Indiana State Dental Association and the State Bureau of Child and Maternal Health.

Thousands of children between three and ten years old whose parents are on relief are to get dental attention when the trailer reaches their home communities. The trailer is to work only in smaller

towns where clinics are not available to the needy.

Services are to be limited to prophylaxis, cement and amalgam fillings and extractions. Cases will be designated by local health agencies and dentists.

Dr Marv H. Westfall, head of the dental division of the Bureau of Maternal and Child Health, says the decision to equip a dental trailer results from a survey by Indiana dentists showing that large numbers of children in so-called "backward" counties have little or no dental care in their early years.

The only way to cope with this situation, she says, is to take the dentist to the child.

TREATMENT OF ALOPECIA AREATA

HERBERT H BAUCKUS, M D, CARL F SIEKMANN, M D,
and ALBIN V KWAK, M D, *Buffalo*

It is indeed difficult to frankly evaluate treatment in such a capricious disease as alopecia areata. At the outset the writer and his associates wish to emphasize that their tendency is to err on the side of therapeutic nihilism and that their conclusions are drawn, not from recent favorable cases but from recorded observations during several years of active private and clinical practice.

It seems that the therapy of the hair is still rather sadly neglected by the modern practitioner and dermatologist. Undoubtedly it is partly our fault that the public goes to other courses for advice and treatment—even for diagnosis. So many are the varied and new chemical substances constantly being added for use in the beauty parlor that one must ever be on the alert to detect the etiology and new sources of allergic dermatitis and dermatitis venenata. With these thoughts in mind we write to briefly outline a treatment which we think gives us unexpectedly good results in alopecia areata.

No one treats fairly and well without having etiology constantly in mind. Unfortunately we know little about the cause of the disease in question. It seems that the trophoneurotic etiology inter-related with endocrine toxic factors now has quite general acceptance. There are of course reasons for belief in the parasitic or infectious theory¹. Some of the apparently epidemic cases have been thought to be due to manipulation as shown by Davis². We have been especially interested in the relationship between the endocrines and alopecia areata. In these cases it appears that a toxic factor is a necessary adjunct in the process. Richova³ suggests that the clinical picture of thallium acetate alopecia is identical with that of alopecia areata caused by hypothyroidism and records a case of thallium poisoning with the decreased metabolism and general features of hypothyroid disturbance. Kugelmass⁴ reports a case recovering with care of hypothyroidism in a child and

Hollander⁵ a case regarded by him as endocrine dysfunction due to syphilitic toxin. Ayers⁶ reports a case of vitiligo and alopecia areata associated with severe hyperthyroidism. The effect of the pituitary has been observed by Bengston⁷ and by Lord⁸. The general subject of etiology is intriguing and the literature voluminous, but the fact remains that we do not definitely know what causes alopecia areata and there are some who are not convinced of the efficacy of any kind of treatment.

In attempting to mostly confine this brief presentation to a therapeutic method, we will dismiss the important subject of etiology with a report of the following cases.

A young man of twenty, apparently in good health came in accidental contact with an electric current sufficient to throw him to the floor and render him momentarily unconscious. He had no further symptoms until exactly four weeks later several patches of alopecia areata appeared in the scalp. New lesions appeared rapidly and within a month alopecia areata universalis was present. After six months this patient began to recover and in two years was well.

With the usual variations for individual patients our method of treatment has been as follows:

Explanatory talk with the patient or in the case of very young patients, the parents or guardian. This is intended to guard against loss of confidence from the appearance of new lesions and is generally designed to put the patient in a more cheerful and optimistic mental state. Of course, rash promises are harmful. We think that the more severely worried, pessimistic, and hypochondriac sufferers have poorer results. Possibly this is putting the cart before the horse. But we believe there is much to mental rest in caring for this disease. Patients, young and old, are urged to have plenty of sleep—early to bed and with fresh air. We urge physical rest and freedom from exhaustion with effort to live out of doors in seasonable weather. We advocate avoidance of alcohol, and especially in children a well-balanced diet that is vitamin

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

sufficient. Adult patients usually like to know about the question of syphilis, and physical examination and laboratory tests, here again, are much better medicine than optimistic assurances. Some may question the necessity or value of the above general measures. We think they are of much aid and are somewhat neglected. But most physicians agree that local stimulating treatment is of value. In 1920 Howard Fox⁹ reported a series of fifty cases treated with ultraviolet ray. This article aroused much interest in the treatment of alopecia areata and marked a distinct advance in therapy. We regard the efficacy of this treatment due to its production of an erythema. In children there may be an additional internal effect. We think the erythema of ultraviolet ray endures longer and is more easy to control than that caused by other external irritation. Treatments at intervals of as long as one to three weeks will dissipate the sad white and bring forth the more welcome pink of the recovering scalp. We do not think daily or tri-weekly applications of ultraviolet ray improves the therapy. We attempt to avoid vesication. Even with the ultraviolet ray treatment we seek to have patients apply a general mild stimulating lotion to the scalp each night. We like bichloride of mercury to be in the lotion, and often employ the following simple preparation: Hydrarg bichlor 45, liquor carbonis detergens 6.00, alcohol sixty per cent qs ad 180.00. We use ammoniated mercury ten per cent in ungt. aq. rosae to the affected areas in the bearded region and in the eyebrows. We think the lesions of the beard are more difficult to treat than those of the scalp. If ultraviolet ray is not available, substances such as creosote, tricresol, cantharidis, spirit of turpentine, and chrysarobin may be used. Beerman¹⁰ reports a successful case treated with dihydroxy anthrasol 25, plus ultraviolet ray. We think these irritants ought not to be employed in sufficient strength to cause vesication. A severe reaction, necessitating interruption of treatment for several days, interferes with the production of a desirable stable erythema. We think that recurring cases of alopecia areata, the more generalized types, and middle-aged adults, are slower to respond to local treatment.

Three years ago we began to routinely employ small doses of desiccated thyroid extract in alopecia areata in private practice. There appeared to us a striking improvement in our therapy, and the comparison of our private case results with those of the clinics where therapy was the same except that thyroid was not given,

encouraged us to regard thyroid as a welcome adjunct in the therapeutic armamentarium. We realize the fact that thyroid is used with poor success in many atrophic diseases of the skin other than in myxedema. We do not note that many patients with alopecia areata have a low basal metabolism, decreased nitrogen exchange, or the clinical signs of more marked thyroid deficiency. We have tried and discarded other endocrines, including anterior lobe pituitary. Thyroid does affect the hair and occasionally the surviving hair of alopecia areata appears myxedematous. But we did not use thyroid with the idea alone of treating deficiency but with the plan of securing from it the slight stimulation which in many ways apparently has to do with the regrowth of the hair. We eliminated patients having clinical or laboratory tests indicative of hyperthyroidism unless the administration of the drug was approved by the internist. All other cases were given the treatment. The initial dose to adults and children over ten was one grain once a day of desiccated thyroid representing five grains of fresh gland substance containing 0.3 per cent iodine in organic combination. This dose was not increased for at least two weeks, but in suitable adults two grains of desiccated thyroid were prescribed at the end of that time, this dosage was kept up for a month. At the end of this time the dose was reduced to one grain. We try to avoid stimulation that would be sensible to the patient. We have not been impressed with the use of simple iodine in this disorder. Dealing with the question of alopecia areata alone, we think large doses of thyroid, especially early, to be harmful. We have not used free thyroxin. Since the addition of this type of thyroid medication in our work with alopecia areata we have concluded as follows:

First, and most marked, that new lesions were not so prone to develop in early cases. *Second*, the hair began to regrow much more quickly in the bald areas. *Third*, recurrences after cessation of treatment were as common as under our old methods. *Fourth*, the regrowth of hair in recurring cases was more easily brought about. *Fifth*, the response in adults showed great improvement over our former experience. We did not feel justified in treating alopecia areata with thyroid alone especially since we did

not think we were necessarily dealing with a hypothyroid process

The stimulating combination of the external production of erythema plus a possible internal endocrine encouragement by the thyroid seems to us to present a plausible explanation and reason for use of this method. Of course this paper does not pretend to display a new theory nor to make claims for unusually brilliant cures. We have purposely omitted the presentation of cases that stand out as striking examples of cure in this disease. Every physician has had them. Time and further experiments may rudely change our opinions and beliefs. We merely offer

the therapeutic suggestion that thyroid be more routinely employed in the treatment of alopecia areata and in certain other diseases of the hair

Discussion

DR. FRANK C COMBES, *New York City*—Dr Bauckus has given us some valuable suggestions in the treatment of this capricious affection. He has not offered a new or spectacular method of handling the disease, but has presented some personal impressions gained in the management of a small series of cases observed both in his private practice and in the hospital. Undoubtedly there are many of us who have obtained equally as good results with other methods. In fact, I have frequently doubted whether my treatment of a case of alopecia areata was ever responsible for the regrowth of hair. At an informal discussion among a group of dermatologists several years ago, the opinion was expressed by some that they could not conscientiously treat a case of this disease, feeling that the new growth of hair would occur notwithstanding any medication which they might administer. This is rather an extreme view as a patient applies to his physician expecting relief and it is the duty of the physician to grant it to the best of his ability. This is especially true in a disease of this nature which is probably trophoneurotic in origin.

The prognosis in this disease is usually always good. If the patient is under forty years of age, you may confidently predict a complete recovery. There are so few exceptions that you may take the risk. The prognosis must not be too guarded. If it is, it is liable to effect the zeal of the patient in carrying out the prescribed treatment. Dr Bauckus has mentioned the psychic element in his therapeutic attack. This is of essential importance. Cooperation with the patient is the only way to hold him.

Since the disease so frequently follows mental shock, I have always wondered whether the methods employed in this treat-

ment did not effect the patient in a psychic manner. I doubt whether there are two persons in this room who treat it in the same way. Yet our results would probably compare favorably. Dr Bauckus believes that his cases are helped by thyroid medication. Possibly so, but the patients should be kept under observation during its administration which after all is essential to their mental well-being. The same may be said for ultraviolet radiation. Personally I prefer a one-quarter to two per cent bichloride of mercury solution in alcohol as a local counterirritant.

One element in the treatment is essential. Do not persist in the use of one method if it is not producing the desired result. Humor the patient by making a change. If this is not done, he will probably change not only his medicine, but also his physician. As the last medicine gets all the credit, so does the last physician.

DR. HERMAN GOODMAN, *New York City*—Celsus, as far back as the first century, recorded the observation that loss of hair—the pattern of alopecia areata—was of two types. It may be recalled, incidentally, that one of the synonyms for alopecia areata is alopecia celsi, or area celsi, referring to this learned gentleman.

Celsus noted that the prognosis of alopecia areata along the periphery of the scalp, which he called ophiasis type or band or ribbon or rein type, was poorer than the prognosis for loss of hair in the alopecia areata manner centrifugally in the scalp.

It would appear that this observation of Celsus was of greater importance than has been given it for many years.

Let us examine the nerve supply of the scalp. It is very simple to do this on the

sufficient. Adult patients usually like to know about the question of syphilis, and physical examination and laboratory tests, here again, are much better medicine than optimistic assurances. Some may question the necessity or value of the above general measures. We think they are of much aid and are somewhat neglected. But most physicians agree that local stimulating treatment is of value. In 1920 Howard Fox⁹ reported a series of fifty cases treated with ultraviolet ray. This article aroused much interest in the treatment of alopecia areata and marked a distinct advance in therapy. We regard the efficacy of this treatment due to its production of an erythema. OXYGEN CONSUMPTION IN ORGANIC PSYCHOSES

J NOTKIN, M D, *Poughkeepsie*
Hudson River State Hospital

While the etiology of the organic psychoses is well-established the causal factors underlying some of the organic processes, as in arteriosclerosis and senile brain changes, are still unsettled. Most of the studies carried out in arteriosclerosis tend to indicate the possibility of metabolic disturbances. Among the outstanding investigators who are in favor of this theory are Kast¹ and Aschoff². Others like Hober³ and Glaser,⁴ emphasize the emotional factor and its effect on the cholesterol metabolism as the first step in arteriosclerosis. The relationship of cholesterol metabolism to arteriosclerosis was demonstrated by Autschkow and Chalatow^{5,6}. In senility the involutional processes may play an important part but there are still many problems to be solved.⁷ The degree of oxygen consumption being an indicator of the metabolism of the organism, basal metabolism determinations may give some lead to the mechanisms operating in the arteriosclerotic and senile processes. The present communication deals with the results of basal metabolism studies carried out in patients with various organic psychoses, such as arteriosclerotic and senile psychoses, dementia paralytica, alcoholic psychoses, and in other miscellaneous organic acute and chronic reactions caused by a variety of factors including head trauma, metabolic and somatic diseases, degenerative brain and cord changes, and exogenous poisons. Except for the utilization of Benedict's^{8,9} findings in a relatively small number of elderly normal people it was practically impossible to secure suitable controls. The aged schizophrenic institutional material or general hospital patients could not well serve the purpose in view of the additional elements involved. The study was made in two hospitals, one situated in New York City, the other in a rural district.

One hundred forty-seven patients with arteriosclerotic psychoses were tested. There was a tendency toward minus readings in the male group. Almost forty-

five per cent of the combined groups of men in both institutions showed very low basal metabolic readings (Tables I-IV). There was a relatively small percentage with high readings.

In relation to age there is a tendency to lower ratings in the older people of the urban group, while the rural patients showed a relatively low oxygen consumption rate in the sixty to seventy age group (Tables V-VIII). In relation to blood pressure the urban male group had the lowest average metabolic rate in the 150 to 180 intermediate blood pressure group while the rural male patients showed a relatively low average in the low blood pressure group (Tables IX-XII).

The group of fifty-three arteriosclerotic women patients were all inmates in the rural hospital. They showed equal average metabolic readings in all age groups, and a somewhat low average rating in the high blood pressure group (Tables XIII-XV).

There were definite differences in the results obtained in the two institutions. This disparity is somewhat difficult to explain. Regional and nutritional factors may have to be taken into consideration. In favor of such possibilities is the study made by Hafkesbrung and Bogstrom¹⁰. They found the basal metabolism in individuals residing in New Orleans fourteen to eighteen per cent lower than the accepted standards. Earle¹¹ also obtained in white residents of Hongkong and Peking a basal metabolism rating seven per cent below Du Bois' standards.

The patients with senile psychoses, especially the men, showed a pronounced tendency toward minus readings (Tables XVI and XVII). Very low ratings were recorded in fifty per cent of the male group. Correlated with age the male patients showed the lowest readings in the relatively young group, while the women patients had practically identical ratings in all age groups (Tables XVIII and XIX). Compared with the blood pres-

basis of toxicity of certain drugs to the sympathetic nerve endings. Let us go back to the effect which thallium acetate has on the hairy scalp.

First Depending upon the physiological age group, for example, before and after puberty. It is well-known that thallium acetate in proper dosage has the effect in preadolescence of causing the loss of hair generally from all the scalp.

Second Postadolescent persons given a similar dosage of thallium acetate have loss of hair which excludes the periphery of the scalp. This would indicate that the sympathetic nervous system which controls all the scalp in preadolescence has lost control of the hair growth at the periphery of the scalp in post-adolescence.

Further evidence of this change in nerve control is offered by the fact that long after the person has lost the hair in the male pattern known as the Hippocratic manner, the periphery of the scalp which retains the hair shows much more rapid growth of hair per unit of time than previously. With this groundwork, treatment of alopecia areata must depend upon physiological age.

If loss of hair occurs in a person before sexual maturity, treatment should be directed towards stimulants of the sympathetic nerve endings no matter where the loss of hair in the scalp occurs. Unfortunately, such sympathetic nerve stimulants are not definitely known either in pharmacology or in dermatology. On the basis of experience we have utilized pilocarpine hydrochloride, both topically and by local injection into areas of alopecia areata. Our success or failure with this method, unfortunately, has been no different than any other methods utilized.

We have also sought to eradicate what might conceivably be the cause of the sympathetic ending depressant action.

In our experience the heavy metals have been a fertile cause, and elimination of the heavy metals through the administration of sodium thiosulphate has attended the return of the hair. In this connection, it is important to note that loss of hair at the periphery of the scalp is resistant to treatment.

Our conclusion has been that such loss of hair resulted from some trauma to the central nervous system which was not relieved or released by the solvent action of sodium thiosulphate.

By and large, external treatment to the scalp by means of antiseptics, irritants, and the usual pharmacological messes miscalled "hair tonics" is useless. The specifics for hair growth proposed from time to time as hydrolyzed horn (a German importation), cholesterol, and lecithin have always failed in restoring hair in bald areas. We are

most pessimistic regarding purposeful repeatable hair regrowth. We still await control experimentation through treatments of half a head, if such is possible and elimination and regrowth of the treated side or the treatment of one or two identical twins with restoration in the treated twin. One might be facetious. One experiment in therapy for alopecia areata which would tend to be convincing, would be the treatment of three of the five quintuplets, provided they had alopecia areata and further that only the three treated ones had restoration of hair.

DR HOWARD FOX, *New York City*—The main difficulty in the treatment of alopecia areata is that we do not know any more about its causation than did Celsus in A.D. 25. It is very difficult to evaluate a therapeutic method in a disease which runs such a capricious course as alopecia areata, resulting in most cases in a spontaneous cure. As Dr Bauckus has mentioned my series of cases treated by quartz lamps, I would say that I did not ascribe any peculiar virtue to ultraviolet light but merely considered that the use of quartz lamps constituted a cleanly and convenient method of causing local stimulation. I should like to call attention to the unfortunate publicity given to an article on the treatment of baldness (mostly alopecia areata) by aututrin. To prove or disprove the author's contentions it was necessary to undertake a great amount of experimentation. This has resulted in a unanimous conclusion that this drug is of no value in alopecia areata.

DR. HERMANN FEIT, *New York City*—At the Eighth International Congress of Dermatology in Copenhagen (1930) I showed in cooperation with Drs Throne and Myers an abnormal basal metabolism in sixty-two per cent of 162 patients. The abnormal minus findings were about twice as large as the abnormal plus findings.

There was no relationship between the basal metabolic findings and the clinical picture. For example, a case showing only one small spot might give a minus twenty, and a case of complete loss of hair on the contrary give a plus normal.

The work I am doing now is based on the conception of alopecia areata as a functional disorder of the sympatheticus. Sympathin, the so-called sympathetic substance is created on the synopsis of the sympathetic nerve endings with the capillaries of the skin. Introduction of the vagus substance has given very encouraging results in a sufficient number of total and local cases of alopecia areata to warrant continuation of our work.

OXYGEN CONSUMPTION IN ORGANIC PSYCHOSES

J NOTKIN, M D, *Poughkeepsie*
Hudson River State Hospital

While the etiology of the organic psychoses is well-established the causal factors underlying some of the organic processes, as in arteriosclerosis and senile brain changes, are still unsettled. Most of the studies carried out in arteriosclerosis tend to indicate the possibility of metabolic disturbances. Among the outstanding investigators who are in favor of this theory are Kast¹ and Aschoff.² Others like Hober³ and Glaser,⁴ emphasize the emotional factor and its effect on the cholesterol metabolism as the first step in arteriosclerosis. The relationship of cholesterol metabolism to arteriosclerosis was demonstrated by Anitschkow and Chalutow.^{5,6} In senility the involutional processes may play an important part but there are still many problems to be solved.⁷ The degree of oxygen consumption being an indicator of the metabolism of the organism, basal metabolism determinations may give some lead to the mechanisms operating in the arteriosclerotic and senile processes. The present communication deals with the results of basal metabolism studies carried out in patients with various organic psychoses, such as arteriosclerotic and senile psychoses, dementia paralytica, alcoholic psychoses, and in other miscellaneous organic acute and chronic reactions caused by a variety of factors including head trauma, metabolic and somatic diseases, degenerative brain and cord changes, and exogenous poisons. Except for the utilization of Benedict's^{8,9} findings in a relatively small number of elderly normal people it was practically impossible to secure suitable controls. with increased blood pressure (Tables XX and XXI)

Although the low averages approximate those obtained by Benedict in a group of normal old people our findings tend to indicate that the gradual decrease in the oxygen consumption seems to reach its limit at the age of seventy. However, the psychic element of our patients has to be reckoned with in making comparisons with so-called normal controls.

A group of sixty-five untreated parietic patients showed a prevalence of minus readings amounting to 83.07 per cent and a high incidence of 58.46 per cent of very low readings, a low average reading in the 60 to 40 age group and in the 170 to 130 blood pressure group (Tables XXII-XXIV). In a group of 106 treated patients the percentage of very low readings was almost half of that recorded in the

untreated group (Tables XXV-XXX). It may be of some interest that normal basal metabolic ratings were obtained in patients who improved physically but not mentally following the usual treatment with malaria, arsenicals, and bismuth. There were slight differences in the average readings in both sexes, both in relation to the age and blood pressure (Tables XXXI-XXXIII). The significant findings in the tabetic group are the low average metabolic readings in the 190 to 150 blood pressure group and in the 60 to 51 age group, the relatively higher average in the 130 to 120 blood pressure group as compared with the similar group in the cerebral type (Table XXXIV). It is of interest that the combined treated group of men and women and both groups separately showed almost identical average metabolic readings.

In the alcoholic group there was a predominance of minus readings amounting to seventy-five per cent, very low readings in about forty-five per cent, and a tendency to approximately normal averages in the chronic cases where the toxic element of the alcohol is no longer present. Low oxygen consumption rates were recorded in the acute psychoses (Tables XXXV-XXXVIII).

In a small group of cases with traumatic psychoses there was a definite prevalence of very low readings (Table XXXIX). Low readings were also observed in single cases with psychoses due to veronal and illuminating gas poisoning.

In a group of cases with psychoses due to various types of brain and cord changes two cases of paralysis agitans, two siblings with Wilson's disease, and one case of Charcot-Marie-Tooth, had basal metabo-

ism readings within normal limits, while another case of Charcot-Marie-Tooth and a case of Pick's disease, showed low readings. A case of Huntington's chorea had a high rating. A few other cases with psychoses caused by somatic or metabolic disorders had with a few exceptions normal basal metabolic rates.

The question whether the lowered oxygen consumption in our cases with arteriosclerotic and senile psychoses is primary or secondary must still be left open. The decreased use of oxygen may be secondary to the nutritional disturbances caused by the waste product accumulation and vessel wall changes. A lowered oxygen use in itself, however, may give rise to similar structural changes. The low basal metabolic rates obtained by Benedict in elderly mentally normal people without external signs of senile or arteriosclerotic changes is a point in favor of this theory. Involutional changes, particularly in thecretory system, may be the underlying cause. Such an assumption requires, of course, an elucidation of the factors which determine the process of involution especially at an earlier age.

In dementia paralytica, alcoholic and traumatic psychoses and in all other organic reactions in which the underlying

arteriosclerotic and senile psychoses was found to be decreased. Patients with arteriosclerotic and senile psychoses residing in the metropolitan area showed a greater tendency toward low basal metabolism ratings than patients living in rural districts.

In untreated patients with dementia paralytica the basal metabolism readings tend to be low. In treated patients with

dementia paralytica there is an improvement in the basal metabolism.

In acute alcoholic psychoses the basal metabolism is decreased, while in the chronic institutional cases the oxygen consumption rate is normal.

In traumatic psychoses the basal metabolism is lowered.

In other acute and chronic organic psychoses with known underlying causal factors the basal metabolism is not characteristic. However, relatively few patients of this type are available in state hospitals for an accurate study.

The question whether the lowered

Discussion

DR. S BERNARD WORTIS, *New York City*
 —Dr Notkin has presented us with a most unusual group of data on the basal metabolism in various organic psychoses. It is well-known from the work of Lusk, DuBois, and Benedict that basal metabolism varies considerably according to age, sex, health or disease, the effects of drugs and diet, and the effects of emotional disturbance. Benedict¹ showed that emotional disturbance caused a marked increase in the metabolism of a normal human subject which

did not subside for several days. Pioneer work by Magnus-Levy and Falk in 1899 clearly indicated that advancing age is accompanied by a decreased basal metabolism.

As you all know, the commoner conditions associated with increase in the basal metabolism are (1) thyrotoxicosis, (2) leukemias (with increased nitrogen catabolism), (3) polycythemia, (4) some cases of hyperpituitarism in the active stage, (5) heart failure associated with dyspnea and overwork of the respiratory muscles, (6) fever, (7) pregnancy in the last few weeks, and (8) emotional disturbances.

2	-12 0	Empyema
3	-28 3	Empyema
4	+16 3	Lobar pneumonia
5	-18 6	Lobar pneumonia

Certain medicaments also increase the

basal metabolism these are (1) thyroid gland by mouth or thyroxine by vein, (2) certain nitrophenols, and (3) 3,5-diiodo-L-thyronine. Caffeine and adrenaline stimulate metabolism but have little or no effect on the B.M.R. because their action is not apparent fourteen hours after injection—when the B.M.R. is taken.

The commoner conditions associated with decrease in the basal metabolism of the individual are (1) hypothyroidism (including myxedema and cretinism), (2) under-nutrition, and (3) nephritis with edema. Some drugs lower the basal metabolic rate, these are (1) iodine, (2) sodium or ammonium fluoride by mouth or intravenously, and (3) morphine.

Steinberg² has shown in normal people that increase in mental speed is not related to increase in the basal metabolism—and this one might expect considering the small amount of energy expended in mental activity.

Dr Notkin has shown us that in organic disease of the brain there is a general depression of the body metabolism. He has given us indisputable proof, in the organic psychoses, that the depression of body metabolism is dependent upon depression of brain function. We should add to this our knowledge that emotional upsets can increase basal metabolism.

Changes in the brain, the body (the endocrines, etc.) and the environment can produce changes in the activity of the organism. Dr Notkin has shown us how important the central structural control of metabolism is. Let me congratulate him on a most valuable contribution to our neuropsychiatric knowledge.

ANTIVENIN SERUM

Painful as it may be to some to have this knowledge divulged publicly, spirituous liquors are not the best antidote for snake bite. The chief service of the remedy is to render the snake-bite person more or less indifferent to his predicament, or enthusiastic perhaps, about being bitten again, according to Dr Lee D. Cady, author of "Snakes in the Service of Science" in *Hygeia*.

The antivenin serum injection of the proper sort is by far the better for the saving of life or amelioration of symptoms.

Of course it has been known for many years that if one had the good fortune to survive the first bite, one has a much better chance to live after the second poisoning

from another snake of the same species. This may be comforting knowledge, but the hard-bitten professionals do not have their favorite rattlesnake give them an eye opener of venom every morning.

Venomous snake secretions have, in the main, three poisonous elements in them. These vary markedly with the species of the snake, and the kind of antivenin to be used in a snake accident must fit the case. The colubrine snake venoms possess a predominantly neurotoxic action, that is, they are poisonous to the nervous system.

The venom of the daboia (*Viper Russellii*) and the Bungarus have an interesting ability to cause blood to clot very quickly, even while circulating.

SURGICAL TREATMENT OF ACUTE CHOLECYSTITIS

GEORGE J HEUER, M D, *New York City*

From the Department of Surgery of the New York Hospital and Cornell Medical College

In discussing the surgical treatment of acute cholecystitis, I do not propose sweepingly to condemn older and more conservative methods of treatment and solely to advocate more radical methods. Rather I propose to present the results of my efforts to lower the mortality in this disease and to recount the data relevant to the subject which I have gathered from the literature. By so doing, I shall hope to convince you that a too conservative attitude toward the treatment of acute cholecystitis has contributed to its mortality and should be replaced by a more elastic viewpoint which recognizes the necessity of resorting to surgical treatment in the acute stage of the disease.

By the conservative attitude, I refer to the still widely-accepted opinion that the welfare of the patient with acute cholecystitis is best conserved by waiting for the acute process to subside and to operate, if operation is contemplated, after the disappearance of the acute symptoms. It is based chiefly upon two suppositions (1) that the acutely inflamed viscus generally takes care of itself and that, therefore, complications as gangrene of the gall-bladder, perforation, peritonitis, and extracholecystic abdominal abscess are rare and (2) that the danger to the patient in operating during the acute stage of the inflammatory process is definitely greater than in an interval when the inflammatory process has subsided.

Those of you whose experience goes back some years will recall similar expressions with reference to acute appendicitis. At one period in the development of its treatment, it commonly was stated that the dangers of operating in the acute stage of the disease were greater than those of gangrene and perforation of the appendix, and it was the practice of many to await an "interval" before its removal. While I do not wish to emphasize too strongly the similarities between acute appendicitis and acute cholecystitis, certain analogies do exist, and

it may not be inappropriate to discuss with reference to acute cholecystitis, the propositions which at a previous period were discussed with reference to acute appendicitis. These are three

1 Is it possible, from the clinical symptoms in acute cholecystitis, to determine the pathological course of the inflammatory process in the gall-bladder—whether this is toward restitution or toward gangrene and perforation?

2 Is it true that the acutely inflamed gall-bladder so rarely undergoes gangrene and perforation as to disregard these complications as important factors in the treatment of the disease?

3 Is the danger to the patient of operating in the acute stage of the disease before gangrene and perforation have occurred greater than the dangers of gangrene and perforation, the result of a waiting policy?

These propositions I shall discuss in the order named

1 In a series of eighty-nine cases of acute cholecystitis at the Cincinnati General Hospital which I studied and briefly reported in 1930¹ and which subsequently were more carefully studied and reported by Zininger,² it was found that (a) thirty-five cases were so ill at the time of admission that immediate operation was performed. The later comparison of the clinical symptoms with the pathological findings in the gall-bladder in these thirty-five cases seemed to show a relationship between a high leukocyte count and empyema of the gall-bladder and a relationship between the duration of the attack and the extent and severity of the inflammatory process in the gall-bladder. But, aside from these two inconstant relationships, there appeared to be no definite relationship between the symptoms and the pathological process. (b) Fifty-four cases were kept under observation from one to twelve days and in the majority of cases because the symptoms and physical signs were mild and warranted the opinion that the disease would subside. In twenty of the fifty-four cases, or 37 per cent the attacks subsided, in nineteen, or thirty-five per cent of the cases the attacks failed to subside after an interval of

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1936

twelve days and operation was deemed necessary, in fifteen, or 277 per cent, the attacks became progressively more severe, and in four perforation of the gall-bladder occurred. Of the fifty-four cases with mild symptoms on admission, twenty or thirty-seven per cent showed a resolution of the pathological process in the gall-bladder, while thirty-four or sixty-three per cent showed progress of the disease to empyema of the gall-bladder (12), to gangrene (2), and to gangrene and perforation (6), and often in the presence of mild symptoms.

In a second series of 126 cases of acute cholecystitis admitted to the surgical wards of the New York Hospital, the lack of a definite relationship between the clinical symptoms and pathological findings is also apparent. It is true that the studies made in this series of cases were not so prolonged as in the Cincinnati series. I find that of the 126 cases about seventy per cent were subjected to operation less than twenty-four hours after admission, while thirty per cent were observed forty-eight hours or more before operation was performed. Nevertheless, I have sufficient evidence to show that the severity and course of the clinical manifestations of the disease bear no constant relationship to the severity and course of the pathological process in the gall-bladder.

In a group of twenty-one cases in which the gall-bladder at operation showed a subacute or resolving inflammatory process, the average temperature was 3°C above normal, the average leukocyte count 10,400 and the gall-bladder was enlarged and palpable in twenty-eight per cent of the cases (Temperature normal— 37°C —or subnormal in nine, 37 to 37.4 in seven, 37.4 to 38 in five. Leukocytes normal—7500—or subnormal in three, 7500 to 9000 in seven, 9000 to 15,000 in nine, above 15,000 in two. Gall-bladder palpable in six of twenty-one cases or twenty-eight per cent.)

In a group of seventy-two cases in which the gall-bladder at operation showed an acute inflammation without evidence of regression the average temperature was 3°C above normal, the average leukocyte count was 11,500, and the gall-bladder was palpable in forty-seven per cent of the cases (Temperature normal or subnormal in thirty-nine, 37 to 37.4 in twelve, 37.4 to 38 in fifteen, and above 38 in six. Leukocytes were normal or subnormal in eight, 7500 to 9000 in eleven, 9000 to 15,000 in seven. Gall-bladder palpable in thirty-four, or forty-seven per cent.)

In a group of nineteen cases in which the gall-bladder at operation showed definite areas of gangrene but no evidence of per-

foration the average temperature was 8°C above normal, the average leukocyte count 13,400, and gall-bladder was palpable in sixty-eight per cent of the cases (Temperatures normal or subnormal in six, from 37 to 37.4 in two, 37.4 to 38 in seven, and above 38 in four. Leukocytes were normal or subnormal in one, 7500 to 9000 in one, 9000 to 15,000 in eleven, and above 15,000 in six. The gall-bladder palpable in thirteen, or sixty-eight per cent.)

In a final group of fourteen cases in which the gall-bladder at operation showed gangrene and undoubted perforation with pericholecystic abscess (12) and general peritonitis (2) the average temperature was 7°C above normal, average leukocyte count was 14,100, and gall-bladder was palpable in seventy per cent of the cases (Temperatures normal or subnormal in two, from 37 to 37.4 in four, from 37.4 to 38 in five, above 38 in three. Leukocytes were normal or subnormal in none, 7500 to 9000 in two, 9000 to 15,000 in seven, and over 15,000 in five. Gall-bladder palpable in ten, or seventy per cent.)

Summarizing the series of 126 cases it may be said that the symptoms and physical signs varied greatly and of themselves often failed to give any definite information regarding the pathological process in the gall-bladder. A study of the temperatures, leukocytes, and size of the gall-bladder shows that in general there is a distinction which may be drawn between the cases of acute and subacute cholecystitis on the one hand and the cases of gangrene and gangrene with perforation on the other, and that this distinction lies in the higher temperatures, higher leukocyte counts, and higher percentage of palpable gall-bladders in the latter groups of cases. But in this series of cases there is little distinction clinically between the acute progressive and the subacute or subsiding cholecystitis and between the gangrenous and the gangrenous with perforation. It is, I think, worthy of note that in the 126 cases, thirty-three or twenty-six per cent showed gangrene of the gall-bladder and fourteen of these, or eleven per cent of the entire series showed perforation of the gall-bladder.

This has been my experience with 215 cases of acute cholecystitis. From the literature I might select a number of contributions to the subject, the authors of which have had an experience not unlike my own. For lack of time I quote but one and I select the contribution of Tourouff¹⁵ of the Mt Sinai Hospital. He studied pathologically the gall-bladders removed from seventy-five patients in whom at the time of operation the clinical symptoms and physical

signs were subsiding or minimal or had completely disappeared, and with the purpose of determining whether the pathological process in the gall-bladder corresponded with the clinical symptoms. In twenty-three of the seventy-five cases, the clinical symptoms were extremely mild at the time of operation and of these four or seventeen per cent had simple acute cholecystitis while eighteen or eighty per cent had more serious acute lesions of the gall-bladder. These included ten instances of gangrene, four of perforation, and five of pericholecystic abscess. In fifty-two of the seventy-five cases, the clinical symptoms had completely subsided prior to operation and of these twenty-nine, or fifty-six per cent, had simple acute cholecystitis and twenty-three or forty-four per cent had more serious acute lesions including empyema, gangrene, and perforation.

Such observations as I have related suggest the answer to my first proposition, namely, that in acute cholecystitis it often is not possible from the clinical symptoms and physical signs to determine the pathological course of the inflammatory process in the gall-bladder. The situation is somewhat similar to that in acute appendicitis, it differs from it largely in that the incidence of gangrene and perforation of the gall-bladder is not so high as the incidence of gangrene and perforation of the appendix, but that the incidence of these complications in acute cholecystitis is sufficiently high not to justify a surgical attitude toward the disease the reverse of that in acute appendicitis I shall hope to show later.

2 The second proposition has to do with the frequency of gangrene, perforation, and other serious complications which may develop in the course of the conservative treatment of acute cholecystitis and their importance as factors contributing to its mortality. No one denies that these complications occur, but the opinion is widespread that their occurrence is so rare that the mortality attending them is less than the mortality from operations performed in the acute stage of the disease. It is no doubt true that the experience of surgeons and surgical clinics varies considerably with respect to the incidence of gangrene and perforation of the gall-bladder in acute cholecystitis, that the incidence is always low is not the universal experience.

In my series of cases in Cincinnati, I found that among 150 cases of cholecystitis and cholelithiasis observed between 1925 and 1930, eighty-nine, or approximately fifty-nine per cent had acute cholecystitis and of these eighteen had at operation gangrene and per-

foration of the gall-bladder. This number of cases of gangrene and perforation represents twelve per cent of the total number of admissions for diseases of the gall-bladder and twenty per cent of acute cholecystitis. In my experience in the New York Hospital the past three and one-half years, I find that among 497 patients admitted with diseases of the gall-bladder, 126 had acute cholecystitis and of these thirty-three had gangrene or gangrene and perforation of the gall-bladder. This number of cases of gangrene and gangrene and perforation represents 66 per cent of the total number of admissions for disease of the gall-bladder, and twenty-six per cent of the cases of acute cholecystitis.

In the records of the Old New York Hospital between 1922 and 1932, I find eight hundred cases of disease of the gall-bladder of which 106 were certainly cases of acute cholecystitis and of which sixteen certainly and seven additional probably were cases of perforation of the gall-bladder. This number of cases of perforation represents 29 per cent of the total number of cases and twenty-one per cent of the cases of acute cholecystitis.

The studies of Eliason and McLaughlin,³ the experience of Gosset,⁴ Fifield,⁵ Fischer and Mensing,⁶ McWilliams,⁷ Alexander,⁸ Mitchell,⁹ Niemaier,¹⁰ Blalock,¹¹ Smith,¹² and others show that the incidence of gangrene and perforation in disease of the gall-bladder treated according to accepted methods is from two to three per cent. This seems an insignificant number in the practice of the individual physician or surgeon but when considered from the viewpoint of the very large number of individuals throughout the country treated for diseases of the gall-bladder, it is worthy of note.

More important, however, because it concerns particularly the subject we are discussing, is the frequency of gangrene and perforation of the gall-bladder in acute cholecystitis. In my studies of three series of cases (Cincinnati, Old New York Hospital, and New York Hospital) including about 320 cases of acute cholecystitis, the incidence of gangrene and perforation was twenty, twenty-one, and twenty-six per cent respectively. In the experience of Judd and Phillips,¹³ it was 134 per cent, Zininger,² 205 per cent, Morris Smith,¹² 224 per cent. These and similar statistical data present in the literature indicate that gangrene and perforation of the gall-bladder may be expected to occur in approximately twenty per cent of the cases of acute cholecystitis not promptly treated by surgery. It is a figure higher, I think, than is generally appreciated.

Not only does the inflammatory process in acute cholecystitis lead to gangrene and perforation of the gall-bladder under conservative treatment, but the mortality from these complications is high. In the Cincinnati series, the mortality following perforation of the gall-bladder was 187 per cent, in 800 cases in the Old New York Hospital it was 347 per cent, in the present series it was 153 per cent. A study of recent literature shows that in the experience of fourteen authors covering over 500 cases of perforation, the mortality varied between fifteen and sixty-five per cent and averaged forty-six per cent. Eliason and McLaughlin⁸ in a study of 555 cases of perforation, find a mortality which varied between eleven and fifty-eight per cent, but averages 47.6 per cent. This mortality, I find from a study of 35,000 cases of non-cancerous disease of the gall-bladder and biliary tract, represents ten per cent of the total mortality following surgical operations for this disease. In the experience of individual observers,¹⁴ the mortality from perforation alone accounts for twenty per cent of the total mortality in a general series of cases. This mortality is sufficiently great of itself, but there is, I think, an additional but unknown mortality chargeable to the too conservative treatment of acute cholecystitis. In the study of the 35,000 cases, I find that complications following operation such as peritonitis, hemorrhage, shock, ileus, etc., are responsible for approximately thirty-five per cent of the total mortality in operations upon the gall-bladder and bile ducts, and it seems perfectly clear that a part of this mortality is the result of difficulties and complications attending the surgical treatment of late manifestations of acute cholecystitis such as latent or long-standing extracholecystic abscess, liver abscess, adhesions, fistulae between gall-bladder and neighboring viscera, and inflammatory stricture of the common duct.

3 To reiterate, is the danger of operating in the acute stage of the disease before gangrene and perforation have occurred greater than the dangers of gangrene and perforation, the result of waiting for the so-called interval? There has been and still is a fairly widespread opinion that there is a definitely greater danger to the patient in operating in the acute stage of the disease, the presumed or real dangers being due to the failure of the patient to adjust himself to or establish resistance against the acute infection and to the oft-stated difficulties of the operation itself. The truth of the matter can be determined only by confining our studies to the disease we are

discussing—acute cholecystitis—and by a comparison of the results of the conservative method of treatment with the results in an equal number of cases in which a serious and deliberate effort has been made to operate before gangrene and perforation have occurred. Unfortunately available data in the literature to make such a comparison are meager. The mortality in acute cholecystitis based upon the experience of eight authors in 1275 cases varies between 47 and 225 per cent and averages 8.7 per cent. It should be pointed out, however, that this mortality is the result of the conservative policy rather than the result of a deliberately early attack upon the disease. The mortality in general following operations upon the gall-bladder and bile ducts based upon my study of 36,623 cases varied between 26 and 104 per cent and averaged 6.6 per cent. This, however, is an inclusive mortality for it includes the mortality in chronic cholecystitis and cholelithiasis which make up the larger number of cases in any series. This mortality, therefore, cannot be compared with the mortality of acute cholecystitis. I have made a diligent search of the literature and I fail to find careful accurate reports of any considerable series of cases strictly of acute cholecystitis treated by conservative methods with the results of this treatment, nor do I find any considerable series of cases of acute cholecystitis in which an early attack upon the disease has been deliberately planned and more or less consistently carried out. Nevertheless, the recent literature has supplied important information bearing on the proposition we are discussing. It has shown that if acute cholecystitis is studied by itself, its mortality following conservative methods of treatment is unexpectedly high. It has also shown that the dangerous lesions of the gall-bladder—gangrene and perforation—increase in frequency the longer the attack persists, and that the mortality increases greatly coincident with these complications.

What data I can find fail to establish the truth of the proposition that the danger of operating in the acute stage of acute cholecystitis is greater than the dangers of delay with the purpose of awaiting the disappearance of the acute manifestations of the disease. Rather they indicate that it is not sound. My own experience also does not support it. In my Cincinnati series, Zimninger showed that of thirty-five cases of acute cholecystitis subjected to immediate operation, the mortality was zero in twelve in which the attack was less than twenty-four hours in duration, 66 per cent in fifteen cases in which operation was per-

formed two to five days after the onset of the attack, and twenty-five per cent in eight cases in which operation was performed more than five days after the onset of the attack. In fifty-four cases in which a waiting policy was pursued before operation was performed, mortality was 55 per cent in eighteen cases in which the attack was less than one week in duration, and 83 per cent in thirty-six cases in which the attack was more than one week in duration. There is no evidence here that operation early in the attack is attended by a high mortality, on the contrary, operation in the early stages of acute cholecystitis in this series resulted in the lowest mortality.

My experience at the New York Hospital differs from that at Cincinnati in that since its opening in 1932 our attitude has been, whenever the patient's condition permitted, to deliberately operate early in the acute attack and with the purpose of lowering the mortality due to gangrene and perforation. As a result of this attitude practically seventy percent of the 126 cases of acute cholecystitis in this series were subjected to operation the day of admission to the hospital while thirty percent were observed forty-eight hours or more before operation was performed. Delay in operation, I find, was due either to time consumed in getting patients in favorable condition for operation or in differentiating between acute cholecystitis and other conditions with which it may be confused. Of the two reasons for delay, the former was by far the more frequent.

In the 126 cases deliberately subjected to early operation (cholecystectomy 113, cholecystostomy 12, drainage for peritonitis 1) there were five deaths, a mortality of 39 per cent. If I eliminate one case which does not bear upon the particular problem we are discussing—a child of nine with acute gangrenous typhoid cholecystitis and generalized peritonitis—there are 125 cases which come within our discussion with four deaths, a mortality of 3.2 per cent. Analyzed from the viewpoint of the extent of the disease, there were 112 cases of acute cholecystitis without demonstrable perforation of the gall-bladder and without extracholecystic abscess or other serious intra-abdominal complications. In this group of 112 cases there were two postoperative deaths, a mortality rate of 1.8 per cent. In thirteen cases with demonstrable perforation of the gall-bladder and with extracholecystic abscess (12) and generalized peritonitis (1), there were two deaths, a mortality rate of 15.3 per cent.

The experience gained from these two series of cases while, perhaps, not yet sufficiently large to warrant positive and dog-

matic statements, has convinced me that the dangers of operating in the acute stage of acute cholecystitis have been overestimated and are, in fact, less than the dangers of gangrene and perforation to which patients are subjected by waiting for the attack to subside. The mortality rate of 18 per cent in 112 cases deliberately subjected to early operation and actually operated upon before perforation of the gall-bladder had occurred is lower than the most favorable mortality rate in any general series of cases reported in the literature, and indicates that neither the supposed dangers due to failure of adjustment to infection nor to technical difficulties in the operative procedure outweigh the dangers of the waiting policy.

Summary

1 Frequently it is not possible from the clinical manifestations of acute cholecystitis accurately to visualize the course of the inflammatory process in the gall-bladder. Gangrene and perforation of the gall-bladder may exist or occur in the presence of subsiding symptoms. Delay in operation, therefore, without good reason, would seem unwise.

2 Gangrene or gangrene and perforation of the gall-bladder in acute cholecystitis occur too frequently and contribute too greatly to the mortality of the disease to be disregarded, especially since both the condition and the mortality largely are preventable. As has been shown the incidence of gangrene and perforation in acute cholecystitis is probably twenty percent and the mortality represents from ten to twenty per cent of the total mortality in noncancerous disease of the gall-bladder and bile ducts.

3 The dangers of operation in acute cholecystitis in any stage before perforation has occurred have been overemphasized and are distinctly less than the dangers of gangrene and perforation the result of a waiting policy. In 112 cases subjected to operation before perforation had occurred, the mortality was 18 per cent.

From these considerations, my attitude toward the treatment of acute cholecystitis is apparent. It is not the attitude that acute cholecystitis constitutes an emergency in the sense that every case must immediately be subjected to operation, but an attitude, the purpose of which is to lower the mortality in acute cholecystitis.

Not only does the inflammatory process in acute cholecystitis lead to gangrene and perforation of the gall-bladder under conservative treatment, but the mortality from these complications is high. In the Cincinnati series, the mortality following perforation of the gall-bladder was 187 per cent, in 800 cases in the Old New York Hospital it was 347 per cent, in the present series it was 153 per cent. A study of recent literature shows that in the experience of fourteen authors covering over 500 cases of perforation, the mortality varied between fifteen and sixty-five per cent and averaged forty-six per cent. Eliason and McLaughlin³ in a study of 555 cases of perforation, find a mortality which varied between eleven and fifty-eight per cent, but averages 47.6 per cent. This mortality, I find from a study of 35,000 cases of non-cancerous disease of the gall-bladder and biliary tract, represents ten per cent of the total mortality following surgical operations for this disease. In the experience of individual observers,¹⁴ the mortality from perforation alone accounts for twenty per cent of the total mortality in a general series of cases. This mortality is sufficiently great of itself, but there is, I think, an additional but unknown mortality chargeable to the too conservative treatment of acute cholecystitis. In the study of the 35,000 cases, I find that complications following operation such as peritonitis, hemorrhage, shock, ileus, etc., are responsible for approximately thirty-five per cent of the total mortality in operations upon the gall-bladder and bile ducts, and it seems perfectly clear that a part of this mortality is the result of difficulties and complications attending the surgical treatment of late manifestations of acute cholecystitis such as latent or long-standing extracholecystic abscess, liver abscess, adhesions, fistulae between gall-bladder and neighboring viscera, and inflammatory stricture of the common duct.

3 To reiterate, is the danger of operating in the acute stage of the disease before gangrene and perforation have occurred greater than the dangers of gangrene and perforation, the result of waiting for the so-called interval? There has been and still is a fairly widespread opinion that there is a definitely greater danger to the patient in operating in the acute stage of the disease, the presumed or real dangers being due to the failure of the patient to adjust himself to or establish resistance against the acute infection and to the oft-stated difficulties of the operation itself. The truth of the matter can be determined only by confining our studies to the disease we are

discussing—acute cholecystitis—and by a comparison of the results of the conservative method of treatment with the results in an equal number of cases in which a serious and deliberate effort has been made to operate before gangrene and perforation have occurred. Unfortunately available data in the literature to make such a comparison are meager. The mortality in acute cholecystitis based upon the experience of eight authors in 1275 cases varies between 47 and 225 per cent and averages 8.7 per cent. It should be pointed out, however, that this mortality is the result of the conservative policy rather than the result of a deliberately early attack upon the disease. The mortality in general following operations upon the gall-bladder and bile ducts based upon my study of 36,623 cases varied between 26 and 104 per cent and averaged 6.6 per cent. This, however, is an inclusive mortality for it includes the mortality in chronic cholecystitis and cholelithiasis which make up the larger number of cases in any series. This mortality, therefore, cannot be compared with the mortality of acute cholecystitis. I have made a diligent search of the literature and I fail to find careful accurate reports of any considerable series of cases strictly of acute cholecystitis treated by conservative methods with the results of this treatment, nor do I find any considerable series of cases of acute cholecystitis in which an early attack upon the disease has been deliberately planned and more or less consistently carried out. Nevertheless, the recent literature has supplied important information bearing on the proposition we are discussing. It has shown that if acute cholecystitis is studied by itself, its mortality following conservative methods of treatment is unexpectedly high. It has also shown that the dangerous lesions of the gall-bladder—gangrene and perforation—increase in frequency the longer the attack persists, and that the mortality increases greatly coincident with these complications.

What data I can find fail to establish the truth of the proposition that the danger of operating in the acute stage of acute cholecystitis is greater than the dangers of delay with the purpose of awaiting the disappearance of the acute manifestations of the disease. Rather they indicate that it is not sound. My own experience also does not support it. In my Cincinnati series, Zininger showed that of thirty-five cases of acute cholecystitis subjected to immediate operation, the mortality was zero in twelve in which the attack was less than twenty-four hours in duration, 6.6 per cent in fifteen cases in which operation was per-

flamed gall-bladder, and yet an inflammation that can be recovered from with relatively little observable damage the matter probably concerns the type of the infecting organism. With appropriate treatment, of the "deferred operation" type—omental adhesions are formed in a barrier about the inflamed gall-bladder and the exudates are absorbed. Operation upon some of these very acutely inflamed gall-bladders, at the end of the rest period, discloses a general peritoneal cavity which is not inflamed, edematous omental adhesions about the gall-bladder which are easily separated and when put aside disclose a gall-bladder still acutely inflamed, perhaps with minor perforations, and in the grossest aspect, with gangrenous spots, and containing pus and stones. But definitely a localized lesion, and localized by the patient's own forces of resistance which show, in his improved condition a general effect as beneficent as the local. The acutely inflamed gall-bladder, therefore, probably because of the nature of the infecting organisms usually involved, shows a very definite and decided ability to localize itself. This is not the invariable rule, but it is the rule.

The picture of the acutely inflamed appendix is quite different, gangrene and perforation are common, diffuse peritonitis is the rule, but the behavior of the peritoneum is different. In acute appendicitis, the peritonitis is diffuse, spreading, tends to become generalized, and the feeble barriers of inflammation erected by the defensive forces of the body are swept aside as swiftly as they are formed by the vicious onrush of an infection of such nature as to overwhelm the local forces of resistance. Here too the reason is probably largely the type of organism usually found in inflammation of the appendix. So the pathological march of events in the acutely inflamed appendix is toward a generalized peritonitis without adequate localization and without regression. This is not an invariable rule, but it is the rule.

Second, operability. In acutely inflamed gall-bladders the patient is in a condition which leaves much to be desired. Pain is frequently extreme, and in the cases of stone, is excruciating. Shock, due to excessive pain and rapidly spreading diffuse peritonitis, is a prominent feature, almost always present in very marked degree. With the onrush of peritoneal involvement the pulse is quickened, and very early in the severe infections, the temperature is well-elevated. But of all the features which are compelling in withholding immediate operation shock is the most striking and important. We must put shock upon shock

if we are to operate immediately. It can be done, but if there is a safe method to avoid it, it should not be done. I believe that delay will increase the safety of the operative procedure. But if delay is dangerous, then the dangers of delay must be put into the balance against the delay itself. We must all found our work upon our experience, and my experience brings me to the opinion that the danger of delay is less than the danger of an immediate operation. Contrast the picture of a patient suddenly seized with severe pain, rising temperature, mounting pulse, definitely shocked, and very sick, with the same patient after two weeks of rest, with sedation, ice bag, eventual bowel movements, and good nursing—now free from pain, afebrile, with normal pulse, with little or no rigidity, and no longer "sick"—and no surgeon would choose the former state as one preferable for operation. Remember that this outcome of deferred operation is not the invariable rule, but it is the rule.

Concerning statistics, I must say I find them positively cantankerous, but I shall do the best I can with them. I believe that the usually accepted method of treatment should be more definitely defined. It does not appear to me that a postponement of operation for a period of less than two weeks can be properly referred to, in the severe inflammations, as deferred operation. Further than this, I also consider that operation two-five days after the onset of symptoms constitutes early operation, if not immediate. I believe that Doctor Heuer's statistics are interesting, and are open to more than one interpretation. In one series, he reports twelve cases operated within twenty-four hours of the onset of the attack without a death, a mortality rate of zero cannot be much improved upon, but it is fair to assume, without cavilling, that these were decidedly the patients in the best condition of the series. The fifteen cases operated two-five days after onset with 66 percent mortality is surely creditable, for they, too, fall within my definition of cases operated upon during the period described as "more than five days" shows a mortality of twenty-five per cent a little higher than the usual average. The total mortality of these thirty-five cases, "subjected to immediate operation" is nearly ten per cent, also higher than the average, but it is fair to point out that this series of cases is small and percentages are likely to fluctuate sharply. Doctor Heuer's second series of 125 cases, showing a total mortality of 32 per cent and a selective mortality of 18 per cent can only be described

by every method we know, including early operation. It ignores as unfounded by experience the idea that the danger of operation in the acute stage of the disease is greater than that of gangrene and perforation, just as it does in acute appendicitis. It, therefore, accepts early operation as the safer method in the majority of cases. It appreciates, however, that acute cholecystitis is a disease which in general occurs in older age groups than does acute appendicitis and that in

a far higher proportion of cases hypertension, arteriosclerosis, and cardiac and renal diseases are present. It, therefore, recognizes that delay in order to improve the general condition of patients may be wiser in a certain number of cases than too hasty operation. This attitude is the reverse of the conservative attitude in that it deliberately intends early operation, but may withhold it when, in the judgment of the surgeon, it seems unwise. 525 E. 68 St.

Discussion

DR. ALEXANDER NICOLL, *New York City*—I shall agree at once with a part of the conclusions of Dr. Heuer, but in doing so I shall introduce what Teddy Roosevelt called a little "weasel word" here and there.

In his conclusions Doctor Heuer says in effect "From the clinical manifestations it is not possible to visualize the course of the inflammatory process in the gall-bladder." To this I agree. I would go further and say it is not even possible consistently to diagnose the extent or severity of the existing inflammation. But whether delay in operation is a factor in the production of gangrene and perforation must remain an academic discussion; it is not susceptible to proof. It would seem rather that the question is, shall we deal at once with gangrene and perforation *in the making*, and in the patient unfavorably disposed for operation, or shall we wait to operate upon this *same* gangrene and perforation after the patient's own bodily resistance has made the operative procedure a safer matter because of the improved general condition, and the absence of shock?

As to the proposition that gangrene or perforation of the gall-bladder in acute cholecystitis occur *too frequently* and contribute too greatly to the mortality of the disease—I agree. But that is a condition over which we have little control; the patient comes to us with these conditions already developed and we must treat him as well as we can. I have already indicated that I think we are not justified in believing that delay in operation is the

factor that determines the presence of these vicious complications. Perhaps early recognition of *any* disease of the gall-bladder is the correct solution, and operation upon the *non-acutely* inflamed gall-bladder is the way to avoid the acute gangrenous variety.

As to the dangers of operation in acute cholecystitis having been overemphasized here I cannot agree. The dangers are real, and because they are unnecessarily faced in the extremely acute stage, *must* be avoided.

I shall review very briefly two important phases of the gall-bladder situation, and because Doctor Heuer has indicated that he is inclined to draw inferences from the behavior of the appendix, I should like to point out one or two important differences. I speak under two headings: (1) Pathology and (2) Operability.

First, pathology. The acutely inflamed gall-bladder, filled with stones, containing pus, with gangrenous spots here and there in its walls—the precursors or perforations, perhaps only an hour or two ahead of actual perforation, and constituting potential or physiological perforations—this gall-bladder is rapidly surrounded by peritoneal reaction; the resulting peritonitis is diffuse to some extent, sometimes so widely diffuse as to be called a general peritonitis with the characteristics of peritoneal inflammation including the formation of exudate, serous, or thinly purulent, or plastic. But the peritonitis is usually of the variety that leads to eventual resolution; there is a factor that permits a rather widespread inflammation of the peritoneum about an in-

RELATIONSHIP OF MITRAL STENOSIS TO PULMONARY TUBERCULOSIS

LOUIS FAUGERES BISHOP, JR, M D and ANDREW BABEY, M D, *New York City*

Among the first to study the relationship of mitral disease and pulmonary tuberculosis was Rokitsky.¹ Writing in the middle of the last century, he observed that there was a remarkable, complete antagonism between the two diseases, based, he thought, on the hyperemia of the lungs which followed mitral disease. Very few physicians believe today that both diseases cannot exist in the same person, but many feel that such an occurrence is exceedingly rare. We undertook this study chiefly to discover how rare the combination may be.

To ascertain, if possible, how often these two lesions occurred together, we decided to review the figures at Bellevue Hospital, New York City.* The first set of records examined were those of the Tuberculosis Service. Over 650 autopsies were performed during 1922-1934 on this service. Only four instances of phthisis combined with mitral stenosis were found. This low incidence was misleading and we felt it was due to several factors, one of which was the great difficulty encountered in obtaining autopsies on this, as on any service, another factor to be considered was the great turnover because of the transfer to other institutions.

We next examined the general hospital records. In our search through the post-mortem records of the whole hospital from 1927 to 1934 inclusive, we attempted to include only those cases in which, first, the description of the valve defect very clearly indicated a notable mitral stenosis, no early, nor doubtful, cases were included.

The total number of autopsies was 9,091 during the period as stated, 1927-1934. Out of this number there were 140 cases of mitral stenosis and of these, six had proved pulmonary tuberculosis.

When we studied those with mitral stenosis who were forty-five years of age or younger (presumably the rheumatic group), we found fifty-six cases. Of these fifty-six, four individuals—aged twenty-seven, thirty-four, thirty-five, and

* Fourth Medical Division, Bellevue Hospital, New York City, Charles Nammack, M D, Director

as a brilliant achievement. To combine the two series and compute the correct percentage is beyond my feeble arithmetic.

I append a table of 215 cases from my service at Fordham Hospital without comment other than to say that they represent consecutive cases, as they occur in a large and busy municipal hospital, admitted mainly during the depression years when the attention of the typical hospital case was somewhat diverted from care of health to what they considered the more pressing needs of an economic nature. In this series, also, four of the deaths reported received spinal anesthesia and the cause of death, shortly after operation, was certified as shock. This somewhat vicious type of anesthesia clouds the picture. The entire list, however, is given without any revision.

I summarize them briefly thus

Total cases, 214 Total deaths 16, mortality

percentage 7.9 percent. Average time of operation after onset of symptoms, eleven days and varied from one to forty-two days. Seventy percent of the deaths occurred in the cases operated less than two weeks after onset of symptoms.

Acute Gall-bladders

Acute cholecystitis	110
Acute cholecystitis with cholelithiasis	90
Empyema of gall-bladder perforation of gall-bladder	14
Total	214
Age Varied from 19—77	Average, 43
19—30	41
31—50	125
Over 50	48
Cured or improved on discharge	198
Died	16

Cholecystectomy was done in 205 cases, cholecystotomies performed on nine, of which four died.

CALIFORNIA'S ABOUT-FACE ON HEALTH INSURANCE

"California Medical Association's Change of Attitude on Health Insurance," read the headline over an editorial published in a recent issue of *California and Western Medicine*.

When boiled down, the editorial said this:

Compared to expressions of sentiment and official action in 1934 and 1935, "a somewhat radical change of front concerning health insurance is quite apparent in the California Medical Association" (It will be remembered that the Association endorsed health insurance at a special session in 1935 when most of the other units of organized medicine were attempting to show the evils of bureaucratic medical schemes.)

California physicians still are deeply interested in hospitalization and medical service plans designed to improve the character and distribution of medical care, but "there is a widespread and accepted belief that because of the far-reaching social welfare factors involved, the solution of such medical relief problems as may be challenging both the profession and the laity, must come about through evolution and trial, and not by some of the revolutionary procedures advocated in the academic discussions of the subject."

At the recent Coronado meeting of the Association, the delegates expressed their interest in these matters but "basing judgment on the votes they gave, there can be little doubt on how goodly a majority of the delegates stood respecting matters of further experimentation with expensive and unsatisfactory surveys, which thus far have led to little more than a startling dissipation

of resources which the Association had slowly accumulated in previous years."

The Coronado delegates felt that the claims of advocates of sickness insurance were exaggerated and "that the remedies advocated were not adapted to achieving desirable ends for either the lay public or the medical profession."

Also, it was pointed out that there is no desire "to pursue, at the expense of the Association's members, further will-o'-the-wisp or other surveys" and that "there was a strong feeling of regret that the delegates who were members of the previous sessions of the House of Delegates should have embarked the Association upon expenditures far in excess of those first proposed and estimated by the salaried survey staff, running, indeed, into so massive a sum of the Association's funds as to be in excess of fifty thousand dollars."

There is a world of significance in the benediction

"Now, that so much has been spent, and there is so little to show therefrom, the realization of what is construed as hasty and ill-advised action becomes more and more apparent."

In other words, remarks the *Ohio State Medical Journal*, California has found its excursion to the "left," costly, unproductive and embarrassing. It may find out later that it has compromised itself to such an extent that only heroic action will prevent its previous policies from becoming boomerangs.

The California episode should serve as a warning to the other units of organized medicine.

INCREASING IMPORTANCE OF UNDULANT FEVER

JEROME KOGAN, M D, *Stamford*

The 1929 edition of Cecil's *Textbook of Medicine* describes this disease under the heading of Malta fever, and states that isolated cases sometimes occur in the United States "It is caused by *Micrococcus melitensis* and is usually spread by goat's milk" In parenthesis, the less common names are given as Mediterranean fever, Cyprus fever, undulant fever, etc The impression I gathered in my medical course was that this disease was unlikely to be encountered in my practice in New York State

Scarcely six years have elapsed since the issue of this textbook, and only three since the beginning of my active practice Yet today I would not dream of making a diagnosis of acute appendicitis or arthritis, or feel that I have exhausted the possibilities in an unusual case until I had definitely excluded undulant fever Clinically, the disease caused by *Bacillus abortus* is indistinguishable from Malta fever in man, and bacteriologically the similarity to *Micrococcus melitensis* is so great as to make one wonder if they are not identical

Undulant fever is readily transmitted to consumers of raw milk So prevalent has this infection become that few herds are entirely free from it If you live in New York State, it is almost certain that the milk on your table has come from an infected herd Thanks to pasteurization, the larger cities have considerable protection, but the extensive use of raw milk in smaller communities and farms has increased the number of cases to alarming proportions, and the vacationist may readily acquire the disease and return to contaminate the food supply in his household Thus this becomes a public health problem for the big city as well as for the village and farm

The disease sometimes presents a typical undulant fever However, many patients have little or no apparent fever Often some other clinical entity is stimulated, or no definite picture may be given Some patients are very sick, others may have only slight malaise The diagnosis cannot be made on physical examination alone, the disease must be kept

constantly in mind and possibilities tested for it A history of abortion in a herd is suggestive Definite diagnosis is made in the laboratory by agglutination tests for *B. abortus*, using the serum of blood collected as for a Wassermann examination The test may be made at the bedside or office by use of Huddleson antigen A drop of blood is mixed with a drop of the reagent on a slide and examined microscopically for agglutination A negative test does not exclude undulant fever, as the properties of the blood may not develop for some days Several cases, with positive findings only, are presented to show the variability in symptoms

CASE 1 G, male (Delaware County), age twenty-nine

Chief complaint Run down feeling for six weeks

Present history For six weeks has had poor appetite, tires easily, lassitude, occasionally slight fever

Examination Temperature 98.8—Rhinitis

Impression Possibly pulmonary tuberculosis

Course The patient eventually consulted a physician familiar with undulant fever, which was found on laboratory test

CASE 2 R. C, female (Delaware County), age fifty-four

Chief complaint Severe headache for one week

Past history Hypertension

Present illness Dizzy spells for one week with peculiar headache in frontal and occipital regions Painful eyeballs Slight nausea several days

Examination Temperature 100.5 Pulse one hundred Blood pressure 170/95 Moderate nasal and pharyngeal congestion and cervical adenitis

Diagnosis Upper respiratory infection

Course Three days later patient returned, complaining that she was no better A blood specimen was taken

Laboratory report Positive for undulant fever 1 320

CASE 3 F D, male (Otsego County), age fifty-two

Chief complaint General malaise two months

Present illness Had not felt well for two months A cold for about three weeks

forty-three—had pulmonary tuberculosis, an incidence of seven per cent for the younger group. Typical examples were as follows.

J B (A) had extensive cavernous tuberculosis with advanced mitral stenosis

O.K. (B) showed miliary tuberculosis with cavitation in the right upper, middle and lower lobes, in addition to a tight stenosis.

F E (C) showed miliary tuberculosis and ulcerative tuberculosis, there was also a very marked mitral stenosis.

We attempted to discover which lesion appeared first in these patients, but the clinical records were not complete, for these younger patients died from one to seven days after admission to the hospital.

Discussion

These figures and data suggest a more critical estimate of the work of the early writers. In the first place, mitral stenosis and pulmonary tuberculosis can and do occur together, and are by no means rare according to our figures. Moreover, it is our belief that clinically the two are even more common than shown by this pathological study. We feel that the possibility of the occurrence of pulmonary tuberculosis should be entertained and investigated in every blood-spitting "mitral case" as well as in others. We also find it impossible to subscribe to the view that pulmonary tuberculosis is less virulent, more local, and runs a chronic course with a tendency to heal, when mitral stenosis is present. It has been cited frequently that when a tight stenosis existed, the chances of recovery were greater. This was difficult to confirm, as the persons who were studied died soon after admission of an extensive and destructive type of tuberculosis, despite a very extreme degree of mitral stenosis. Perhaps one reason why we do not see the combination of mitral stenosis and phthisis more frequently is because many of these patients are either told they have a murmur or heart disease. For that reason they moderate their activity because they soon find out that exertion and exercise disturb the heart rate or breathing. Automatically, they adopt a modified tuberculosis regime, or it is enforced by those responsible for their care.

Conclusion

A review of the relationship of mitral stenosis and pulmonary tuberculosis at Bellevue Hospital shows that this association is by no means rare.

VASOMOTOR AND ATROPHIC RHINITIS

Relation to Body Fluids and Sodium Metabolism

SAMUEL KAPLAN, M D, *Brooklyn*

Department of Otolaryngology, Long Island College Hospital

By far the most baffling of clinical entities with which the rhinologist is confronted are vasomotor rhinitis and atrophic rhinitis. The vast amount of discussion that the first of these has brought about is evidence of the lack of proper interpretation. As for atrophic rhinitis, most rhinologists feel that it is a hopeless chronic affliction and treat it palliatively. Those with more imagination experiment with endocrine therapy but in an uncontrolled hit or miss manner.

The two conditions, peculiarly enough, seem to result from a common cause, namely, abnormal fluid content of the tissues. Nor is this abnormality confined to the nasal lining. Even casual study will show that symptoms attributable to tissue fluid abnormality are present in other parts of the body.

If one were to graphically chart the color and consistency of nasal mucosae of patients free of demonstrable infection and normal hemoglobin, he would find that they make a curve similar to a curve of growth variation, or variations in weight, baso-metabolic rates, etc. The point is that the nasal mucosa shows a physiologic variation. At one extreme end of the curve there would be a small number of dry, red, hyposecretory nasal membranes, at the other, a small number of pale edematous membranes, between these extremes, varying degrees of pink to red which we arbitrarily call normal. It is the cases at each extreme which vary so much from the physiological that they are regarded as pathological.

The outstanding difference being the variation in the amount of fluid in the tissue, it occurred to the writer that a clear comprehension of the physiology and chemistry of tissue fluids would perhaps open the way to a clearer interpretation of the troublesome clinical entities. Furthermore, the observation that there is a gradual variation in individuals with the extremes approaching a pathological status suggested that the phenomenon may ultimately be found to depend on one particular factor somehow related to the

complex metabolism of body fluids and their constituents.

It is beyond the scope of this paper to go into the intricate details of the physical chemistry of the fluids of the body. A perusal of the older and modern literature on the subject shows that a tremendous amount of work has been done, and that very illuminating facts have been discovered. The writer will only briefly summarize some of these and trust that aroused interest will lead to further study of the references given.

The principal body fluids are blood serum, lymph, interstitial fluid which includes intercellular fluid, and intracellular fluid. The lymph need not be considered here as it is only a specialized mechanism for the absorption from the interstitial fluid of colloid material which is not diffusible through the other avenues of interchange. The blood serum, interstitial, and intracellular fluids are those open the way to a clearer interpretation of constituents of these fluids has been thoroughly investigated and we shall point out the important factors.

It was shown by Starling¹ that capillaries are not only capable of filtering fluid into the interstitial environment by virtue of the hydrostatic pressure, but also of reabsorbing fluid by virtue of the colloid osmotic pressure of the blood serum. Krogh² showed that the hydrostatic pressure in capillaries have a gradient, decreasing as they approach the venous. The reabsorption which is due to colloid osmotic pressure is opposed by the hydrostatic pressure and therefore will be inversely proportional to it. Krogh also showed³ that the permeability of the capillaries can be altered through nervous control and that they possess an independent power of contractility.

The nature of interstitial fluid has merited considerable discussion. It seems, however, finally agreed that it is an ultrafiltrate and not a secretory product.⁴ Since interstitial fluid is an ultrafiltrate of diffusible elements in blood serum, one would expect that its electrolyte pattern

with headache, general body aches, morning cough, and slight loss of weight

Examination Temperature 99.2 Pharyngitis Coarse rales and wheezing breath sounds bilaterally

Impression Tuberculosis Rule out undulant fever

Laboratory report Positive for undulant fever 1 80

CASE 4 V H, male (Schoharie County), age sixteen

Chief complaint Pain in left elbow

Present illness Pain in left elbow and left knee for two weeks Wringing sweats at night, sleepiness, tires easily Slight cough

Examination Temperature 98.7 Pulse ninety Pale Rhinitis

Impression Possible undulant fever History cattle abortion

Laboratory report Positive 1 2500

CASE 5 M S, male (Delaware County), age nine

Chief complaint Abdominal distention

Past History Appendicitis four years ago, treated medically

Present illness For three days patient has had no bowel movements and marked distention After two more days of observation by the family physician, the boy was sent to the hospital where I saw him in con-

sultation Temperature 102 Pulse ninety-eight. White blood count 6550 Marked distention. Patient states he does not feel sick My impression was acute appendicitis, and suggested further observation All this time (five days) there had been no bowel movement.

Course After several attempts, enemas became productive, and the distention subsided Temperature continued to fluctuate between 99 and 104 The temperature curve suggested undulant fever

Laboratory report Positive 1 640

CASE 6 J S, female (Delaware County), age eleven and one-half

Chief complaint Abdominal pain

Present illness The family physician obtained the following history Chills and fever shortly after breakfast. Abdominal pain, intermittent, progressively worse. He found tenderness in both lower quadrants and in the loin on the right. Rectal tenderness on the right Temperature 102 Pulse 120 White count 11,500 Bedside test for undulant fever negative. He removed the appendix, with the author assisting

Course The temperature continued high and the patient's appearance seemed unusual The test for undulant fever was repeated and found strongly positive.

ROOSEVELT AVE.

PUNCH-DRUNK BOXERS AND FOOTBALL PLAYERS

When Gene Tunney noticed the first signs of being punch-drunk, he vowed to leave the prize ring That he was a wise young man is indicated by the recent study made by Edward L Carroll, Jr, Pittsburgh psychiatrist and boxing enthusiast who started his study of this condition while a medical student. His evidence points to many tiny ruptures of the blood vessels of the brain as being responsible for punch-drunkness

Other sports in which head blows are numerous, as in football, can cause a similar condition Attention, concentration, and memory suffer permanently in a full-grown

case of punch-drunkness, the victim is often unusually talkative, but rambles and repeats himself, his speech may show some impediments, eye become slightly glazed, walk unsteady, voice thick.

The punch-drunk person seldom realizes his condition, and is inclined to be offensive when accused of it. If your boy plays football, he should wear a well-padded head gear during every second of practice and play Those tiny ruptures seem to be permanent for the punch-drunk athlete usually goes from bad to worse.

—*Health Digest*

ADD ACCIDENTAL DISCOVERIES

An anecdote in a new book on "Food, Fitness and Figure" refers to Eijkmann's discovery of the cause of beriberi The doctor, stationed in a prison camp in Java, hired a native boy to feed his pigeons, and from time to time gave him money to buy rice for this purpose. The boy, however, got the steward of the camp to give him the

rice, and put the money in his pocket. This rice was polished, and the birds, like the inmates of the camp, soon developed beriberi When the disease among the birds was at its height, the steward went away on leave, and the boy was obliged to buy rice in the market. This happened to be unmilled and when it was fed most of the birds recovered.

loids retained in the serum, a greater amount of potassium and calcium will be bound in an undissociable form perhaps depleting the interstitial fluid of these elements of which it normally has but small quantities. The base in the interstitial fluid, which is normally ninety per cent sodium, will increase to be almost entirely composed of sodium. The exact reverse of this phenomenon can occur with excessive excretion of sodium in which a general loss of fluids will result. Both these states can be produced by a hyperactivity or a hypoactivity of the adrenal cortex hormone.

A few more facts with regard to inorganic environment of tissue will help clarify the writer's theory. Biederman, Ringer, Loeb, and others as quoted by Robertson¹⁴ have shown that solutions of sodium salts caused irritation of muscular and nerve tissue. Solutions of pure salts act as protoplasmic poisons. For physiologic purposes, solutions of sodium salts must contain traces of calcium and potassium. Loeb noted that addition of calcium and potassium salts to sodium counteracted the irritating effects, and determined a ratio of these elements which were of optimal benefit for physiological function.

In experiments on animal physiology, Loeb¹⁵ discovered an important phenomenon. Using fertilized eggs of the marine fish *Fundulus* he found that the cell membrane became permeable when placed in 3 M Sol of Na Cl. However, when 2 c.c. of 10/8 M Ca Cl 2 were added, to fifty c.c. of the above solution the membranes remained impermeable.

To summarize thus far Body fluids contain electrolytic patterns determined by the electrolytic pattern of blood serum. The latter is dependent on the control of its sodium which seems to be determined by a hormone secreted by the adrenal cortex. Increases in the amount of sodium leads to fluid retention or edema and to depletion of traces of calcium and potassium in the interstitial fluid which is the inorganic environment of the cells being unbalanced physiologically has an irritating effect on the cells and alters the cell membranes so that they become permeable to foreign substances.

The above observations lend themselves very readily to clinical interpretation of vasomotor rhinitis and atrophic rhinitis. The two conditions are extremes in physiologic variation of fluid and elec-

trolyte balance. Especially do these observations help explain the apparent allergic status associated with vasomotor rhinitis. The writer firmly believes that vasomotor rhinitis in itself is not an allergic state, but is the result of faulty fluid and sodium balance. In this state abnormal permeability is often present and the patient may become sensitized to allergens which from time to time penetrate the permeable membranes.

Similarly, the writer believes that atrophic rhinitis is primarily not an infectious state, but due to fluid depletion and cell atrophy, the protective secretory power is hindered with the result that infection may secondarily set in.

When attempting hormonal therapy, one is beset by great difficulties. Not always is the hormone available in proven potent states, and in the hyperactive states anti-hormonal agents are seldom known. It is for this reason that chemical alterations rather than endocrine were employed in the clinical experiment.

The aim in the cases of vasomotor rhinitis was to deplete sodium and to increase potassium and calcium in a dissociated form by the administration of acidifying agents. A number of patients showing marked pale edematous nasal mucosae were chosen. A capsule was prepared containing the acid salt ammonium chloride five grains, potassium chloride two grains, and calcium gluconate five grains. The dose consisted of one capsule three times daily and quickly increased to three or four capsules three times daily. Ingestion of salt was limited. The results were in several cases remarkable and in all cases satisfactory. Not only were the subjective symptoms of sneezing and obstruction eliminated, but objectively the nasal mucosa lost the pale edema and became pink. In one case the nasal lining approached the dry red hyposecretory condition. When medication was withdrawn, the condition gradually returned to the pale edematous state.

Several patients with dry "atrophic" nasal membranes were put on forced sodium chloride ingestion—from one to three teaspoons daily. There was a marked improvement in secretion. One case of ozena was treated similarly. There was some improvement inasmuch as the crusts became moist and separated easily.

would be similar. This, however, is not the case. The sodium, potassium, and calcium content differs considerably. The reason for this is that in the serum some of these ions are bound with proteins and lipoids forming an undiffusible base. Applying the Gibbs-Donnan principle⁴ of osmosis between diffusible and non-diffusible elements, the difference in electrolyte pattern can be explained. Since the potassium ion has a greater affinity for protein, less of it will diffuse and therefore less of it will appear in the interstitial fluid. The ratio of K to Na in transudates will be smaller than in serum.⁵ However, if serum is acidified there will be a dissociation of combined potassium and the discrepancy will diminish.⁶ The increase of ultrafiltrability of calcium in acidified serum can be explained in the same way.⁷

Interstitial fluid, although an ultrafiltrate of blood serum, consists chiefly of chloride and bicarbonate of sodium. There is a tendency for accumulation of interstitial fluid when a greater amount of sodium is present, hence producing edema.⁸

From many analyses it seems that the intracellular fluid of the body contains practically no sodium but has potassium as the entire base. The surrounding interstitial fluid, on the other hand, contains mostly sodium with only slight traces of potassium and calcium. The sodium makes up about ninety per cent of its base.⁹ The separation of potassium and sodium in different compartments of an osmotic system, has the advantage of preserving the integrity of the cell against inroads of the external environment. If sodium formed the base for both the intracellular and interstitial fluid, its passage back and forth across the cell membrane, with every slight alteration in osmotic equilibrium, would lead to serious upset to the glycogen, proteins, and lipoids bound to the base. However, the arrangement being as it is, the delay in interchange allows time for other agents to re-establish osmotic equilibrium.

It is obvious that while intracellular and interstitial fluids have different electrolyte patterns from blood serum, they are, nevertheless, derived from it. Furthermore any change in the composition of the serum will be reflected in these other fluids. However the pattern of serum

composition appears to be rigidly guarded. Slight physiologic variations are present, but at all times some mechanism is at work to readjust the balance. This mechanism is the excretory function of the kidneys.

The kidneys with uncanny judgment throw out only those substances which are in excess. In excreting waste products, they guard the intricate details of the electrolyte pattern of the serum and therefore of all the body fluids. Total base and especially sodium receive considerable attention. Nor is any effort seen in substituting other electrolytes for sodium (in cases of abnormal depletion of this element) in order to preserve the electrolyte osmotic pressure. As shown by Loeb¹⁰ and Höglér¹¹ even when sodium is depleted, ingested potassium salts continue to be excreted completely and rapidly.

The mysterious agent that stands guard over serum sodium seems to be of hormonal nature. This hormone seems to originate in the adrenal cortex as demonstrated by Harrop and Weinstein¹² and Loeb.¹³ Harrop and Weinstein found that adrenalectomized dogs could be kept alive by administration of adrenal cortex extract. When the extract was withdrawn there was a marked drop in blood sodium and the animals died with no other demonstrable pathology on autopsy. Robert F. Loeb in a study of electrolyte balance in adrenalectomized dogs obtained similar data. There was a marked loss of sodium from the blood which appeared in the urine. The blood also showed a retention of nonprotein nitrogen and potassium. In his conclusions he suggests the possibility of the adrenal cortex being the regulating mechanism of sodium metabolism in a similar manner to the parathyroids regulating calcium and phosphorous metabolism.

Thus it becomes apparent that any disturbance in sodium metabolism or in sodium excretion will be reflected throughout all the body fluids and will alter the inorganic environment of the tissues. If the total amount of sodium in the body is kept on a high level, there will also be water retention causing edema or increased fluid in the interstitial environment. Furthermore changes in osmotic pressure will result unless the blood serum retains more colloids. With more col-

loids retained in the serum, a greater amount of potassium and calcium will be bound in an undissociable form perhaps depleting the interstitial fluid of these elements of which it normally has but small quantities. The base in the interstitial fluid, which is normally ninety per cent sodium, will increase to be almost entirely composed of sodium. The exact reverse of this phenomenon can occur with excessive excretion of sodium in which a general loss of fluids will result. Both these states can be produced by a hyperactivity or a hypoactivity of the adrenal cortex hormone.

A few more facts with regard to inorganic environment of tissue will help clarify the writer's theory. Biederman, Ringer, Loeb, and others as quoted by Robertson¹⁴ have shown that solutions of sodium salts caused irritation of muscular and nerve tissue. Solutions of pure salts act as protoplasmic poisons. For physiologic purposes, solutions of sodium salts must contain traces of calcium and potassium. Loeb noted that addition of calcium and potassium salts to sodium counteracted the irritating effects, and determined a ratio of these elements which were of optimal benefit for physiological function.

In experiments on animal physiology, Loeb¹⁵ discovered an important phenomenon. Using fertilized eggs of the marine fish *Fundulus* he found that the cell membrane became permeable when placed in 3 M Sol of Na Cl. However, when 2 c.c. of 10/8 M Ca Cl 2 were added, to fifty c.c. of the above solution the membranes remained impermeable.

To summarize thus far. Body fluids contain electrolytic patterns determined by the electrolytic pattern of blood serum. The latter is dependent on the control of its sodium which seems to be determined by a hormone secreted by the adrenal cortex. Increases in the amount of sodium leads to fluid retention or edema and to depletion of traces of calcium and potassium in the interstitial fluid which is the inorganic environment of the cells being unbalanced physiologically has an irritating effect on the cells and alters the cell membranes so that they become permeable to foreign substances.

The above observations lend themselves very readily to clinical interpretation of vasomotor rhinitis and atrophic rhinitis. The two conditions are extremes in physiologic variation of fluid and elec-

trolyte balance. Especially do these observations help explain the apparent allergic status associated with vasomotor rhinitis. The writer firmly believes that vasomotor rhinitis in itself is not an allergic state, but is the result of faulty fluid and sodium balance. In this state abnormal permeability is often present and the patient may become sensitized to allergens which from time to time penetrate the permeable membranes.

Similarly, the writer believes that atrophic rhinitis is primarily not an infectious state, but due to fluid depletion and cell atrophy, the protective secretory power is hindered with the result that infection may secondarily set in.

When attempting hormonal therapy, one is beset by great difficulties. Not always is the hormone available in proven potent states, and in the hyperactive states anti-hormonal agents are seldom known. too late. I had learned to hate him. And I really had nowhere to go. I had much freedom in the day time and I used it all out. The child didn't bother me much. What I could never get, in those early years, when the youngster was still a baby, was the pleasure of going out together with my husband. I longed for that. Of course, by and by I forgot it. On a Sunday, yes, but it was with the baby and motherhood weighed heavily upon me. I wanted to be a girl again and forget the child. To be like two lovers, my husband and myself, and laughing, dancing, spend our time lightly! No, this was not to be. And this unfulfilled desire was like the first crack in one of my earthen pots—ominous, sure to go on until it will break it completely. And it did. To separate? To divorce? I cannot do it. I am too much of a coward. And I could not face my family. Let him start it, then I'll only be too glad. Why I do not take a lover? Oh, doctor, how can you say that? I would never enjoy it. It would only free my husband. Why don't you make this suggestion to him? How I wish he would follow it! This means that I still love him? Oh, you make me laugh! Oh, you have never met him? I'll send him to you, you know, on one of his bad days. You ought to see him. Sometimes I actually think he'll go mad. Of course, I know, Doctor, you'll not give him the advice you give me. But he needs you. He is not crazy yet, but he is no longer sane."

And now he has come. He had an awful night, he said. "One of those nights that made him doubt whether his mind would survive," he added.

"I see the abyss in front of me. I am falling into it, doctor. It is coming! I'll be alive, but the chief things in me will be dead. I get such funny notions, such weird thoughts."

And he told me about last night's quarrel.

He had not had any sex relations for months. They always slept separately. Last evening he happened to be home and she seemed to be somewhat accessible. But later she demurred. She was adamant. And she taunted him with all kinds of humiliating words. He was a sexual weakling anyhow. And who would believe him that he had no other woman? Would he stay so long without intercourse? That she did not permit it was no excuse. A real man would take her by force. And she invited him to do it, she dared him use violence.

He could not sleep the whole night. He walked the floor, he cried into the pillow until five in the morning, while she did not mind it and snored serenely. At six his

alarm-clock woke him up and he went to work. But at ten in the morning he had to quit—and he came to my office.

It was too late to improve the damage done. The rent was too deep and painful and beyond repair.

Perhaps this marriage was doomed before it was consummated. But he had committed the mortal sin of neglecting her for the benefit of his movement or cause in those first sensitive years. No man, no woman can forgive lack of attention, nobody wants to be superseded by some other interest. Now they had both harmed each other—she in a more venomous way, he in a more polite form—and they had acquired the habit of biting and scratching. War!

As he was more the victim and his mental health was really threatened, it was necessary to make him understand, not only his mistakes, but her tactics as well, and to teach him how to take her attitude philosophically. Also, if he did not think that the lack of intercourse was damaging to him, which he had confessed he feared—as a result of his reading all sorts of exaggerated theories—he would be quieter. If he were less eager to possess her bodily and more attentive to her from another standpoint, she might begin to desire a contact. Of course, he needed the sexual satisfaction, but he could stand its absence better if he were not afraid of imaginary effects. It was probable that, if conditions should not change, he would, sooner or later, find an outlet in some other woman's company. But it was not my business to suggest anything along those lines.

After all, no one could be absolutely certain that even his wife might make some concessions and that a *modus vivendi* might be re-established, if he were able to appear unconcerned at her big attacks or little pricks and if he could really relinquish many of his activities. The problem of caring for the child in the evening should be solved. For a small sum a person might be left with the boy once in a while and the patient might try to be nice to his wife in a new fashion or rather going back to their wooing period. He ought to make an attempt to be somewhat less serious, less oldish, and more prankish. If possible, he should enlighten his wife in his ideas, interest her in his public work and make her share it, so that she should become his partner and companion.

He would have to inform me frequently about his progress and come for encouraging conversations and perhaps for sources of inspiration to be tapped on his road of conquest of his own wife.

In these cases, as in the first group, symptoms reappeared promptly upon withdrawal of the medication

Summary

Notice is taken that both vasomotor rhinitis and atrophic rhinitis are extremes approaching the pathologic in a normal physiological variation in fluid content of tissues. An attempt is made to explain this variation on electrolyte control, especially of sodium. Evidence is cited

for the adrenal cortex hormone being the regulator of body sodium. Evidence is also cited on the effect of sodium on cell membranes, altering their permeability. This fact is employed to interpret the allergic states often associated with vasomotor rhinitis. Therapy with the aim of forcing chemical change in the electrolyte pattern of body fluids on cases of vasomotor and atrophic rhinitis appear to support the view that fluid and sodium balance is the underlying cause for these clinical entities. BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., New York City

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Bedroom Conflicts

"Doctor, my mind is ebbing. I feel it sinking. I go down, down. I am afraid. Please do something!"

A man of thirty-five was speaking. He was bright, handsome, physically healthy, married ten years to a pretty woman, they had a child.

I used to see her often, coming with her boy for small ailments. At those occasions she would pour out her heart, filled with hatred for the husband.

"Not that I can blame him for anything," she would say. "He is kind and considerate and always makes a living. He is the perfect man. He loves me—and that is the worst part of the entire situation. I cannot stand his attentions. You know, ours was a love marriage. But I gradually found out that I really never cared for him. How I would like him to be faithless! But—no! Nothing can chase him into anybody else's arms. I have done everything to enrage him or—to make him crazy. Everything that I had heard might cause insanity. I have been fiendish. But so far it was in vain. Now, it seems to me, I have found the remedy. I let him make love to me—

I don't repel him, that is at first. I don't. But when he is all heated up, I don't allow him to come near me. Then I feel good. He is mad, mad, and I laugh inwardly. I fear him too. I fear he might strike me, although I should like that to happen. I almost invite him to do it, I provoke him. He, however, remains the same gentleman even then. Finally, I am the one who is licked. If he'd at least threaten me—I'd have an excuse to go crying before his friends, and accuse him. Yes, he has some reputation in his circle. He is quite a leader among his people and very active. What do I say, active? He is sincere and devoted. He'd give his life. There's the rub. That's what I can't stand. I can't make it out, but somehow that's the real cause of the trouble. The whole thing started with this—with his spending his evenings at meetings and in committee work. He enjoyed it and gave himself to it while I felt that I got only the crumbs. When I finally protested and said that I too wanted to go somewhere in the evening, he immediately made arrangements to stay at home with the child on such nights. But it was

too late. I had learned to hate him. And I really had nowhere to go. I had much freedom in the day time and I used it all out. The child didn't bother me much. What I could never get, in those early years, when the youngster was still a baby, was the pleasure of going out together with my husband. I longed for that. Of course, bye and bye I forgot it. Nothing can chase him into anybody else's arms. I have done everything to enrage him or—to make him crazy. Everything that I had heard might cause insanity. I have been fiendish. But so far it was in vain. Now, it seems to me, I have found the remedy. I let him make love to me—

I don't repel him, that is at first I don't. But when he is all heated up, I don't allow him to come near me. Then I feel good. He is mad, mad, and I laugh inwardly. I fear him too. I fear he might strike me, although I should like that to happen. I almost invite him to do it, I provoke him. He, however, remains the same gentleman even then. Finally, I am the one who is licked. If he'd at least threaten me—I'd have an excuse to go crying before his friends, and accuse him. Yes, he has some reputation in his circle. He is quite a leader among his people and very active. What do I say, active? He is sincere and devoted. He'd give his life. There's the rub. That's what I can't stand. I can't make it out, but somehow that's the real cause of the trouble. The whole thing started with this—with his spending his evenings at meetings and in committee work. He enjoyed it and gave himself to it, while I felt that I got only the crumbs. When I finally protested and said that I too wanted to go somewhere in the evening, he immediately made arrangements to stay at home with the child on such nights. But it was

too late. I had learned to hate him. And I really had nowhere to go. I had much freedom in the day time and I used it all out. The child didn't bother me much. What I could never get, in those early years, when the youngster was still a baby, was the pleasure of going out together with my husband. I longed for that. Of course, bye and bye I forgot it. On a Sunday, yes, but it was with the baby and motherhood weighed heavily upon me. I wanted to be a girl again and forget the child. To be like two lovers, my husband and myself, and laughing, dancing, spend our time lightly! No, this was not to be. And this unfulfilled desire was like the first crack in one of my earthen pots—ominous, sure to go on until it will break it completely. And it did. To separate? To divorce? I cannot do it. I am too much of a coward. And I could not face my family. Let him start it, then I'll only be too glad. Why I do not take a lover? Oh, doctor, how can you say that? I would never enjoy it. It would only free my husband. Why don't you make this suggestion to him? How I wish he would follow it! This means that I still love him? Oh, you make me laugh! Oh, you have never met him? I'll send him to you, you know, on one of his bad days. You ought to see him. Sometimes I actually think he'll go mad. Of course, I know, Doctor, you'll not give him the advice you give me. But he needs you. He is not crazy yet, but he is no longer sane."

And now he has come. He had an awful night, he said. "One of those nights that made him doubt whether his mind would survive," he added.

"I see the abyss in front of me. I am falling into it, doctor. It is coming! I'll be alive, but the chief things in me will be dead. I get such funny notions, such weird thoughts."

And he told me about last night's quarrel.

He had not had any sex relations for months. They always slept separately. Last evening he happened to be home and she seemed to be somewhat accessible. But later she demurred. She was adamant. And she taunted him with all kinds of humiliating words. He was a sexual weakling anyhow. And who would believe him that he had no other woman? Would he stay so long without intercourse? That she did not permit it was no excuse. A real man would take her by force. And she invited him to do it, she dared him use violence.

He could not sleep the whole night. He walked the floor, he cried into the pillow until five in the morning, while she did not mind it and snored serenely. At six his

alarm-clock woke him up and he went to work. But at ten in the morning he had to quit—and he came to my office.

It was too late to improve the damage done. The rent was too deep and painful and beyond repair.

Perhaps this marriage was doomed before it was consummated. But he had committed the mortal sin of neglecting her for the benefit of his movement or cause in those first sensitive years. No man, no woman can forgive lack of attention, nobody wants to be superseded by some other interest. Now they had both harmed each other—she in a more venomous way, he in a more polite form—and they had acquired the habit of biting and scratching. War!

As he was more the victim and his mental health was really threatened, it was necessary to make him understand, not only his mistakes, but her tactics as well, and to teach him how to take her attitude philosophically. Also, if he did not think that the lack of intercourse was damaging to him, which he had confessed he feared—as a result of his reading all sorts of exaggerated theories—he would be quieter. If he were less eager to possess her bodily and more attentive to her from another standpoint, she might begin to desire a contact. Of course, he needed the sexual satisfaction, but he could stand its absence better if he were not afraid of imaginary effects. It was probable that, if conditions should not change, he would, sooner or later, find an outlet in some other woman's company. But it was not my business to suggest anything along those lines.

After all, no one could be absolutely certain that even his wife might make some concessions and that a *modus vivendi* might be re-established, if he were able to appear unconcerned at her big attacks or little pricks and if he could really relinquish many of his activities. The problem of caring for the child in the evening should be solved. For a small sum a person might be left with the boy once in a while and the patient might try to be nice to his wife in a new fashion or rather going back to their wooing period. He ought to make an attempt to be somewhat less serious, less oldish, and more prankish. If possible, he should enlighten his wife in his ideas, interest her in his public work and make her share it, so that she should become his partner and companion.

He would have to inform me frequently about his progress and come for encouraging conversations and perhaps for sources of inspiration to be tapped on his road of conquest of his own wife.

Endorsement of Foreign Licenses

Section 1259 of the Medical Practice Act of New York contains a provision that "the commissioner of education may in his discretion on the approval of the board of regents endorse a license or diploma of a physician from another state or country," provided that all professional qualifications have been met and if, after ten years of practice, the applicant has attained a position of authority in his profession

No other state in the union permits one to practice medicine unless he shall have passed the prescribed examinations given by the board of medical examiners. Exceptions are made only where reciprocal relations have been established between the separate states and in the event of physicians employed in the Federal services. New York State, however, which contains the port of entry for the largest number of immigrants, has been more lenient toward the newly arrived professional men, and has facilitated their entry into the active practice of medicine.

With the sudden influx of physicians and other members of the allied professions which was occasioned by the political and social upheaval in Germany, there developed a strong sympathy among the practicing physicians of our State to aid these refugees and do all in our power to help them get a fresh start. Had these

immigrant physicians distributed themselves evenly throughout the country their number would not have been noticed and they would have made welcome additions to the several communities in which they would have settled. The requirements for obtaining a license to practice medicine elsewhere than in New York, where it could be granted by an endorsement of credentials, kept the greatest proportion of them here. This has led our Board of Regents to pass the ruling that upon applications filed after October 15, 1936, no license issued in a foreign country will be endorsed until the applicant shall have passed the licensing examinations.

This resolution will receive the wholehearted endorsement of the profession of this State. Many rumors have reached the ears of the officials of our Society concerning abuses which have arisen in connection with the licensing by endorsement. The practice of medicine in this State should be kept at the high level it has always maintained and no opportunity should be given for the lowering of these standards.

Valuable Information

The survey of consumer purchases that the U S Bureau of Labor Statistics is conducting in conjunction with the Federal Bureau of Home Economics should

throw a revealing light on the relationship of medical expenses to family income and expenditures. Instead of condensing the figures obtained into a deceptive average, the investigators will analyze them according to geography, income, and occupation. In every regional group under consideration, for example, subclassifications will be made into thirteen income brackets, eleven types of family composition, and seven occupational divisions. This will give a far truer picture of the economic aspects of medical care for the general public than spurious averages which embrace unemployed and millionaires.

Business—large and small—is supporting the survey because of the invaluable data it will furnish on consumer needs, tastes, and ability to spend. There are equally cogent reasons for the profession to support it since many important factors governing disbursements for sickness will be brought to light. According to the *J.A.M.A.*, an effort will be made to learn "the relation of family expenditures for medical care to expenditures for other specific goods and services," how this relationship varies with the size of the income, how occupation, size of family, and amount of earnings influence the selection of the type of medical care and "how expenditures differ among urban and rural families *** This should make it possible to learn who calls on the services of physicians, dentists, ophthalmologists and other specialists, who visit clinics ***" No outlay for any phase of medical care will be overlooked.

From the point of view of professional policy, it is extremely important that the medical data for each group will be presented in relation to outlays for food, clothing, shelter, recreation, education, and other purposes. This prevents the distorted perspective that comes from isolated examination of the costs of medical care without consideration of income and expenditures for other causes.

So far, field workers have encountered unexpected cooperation from those interviewed. The frank and full data obtained

as a result adds immeasurably to the value of the survey. Physicians, who stand to acquire information of genuine importance to their profession, should not hold back if they are called upon to cooperate in this project.

Real Health Examinations

Another school year has started and thousands of youngsters all over the state have had their first taste of the periodic health examination. Unfortunately in certain localities conditions are not such as to leave a very strong or favorable impression. When a school physician is required to go over forty or fifty children an hour, the examination cannot be very thorough. Superficiality not only defeats the purpose of the law requiring annual health certificates from school children but imbues the latter with scorn for the whole proceeding.

It is obvious that the family doctor is better qualified to pass on the health requirements of a child he has known and repeatedly examined than a strange physician who sees the youngster among hundreds of others and has time for only the most cursory inspection. The private practitioner is familiar with the home environment and appreciates hereditary factors and personal idiosyncrasies. Naturally he knows what emphasis to place on slight anatomical abnormalities and physiological aberrations. No matter how competent, the school physician is at a disadvantage in this respect. He has a single, brief opportunity to observe and cannot be blamed if he fails to evaluate or interpret his findings correctly.

It should not be difficult to make the family physician the universal school examiner. Even if parents are unable to pay, there is no reason why the child should be shunted to a strange practitioner. The schools must pay their examining physicians for admittedly unsatisfactory results. For very little more they could have every pupil examined by his own doctor and a system of real health examinations in force.

There is nothing utopian in this principle. It has worked successfully in emergency home medical relief. It is again proving its practicability in Workmen's Compensation. Individual school districts that have tried it are well-satisfied with the results. County medical societies should take the initiative in a drive to make it a universal practice.

Marijuana

The rapid increase in use within recent years of the narcotic drug marijuana has created a state of alarm among police officials and psychiatrists because of the augmentation of the already large number of drug addicts. Properly designated as *cannabis indica*, its effects were known to the ancients who termed it hashish. Unlike cocaine, morphine, and heroin, the user of marijuana rarely becomes an addict in the true sense of the word. There are no withdrawal symptoms upon discontinuing its use and no immediate after-effects follow the narcotic state induced by it.¹

In this country it is used in the form of cigarettes commonly called "reefers." It produces euphoria, flighty speech, and a sensation of a keen intellect. Visual hallucinations accompany a marked erotic stimulation. A profound disturbance of time perception makes the subject feel that minutes are hours. Constant and oft-repeated use of marijuana brings about a psychotic state which closely resembles a mixture of the schizophrenic and cyclothymic states.

The chief danger in the use of the drug lies in the release of whatever aggressive or sexual impulses may have been dormant in the individual user. In New York City many prisoners admit of its use and yet many of these had committed no crime prior to smoking the "weed." So important has the eradication of marijuana addiction become that the New York City police have under-

taken the destruction of tons upon tons of the plant deliberately cultivated in back yards and vacant lots. But the far-reaching import of this problem warrants more than local consideration. The Federal Narcotic Law which at present does not include marijuana in its scope, should be amended to the end that the use of this drug can be entirely wiped out. Fortunately this can be achieved since "reefer" smoking does not make an habitué of the user.

CURRENT COMMENT

DR. ALBERT EINSTEIN, speaking at the convocation of the University of the State of New York, among other things stated that "Darwin's theory of the struggle for existence and the selectivity connected with it has been cited by many people as authorization for the encouragement of the spirit of competition. In this manner some people have also tried to prove, pseudo-scientifically, the necessity of the destructive economic struggle of competition between individuals."

"But this is wrong," he continued, "because man owes his strength in the struggle for existence to the fact that he is a socially living animal ***"

Speaking on "Some Thoughts Concerning Education" Dr. Einstein mentioned the potential dangers of individual ambition. He said "Desire for approval and recognition is a healthy motive, but the desire to be acknowledged as better, stronger or more intelligent than a fellow being or fellow-scholar easily leads to an excessively egoistic psychological adjustment which may become injurious for the individual and for the community ***"

Dr. Einstein stressed the importance of independent thinkers, and went on to say that "The school should always have as its aim that the young man leave it as a harmonious personality, not as a specialist. *** If a person masters the fundamentals of his subject and has learned to think and work independently, he will surely find his way, and in addition will better be able to adapt himself to progress and changes than the person whose training principally consists in the acquiring of detailed knowledge. *** The development of general ability for independent thinking and judgment should always be placed foremost, not the acquisition of special knowledge ***"

IN THE *Health News* of October 12, issued by the State Department of Health at Albany we find a summary of the health conditions in New York State for August 1936 ***During the month of August, New York State experienced the lowest death rate on record (9.3 per 1,000 population) The infant mortality (37 deaths under one year per 1,000 live births) was the lowest ever recorded in August, only once before was the infant mortality lower in any month (36 in September 1935) The maternal mortality (43 deaths per 10,000 total births) was lower only once in the last fourteen years ***"

"IT RESTS WITH the medical profession, after all, to stop this step toward state medicine Through their constant association with hospitals, public and private, they are in the best position to say where costs can be reduced without sacrificing the quality of service.

"The strength of the demand for state medicine lies chiefly in the fact that medical costs frequently are beyond the means of patients who are entirely willing to pay to the limit of their ability As long as this condition obtains, the public is going to listen sympathetically to any proposal which promises to correct the situation.

"Physicians are enthusiastically enrolled against state medicine, but the public needs more than a phrase to realize the danger in the proposal ***"—From an editorial in the *San Diego* (California) *Union*

"***THERE ARE DIVERGENT philosophies of social evolution and antagonistic theories as to the proper function of the State in fostering the new or preserving the old patterns of social life—and medicine as a profession, jealous of its achievements and alive to its destiny—must examine these theories and philosophies and consider their respective consequences in the light of the public interest as viewed by the profession and of the profession's own peculiar needs as well"—*Westchester Medical Bulletin*

"HAVE WE COME OF AGE A HISTORIAN WONDERS" is the title of a thought provoking article by James Truslow Adams in *The New York Times Magazine* of October 18, from which we quote several parts ***The question whether as a people we have come of age is not merely a fanciful one. It has a practical import. If we suddenly find that affairs of the utmost importance to us

have to be transacted for us by a particular person, we are at once interested to know whether he is young or mature in experience and character *** We are not frontiersmen living solitary on a clearing, wholly independent of others What the nation is and does is of supreme importance to us, spelling comfort or penury, life or death, as history, unrolling before us over the whole earth today, indicates all too clearly Affairs of the utmost importance suddenly have to be handled for us by some one else—the nation Hence the maturity or immaturity of the nation takes on new interest."

Professor Adams looks about him and notes many signs of our immaturity—in our waste of the soil and forests, in the "lack of dignity or seriousness which marks our large gatherings, from class reunions to national political conventions" He questions whether we have "the firm character of maturity or merely the adaptability of youth" and concludes that American character is still "unformed and in the making"

The interesting article ends with the statement "Our nation, which is the sum of its citizens, seems still to me to be unformed, and until, through the development of its citizens *** it shall have come of age, no man can say what the future America will be."

"ECONOMIC UNCERTAINTY, produced in part by the withdrawal of donations and bequests because of high taxes, is demoralizing surgical work in American hospitals, the American College of Surgeons was told *** as it began its annual Congress. The statement was made by Dr Frank E. Adair, executive officer of Memorial Hospital, New York, at the hospital standardization conference of the Congress ***

"Dr Adair, after pointing out that many small hospitals had gone into bankruptcy, said 'Recently I noted that a distinguished American had died leaving an estate of between \$8,000,000 and \$9,000,000 His will, written a few years ago, directed that donations be made to eighteen charitable institutions A codicil to the will recently executed during the present years of the depression, stated that "because of the high estate taxes imposed by the Federal and state governments," it had become necessary to revoke the donations amounting to approximately \$1,000,000

'This practice has come to be a common occurrence. More such codicils have actually been attached to wills during the last

There is nothing utopian in this principle. It has worked successfully in emergency home medical relief. It is again proving its practicability in Workmen's Compensation. Individual school districts that have tried it are well-satisfied with the results. County medical societies should take the initiative in a drive to make it a universal practice.

To the Editor

In the editorial columns of the New York State Medical Journal for September [Sept. 1, page 1260] an article appeared on anesthesia which has aroused quite a bit of criticism, not only against the New York State Medical Society, but against our Society, "The American Society of Anesthetists," in that professional physician anesthetists and their work are given no recognition or support by the Journal of the New York State Medical Society.

Inasmuch as we have nearly 150 members of our Society who are paying dues to the New York State Medical Society, it seems but fitting that they should have the support of our State Society and their work should not be hampered by such editorial comments. In the future it seems but fair that any article on anesthesia should be submitted to the American Society of Anesthetists so that unjust and harmful statements be not printed. The author of this article does not seem to know the details of a good anesthetic practice or of the advances in the science and art of anesthesia we are trying to make possible.

I am enclosing a copy of a decision by the Bureau of Professional Licensing of the Commonwealth of Pennsylvania also reprint of an article which I read before the Erie County Medical Society in March

1936, and copy (uncorrected) which I am to read at Philadelphia October 20th before the American College of Surgeons.

Hoping some retractions of statements in this article can be made and anesthetists will be properly supported as members of the New York State Medical Society, I remain

Very truly yours,

L F ANDERSON, M.D.,

Chairman Special Committee
Erie County Medical Society
and

Member Legislative Committee,
American Society of Anesthetists
Chairman Special Committee,
New York State Anesthetists

October 13 1936

Note Obviously we would not submit editorial manuscript to any one other than our own Board. Our duty remains to interpret and comment upon policies regarding medicine and medical practice which have been adopted by the House of Delegates of our Society, its officers and committees. In this sense only do we express opinions. We call our correspondent's attention to our editorial statement *At the last meeting of our State Society a resolution was adopted the general purport of which consisted of seeking legal means to curb the administration of anesthetics by nurses*. Incidentally we reviewed the rise to favor of the nurse anesthetist. By no stretch of imagination did we condone this rise to favor. Perhaps a repudiation of the editorial in question will permit Dr L F Anderson to show us what he would have us retract. We assure Dr Anderson that the writer knows good anesthetic practice, and is fully aware of all advances made in this practice, since he is a practicing surgeon.—Editor

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network.

Thursday, Nov 5, 1 30 P.M.—*Speaker* Dr Guilford S Dudley, Director of Second Surgery Div. *Subject* "Cancer is Curable."

Thursday, Nov 12, 1 30 P.M.—*Speaker* Dr Walter T Dannreuther, Professor of Gynecology and Director of Department New York Post Graduate Medical School and Columbia University. *Subject* "The Education of the Doctor."

Thursday, Nov 19, 1 30 P.M.—*Speaker* Dr Charles E. Farr, President of the Medical Society of the County of New York. *Subject* "Appendicitis."

NEW YORK DIABETES ASSOCIATION

The November clinical meeting of the New York Diabetes Association will be devoted to the timely subject of protamine insulin. It will be held on November 13, at

8 30 P.M., in Room 20, New York Academy of Medicine. Papers will be presented by H Raule Gevelin, M.D., H O Mosenthal, M.D. and Howard F Root, M.D.

five years than have been added in the previous fifty years. But what has this to do with the subject under discussion? It is exactly this. Anything having to do with the stability of hospital income has both a direct and indirect influence on the work of the surgeon. Any uncertainty as to the ability of the hospital to meet its budget and continue its function has an enormous bearing on the quality of his work in a hospital. If you question this statement, examine for yourself the professional demoralization that took place in any one of the bankrupt hospitals before it closed its doors ***

'The public-spirited citizens who under normal conditions would like to be generous with hospitals have been made so uncertain as to their future that they cannot and are not running the risk which great liberality entails today. Uncertainty is probably the greatest single reason for our hospitals being in the unhappy condition

in which they now find themselves. Most hospitals find that their endowments have suffered a body blow. Bonds and other investments in the so-called legal securities are found dashed on the rocks of default, the income in some instances having greatly diminished or ceased altogether.

'As the depression has continued so many years, many people with modest means, formerly independent, have at last found themselves at the end of their capacity to pay for hospital service. The sick unemployed have crowded into the hospitals at alarming rates. Worry, inanition and their resultant sickness and disease have heaped a tremendous over-load on our hospitals. The government has seen fit for some curious reason to disregard this added burden of our hospitals. The government will give a man a job, but will not pay for his care when he gets sick.'—The foregoing has been taken from *The New York Herald Tribune* of October 19

INTRIGUING "KINKS" OF CARD SENSE

A clever skit by the chairman of the membership committee on poker hands and county society membership appears in an esteemed

Brooklyn contemporary which, by a slip of the types, carried this title across the top of the page

BULLETIN of the Medical Society of the County of Kinks

This particular kink runs thus

Card Sense

FOR THE SPECIAL BENEFIT OF SOLITAIRE PLAYERS

Not all physicians are accomplished card players. Many doctors can't tell a king from a jack or a heart from a club.

Some excel in bridge or pinochle, others in poker.

Some play golf, others are fine anglers.

Some paint or draw, others are recognized sculptors.

Each should have a hobby because the everyday grind is enervating.

Coming back to poker, here's a swell hand—

♥A—Membership card in your County Society

♥K—Membership card in your State Society

♥Q—Membership card in the A. M. A.

♥J—Membership card in the Library Association.

♥10—Membership card in a Special Section or Society

In Texas, men have been shot for holding five aces. Our doctors in Kings County holding this hand are up front.

For further information 'phone STerling 3-6900, ask for Miss Wightman.

Harry Meyersburg, M.D.,
Chairman, Membership Committee

More than twice as many children under fifteen are killed by accidents as by three common communicable diseases—measles, scarlet fever and diphtheria—a study of childhood fatalities by the United States Public Health Service discloses.

For children under one year old, mechanical suffocation leads the list of fatal accidents. At one and two years burns cause most fatal accidents. Automobile accidents, and burns lead at three years.

At four years, and from then up to fifteen, automobile accidents rank first as cause of accidental deaths and also outnumber deaths from the three diseases.

In the study, reported by William H. Gafaeer, senior statistician of the health service, the country was divided into three geographic areas.

The Northeastern region had most childhood automobile deaths per hundred thousand children.

of individuals, they decry special skills, they substitute rhetoric for reason. So we have another obligation, just as basic as the medical obligation, and that is a social obligation. We must reach out and interest ourselves in these questions which are quite outside medicine, but which need a generous skepticism to counteract what often seems to be a pathological optimism. We have not repaid our debt to society when we merely heal the sick. In some respects, the well need healing, too. That is to say, if we are not to have all our values, all our superiorities broken down. "One man," Mr. Dooley said, "is not only as good as another, but a damned sight better." There are no experts left. There are only simplifiers. And what are we doing about it?

This is not a matter of partisan party lines. The same kind of thinking is to be found everywhere. The public is coming to believe that it is capable of exercising its opinion, its judgment, on difficult technical problems, with no knowledge, no experience. Further than this, it expresses that opinion in response to a catch-word. It does not even make the effort to think a problem through on a rational basis, using the information, however inadequate, which

it has in its possession. These are symptoms of grave danger. Sooner than we think, we may see the complete triumph of mediocrity. And there is only one way in which we can make effectual remonstrance, and that is at the polls on election day. Yet I am told by those who have made inquiry that the proportion of doctors who vote is only one in three. Need I say that this is a disgraceful record? Need I urge you to consider its significance deeply, when so many public policies are formulating which may advance or retard the healing art? You know what various candidates stand for, and in general, if not specifically, what type of legislation may be expected of them. Your knowledge, your judgment, is ineffectual unless you vote.

After you have asked yourself why you are a doctor, ask yourself another question, a larger question. Are you a citizen, in fact rather than in name, if you fail to exercise the obligations of a citizen in exchange for its advantages? If we work in our own societies to preserve the integrity of medicine but fail in the larger society of American affairs to preserve the integrity of our civilization, efforts on the one part may easily be frustrated by inaction on the other.

A MEDICAL MAN'S PRAYER

President Samuel E. Harmon, of the South Carolina Medical Association, died before the state meeting when he was to deliver his presidential address, but "with characteristic foresight," says his state journal, he had completed the address, which is published in its pages. At its close we find this impressive passage:

The following is a Sunday Morning Prayer composed by Lieutenant Colonel Clayton E. Wheat, former chaplain of the Military Academy, West Point, that I have transformed to fit our profession.

"Oh God our Father, thou searcher of men's hearts, help us to draw near to Thee in sincerity and truth, may our religion be filled with gladness and may our worship of Thee be natural.

"Strengthen and increase our admiration for honest dealings and clean thinking, suffer not our hatred of hypocrisy and pretense ever to diminish, encourage us in our endeavor to live above the common level of life, make us to choose the harder right instead of the easier wrong, and let us never be content with a half truth when the whole can be won, endow us with courage that is born of loyalty to all that

is noble and worthy, that scorns to compromise with vice and injustice and knows no fear where truth and right are in jeopardy.

"Guard us against flippancy and irreverence in the sacred things of life. Grant us new ties of friendship and new opportunities of service, kindle our hearts in fellowship with those of cheerful countenance and soften our hearts with sympathy for those who sorrow and suffer. May we find genuine pleasure in clean and wholesome mirth and feel inherent disgust for all coarse minded humor. Help us in our work and in our recreation to keep ourselves physically strong, mentally awake, and morally straight, that we may thus better maintain the honor of our great profession untarnished and unsullied and acquit ourselves like men in our effort to realize the ideals of our noble profession in doing our duty to Thee and to our country, all of which we ask in the name of the great friend and master of men. Amen."

Let us live not for ourselves alone and the present, but for the greater and more intelligent life of the future, not for myself but for the truth that in life I have spoken. Not I, but the seed that in life I have sown shall pass into the ages. All about me shall have been forgotten save the truth that I have spoken, the things I have done.

Why Am I a Doctor?

FLOYD S. WINSLOW, M.D., Rochester
PRESIDENT, MEDICAL SOCIETY OF THE STATE OF NEW YORK

Why am I a doctor? Did you ever ask yourself this question? Perhaps it will not be amiss, once in a while, if we examine this basic question. It will be good for us to indulge in what might be called a "periodic self-examination."

Certainly we are not doctors because of the money that is in it. Generally speaking, our companions of early years who selected business pursuits have outstripped us in gathering together the collection of objects which represents monetary success. Why did we go into medicine? Why do we stay in medicine? Why do we live for, fight for, and sometimes die for medicine?

Glory? Where is the romance in our pursuit, for those who follow it? It is said that every ship is a romantic object but the one we are sailing in, and it may also be said that medicine has romance for those who do not practice it. We work in the quiet of the sick room, or the hospital, we walk daily with troubled humanity. Our satisfaction can only derive from the knowledge that we have performed our obligation to heal the sick, in this way paying the debt we owe for the accumulated knowledge and experience of the ages which has been made available to us.

Perhaps this feeling of responsibility is an ideal which we do not always reach, but is it any less our ideal? We can say, without fear of contradiction, that the great majority of doctors are imbued with the purpose to discharge this obligation. And I think the time has come when the public should know, should be definitely told, that the most important thing it should inquire about, when selecting a doctor, is whether he is genuinely interested in his calling, loves his profession, and is not only intent to attain ability as a physician, but feels a responsibility to advance the capacities of the medical profession as a whole. This is, as you know, the main object of medical societies. The man who has such a goal as this in mind as a destiny, is a man who can be fully trusted with the lives of men and women and children.

I will go even further than this and say that I think I stand here facing a group of men who have stood the test of this criterion, in other words, this test of character. You have joined your county medical society. You consider that when you were given the right to practice medicine, you assumed an obligation to do your part to see that medicine, as a profession, preserved its integrity. Now gentlemen, the only way integrity can be attained or retained, is to work for it. When you join your local medical society you work for the integrity of yourself and the group. You render yourself open to the criticism of your peers. You say, in effect, "I intend to behave myself, to put the interest of my patient above my own, to observe all the other provisions of the oath of Hippocrates, in letter and in spirit. And not only do I intend to do this, but by joining the county medical society *I have to do it*—I lay myself open to penalties if I do not."

I think the public should be told that a doctor who is a member of his county medical society is a better doctor on this account. I think a patient should ask his doctor, if he is not a member of the medical society, why he is not a member. It is possible, of course, that a physician may be of the highest rank, and not be a member, there is nothing compulsory about it, but as I go over in my mind the names of the physicians whom I find have lived so that their excellence is beyond possible question, I do not think I can name one who is not a member of his county medical society.

Now if our loyalty to our profession is merely another form of loyalty to society—to mankind—a point comes up which I wish now to mention. The world today is facing deep and important problems. Confusion abides in the minds of men. Quacks are abroad plying their trade in the realm of economics and sociology as well as in that of medicine. Large groups of people are assuming to know that which they do not know. They are contemptuous of the experience of the past, and of the experience

Address delivered at meeting of the Eighth District Branch, Medical Society of the State of New York, Buffalo, October 15, 1936

DISTRICT BRANCHES

First District Branch

That interest in case work, clinically presented in hospitals, is always alive and of prime importance in the minds of practicing physicians was proven again by the excellent attendance on October 7, at the thirtieth annual meeting of the First District Branch which comprises the counties of Bronx, Dutchess, Putnam, New York, Orange, Richmond, Rockland, and Westchester. The program consisted exclusively of clinics at the Morrisania City Hospital, 168 Street and Gerard Avenue, in the Bronx Borough of New York City. No less than fourteen different phases of clinical medicine and surgery, general and special, were featured as subjects for clinical study, by members of the staff of this large municipal hospital.

The Morrisania City Hospital houses 1200 patients, and its buildings are all of recent construction devised for efficient and effectual care of those committed to its care.

This program was presented

Obstetrical Surgery, Harry Aranow, M.D., F.A.C.S. and Staff. Prolapse of Uterus

Ophthalmology, Dr. Joseph Hory. Lid Plastic for Ectropion of Left Lower Lid.

General Surgery, George E. Milani, M.D. and Staff. Part I Operations: (1) For Carcinoma of Descending Colon. (2) For Carcinoma of Hepatic Flexure. Part II Demonstrations: (1) First Stage Lahey for Carcinoma of Rectum. (2) Operation for Closure of Intestinal Fistulae.

Urological Surgery, Terry M. Townsend, M.D., F.A.C.S. and Staff. 1 Suprapubic Prostatectomy (Benign Hypertrophy of Prostate). 2 Intraprostatic Injection for G.C. Prostatitis.

Pediatrics, Louis H. Barenberg, M.D. and Staff. 1 Tension Pneumothorax following Old Empyema, Dr. W. Levy. 2 Megacolon, Dr. D. Greene. 3 Pulmonary Infiltration for Diagnosis, Dr. H. Passachoff. 4 Tetany in New Born Twins, Dr. L. Barenberg. 5 Marasmus (Aldrich McClure Tests) Dr. N. Greenstein, and Dr. L. Barenberg. 6 Prophylaxis Against Contagious Diseases with Mother's Serum, Dr. L. Barenberg.

Oto-Laryngological Surgery, Clarence H. Smith, M.D., F.A.C.S. and Staff. 1 Retrograde Oesophageal Dilatation, L. T. Perrault, M.D. 2 Tonsillectomies, C. H. Smith and staff. 3 Simple Mastoids, C. H. Smith and staff.

Pathological presentations William Aronson, M.D. 1 Two cases of Multiple Myeloma.

Neuropsychiatry, S. Philip Goodhart, M.D. and Staff. 1 Cervical Cord Tumor. 2 Anterior Poliomyelitis with Psychogenic Loose of Sensation. 3 Carcinoma of Prostate with Metastasis to Spinal Cord. 4 Sub Arachnoid Hemorrhage.

Ophthalmology, Thomas H. Curtin, M.D. and Staff. 1 Bilateral Cataract. Morris Jaffe, M.D. 2 Detachment of Retina. Morris Jaffe, M.D. 3 Retina Cyst, Joseph Hory, M.D. 4 Carci-

noma of Lid, Joseph Hory, M.D. 5 Thrombosis of Central Retina Vein, Joseph Hory, M.D. 6 Hypertensive Obliterating and Arteritis of Retina, Joseph Hory, M.D. 7 Diabetic Chorioiditis with Retinitis Proliferans, Joseph Hory, M.D.

Neurosurgery, Sidney W. Gross, M.D. 1 Chordotomy for Intractable Pain.

Radiology, Samuel F. Weitzner, M.D. 1 Demonstration of Unusual X-Ray Films.

Surgical Diabetes, Part I Lecture on Diabetic Management of the Surgically Complicated. Frederick W. Williams, M.D. Part II Presentation of five cases of Diabetic Extremity Lesions with Discussion of Criteria and technic for amputation. Thomas J. O'Kane, M.D., F.A.C.S.

Radiation Therapy, W. Harris, M.D., Part I Role of a Tumor Clinic in a General Hospital. Part II Case Presentations: 1 Carcinoma of the Skin. 2 Carcinoma of the Oral Cavity. 3 Carcinoma of the Esophagus. 4 Carcinoma of the Breast. William Harris, M.D. and Samuel Richman, M.D.

Cardiac Edward Flood, M.D. Interesting Cardiac Cases.

Skeletal Surgery, William Klein, M.D., F.A.C.S. Treatment of Fracture of Femur.

Obstetrical Harry Aranow, M.D., F.A.C.S. and Staff. Part I Grand Rounds. Part II Presentation of Case—Toxemia of Pregnancy. Part III Management of the Occiput Posterior.

Particularly noticeable was the working of the Tumor Clinic.

Scientific exhibits were also shown as follows:

1 *Urological Pathology* Wax Models Courtesy of John Duff, M.D.

2 *Surgical Diabetes* Courtesy of Frederick W. Williams, M.D. and Thomas J. O'Kane, M.D., F.A.C.S.

3 *Pathological Exhibit* William Aronson, M.D.

4 *Cardiac Exhibit* Courtesy of N.Y. Cardiac Assoc.

5 *Electrocardiograph Exhibit* Edward R. Flood, M.D.

Executive Session

The following officers for 1937-8 were elected at the business meeting:

President, William C. Buntin, M.D., St. George, Staten Island. *First Vice-President*, Theodore West, M.D., Westchester. *Second Vice-President*, Alex. Selman, M.D., Rockland County. *Secretary*, Isidore J. Landsman, M.D., Bronx. *Treasurer*, Howard C. Taylor, Jr., M.D., Manhattan.

Dr. Nathan B. Van Etten, President of the Medical Board of Morrisania Hospital, welcomed the members, Dr. Peter Irving, Secretary of the State Society, spoke briefly on Society activities, and Dr. David J. Kaliski, Director of the Workmen's Compensation Committee explained details of operation of the new laws.

PROCEEDINGS OF THE EXECUTIVE COMMITTEE

In addition to minor routine business the Committee made several decisions at its regular meeting on October 8

In connection with a query from the Queens County Society as to the propriety of publication by a county society in the local press of a complete list of its members with their addresses it was considered that such a publication would be entirely in keeping with the Principles of Professional Conduct

Discussion of a suggestion from a member of the Society that the fee of two dollars for annual re-registration of the license to practice medicine be modified, it was thought impractical and unwise to seek amendment of the Medical Practice Act by which alone could change be made

The Committee on Public Health and Medical Education was authorized to contact the State Commissioner of Health for the purpose of developing a scheme for participation in the Maternal and Child Welfare provisions of the Social Security Act

Such a plan is in operation in New Jersey

A committee to confer with the State Hospital Association was appointed with the following personnel

Floyd S Winslow, Rochester, *Chairman*,
Frederic E. Elliott, Brooklyn
Thomas P Farmer, Syracuse
William A Groat, Syracuse
Augustus J Hambrook, Troy
Leo F Simpson, Rochester
Homer L Nelms, Albany
David J Kaliski, New York City

A recent resolution of the Board of Regents applying to foreign physicians was received with satisfaction

That on applications filed after October 15, 1936, no license of a legally constituted Board of Examiners in any foreign country shall be indorsed, pursuant to the provisions of Section 51 of the Education Law, until the applicant shall pass the licensing examination prescribed by law or Regents' rule.

It was understood that if an applicant has difficulty with English he must first pass the English Examination

NEW YORK HEART ASSOCIATION LECTURES

The New York Heart Association (Heart Committee of the New York Tuberculosis and Health Association, Inc) announces a series of lectures on heart diseases (Endorsed by New York Academy of Medicine) as follows Open to physicians without registration charge or admission fee

1 "Symptoms and Clinical Examination of the Cardiac Patient," Robert H Halsey, M D Tuesday, Nov 10, 1936, 4 30 P M New York Post Graduate Hospital, Erdmann Auditorium, Second Avenue—20th Street.

2 "X-ray and Fluoroscopy of the Heart," Clarence E. de La Chapelle, M D Tuesday, Nov 24, 1936, 4 30 P M Lenox Hill Hospital—Krackowizer Hall, Dispensary Building, Third Floor, Park Avenue—76th Street.

3 "Clinical Electrocardiography," Robert L. Levy, M D Tuesday, Dec 8, 1936, 4 30 P M College of Physicians and Surgeons Amphitheatre, Floor F, 630 West 168th Street.

4 "Hypertensive Heart Disease and Blood Pressure," Ernst P Boas, M D Tuesday, Dec. 22, 1936, 4 30 P M Mount Sinai Hospital, Blumenthal Auditorium, 99th Street between Madison and Fifth Avenues

5 "Cardiovascular Syphilis," Edwin P Maynard, Jr, M D Tuesday, Jan 12, 1937, 4 30 P M New York Academy of Medicine.

6 "The Heart in Thyroid Disease," Eugene DuBois, M D Tuesday, Jan 26, 1937, 4 30 P M Cornell Medical College, Room B-07, York Avenue between 69th and 70th Streets

7 "Arteriosclerotic Heart Disease," Harold E B Pardee, M D Tuesday, Feb 9, 1937, 4 30 P M New York Academy of Medicine, 2 East 103rd Street

8 "Arteriosclerotic Heart Disease," Harold E. B. Pardee, M D Tuesday, Feb 23, 1937, 4 30 P M New York Academy of Medicine, 2 East 103rd Street.

9 "Rheumatic Heart Disease," Arthur C DeGraff, M D Tuesday, March 9, 1937, 4 30 P M Bellevue Hospital, Surgical Amphitheatre, First Avenue—27th Street

10 "Rheumatic Heart Disease," Arthur C DeGraff, M D Tuesday, March 23, 1937, 4 30 P M Bellevue Hospital, Surgical Amphitheatre, First Avenue—27th Street.

11 "Treatment of Heart Disease, Including Irregularities of the Heart," Cary Eggleston, M D Tuesday, April 13, 1937, 4 30 P M Cornell Medical College, Room B-07, York Avenue between 69th and 70th Streets

12 "Treatment of Heart Disease, Including Irregularities of the Heart," Cary Eggleston, M D Tuesday, April 27, 1937, 4 30 P M Cornell Medical College, Room B-07, York Avenue between 69th and 70th streets

THE MICROBES

Two microbes sat on a pantry shelf
And watched, with expressions pained,
The milkmaid's stunts,

And both said at once
"Our relations are going to be strained"
—Indiana Division of Public Health

D Example of Typical Application Suppose we are dealing with a possible fracture of the shaft of the femur

- 1 The patient is covered with blankets
- 2 Morphine is administered, if available, under medical supervision
- 3 The foot, with or without the shoe on, is grasped firmly by an assistant with both hands placed laterally
- 4 Gentle, steady, firm traction is made in the axis of the extremity. Manual traction is maintained until splint traction is established.
- 5 While traction is being made the whole limb is slowly lifted several inches from the ground.
- 6 The half-ring splint is slipped from the outer side beneath the extremity
- 7 The side bars of the splint are placed in the median horizontal plane of the thigh so that the ring rests against the tuber ischi
- 8 The strap is buckled over the anterior surface of the thigh
- 9 The lower end of the splint rests against the body of the assistant who is still applying traction.
- 10 The ankle region is protected by cotton wadding, felt or shoe.
- 11 Traction hitch is applied, e.g., army traction strap, or muslin bandage about ankle, or adhesive plaster to leg
- 12 Traction hitch is fastened to the end of splint.
- 13 Traction is increased by Spanish windlass action, e.g., with tongue depressors and adhesive plaster, or long nail
- 14 The extremity is supported in the splint. This may be accomplished by muslin hammocks and clips applied before the splint is put on, or by bandage or triangular muslin slings after traction is applied
- 15 Lateral movement is prevented by a muslin bandage above and below the knee or by carrying a triangular sling used for support around the extremity and splint
- 16 The end of the splint is suspended to the stretcher bar or to the roof of the ambulance
- 17 A foot piece is advisable if transportation is to be prolonged.

Reference Transportation of the injured with particular reference to fractures of the extremities. Robert H. Kennedy, M.D. New York City

A complete list of exhibits follows. These were all prepared and set up by staff members of the Buffalo City Hospital as a tribute to the Eighth District Branch of the New York State Medical Society

- 1 Radiographic Demonstration of Complete Arterial System. Department of Anatomy and Radiology Buffalo City Hospital. C. R. Orr M.D., in cooperation with Eastman Kodak Company
- 2 Occupational Silicosis—Radiographic Demonstration of Various Stages of Pulmonary Changes in Occupational Dust. Department of Radiology C. R. Orr, M.D.
- 3 Bionogenic Carcinoma. Clinical Pathologic and Radiologic Aspects. Department of Pathology and Medicine. R. S. Rosedale, M.D., and D. R. McKay M.D.
- 4 Catheterization Method of Lymphoid Bronchography. Department of Radiology. G. D. Popoff, M.D.
- 5 Intracranial Pneumoencephalograms in Normal and Pathological Cases. Department of Neuro-Surgery W. B. Hamby M.D., and E. Friedman M.D.

6 Pathologic Lesions of the Tear Ducts Demonstrated by Lipiodol. Department of Ophthalmology W. F. King, M.D.

7 X-ray Films Illustrating Syphilitic Osteomyelitis. Department of Orthopedic Surgery Pio Blanco, M.D.

8 X-ray Demonstration of Foreign Bodies in the Lower Food and Air Passages. Department of Otolaryngology H. E. Bozer, M.D.

Fig 1 A. Murray-Jones Hinged Arm Splint. B. Reversible Half Ring Thomas Leg Splint. C. Supporting Bandage Tied Around Leg

9 Foreign Bodies Removed From the Lower Food and Air Passages. Department of Otolaryngology H. E. Bozer, M.D.

10 Normal Brain Anatomy. Dissections After the Method of Cunningham. Department of Neurology L. A. Marsh, M.D.

11 Clinical and Pathological Features of Brain Tumors. Department of Neuro-Surgery W. B. Hamby, M.D., I. A. Marsh, M.D. and E. Friedman, M.D.

12 Diagnosis of Lesions of the Mouth. Department of Diagnostic Medicine and Dentistry G. G. Martin, M.D., and S. W. Koepf, D.D.S.

13 A Clinical and Histopathological Demonstration of Common and Rarer Skin Diseases. Department of Dermatology R. Patterson, M.D. and H. Walker, M.D.

14 Gonorrhea. Department of Urology and Gynecology E. L. Brodie, M.D. H. A. LaForge, M.D. and A. J. Kelley, M.D.

15 Alveolar Abscess. Department of Dentistry S. W. Koepf, D.D.S.

16 Prevention and Treatment of Diphtheria. Department of Pediatrics F. J. Gustina, M.D.

16-A Recent Diphtheria Epidemic in Cheektowaga N. Y. Department of Hygiene and Public Health Medical School University of Buffalo W. S. Goodale, M.D. and F. J. Gustina, M.D.

17 Three Thousand Calorie Portions of Common Foods. Department of Dietetics. Ursula S. Senn, B.S.

18 Method of Constructing Dentures. Department of Dentistry P. Ginsberg, D.D.S., and S. W. Koepf, D.D.S.

19 Simplified Demonstration of the Principles of the Wassermann Reaction. Department of Dermatology R. Patterson, M.D.

19-A Historical Pictorial Development of the Buffalo City Hospital

20 Applied Practical Hematology. Department of Laboratories E. B. Hanan, M.D.

21 Acute Monocytic Leukemia. Department of Laboratories W. W. Jetter, M.D.

22 Circulation in the Living Kidney. Department of Anatomy, Medical School, University of Buffalo J. Graham Edwards, P.L.D.

Eighth District Branch

The thirtieth annual meeting of the Eighth District Branch was held in the Buffalo City Hospital on October 15, with the President, H Wolcott Ingham of Jamestown in the chair. An attendance of about 200 was registered.

At the morning session a medical clinic with six cases of congestive Heart Failure was conducted by Drs Allen A Jones and Abel Levitt of Buffalo. The patients exhibited different phases of origin and treatment. Dr Edward G Winkler of Buffalo showed an excellent detailed film demonstrating the technic of application of different types of forceps. Dr Francis C Goldsborough gave a brief discussion of Maternal Mortality in Erie County.

After luncheon there were short addresses by four of the State Society Officers. Dr Winslow, the President, spoke to the title of "Why I am a Doctor" (Full text will be found on page 1666 of this issue). Dr Irving, the Secretary, emphasized the readiness of the State organization to put into effect those activities of the Society which had been made the subjects of long study and this year reaching the point of action. Dr Goodrich, the President-Elect, complimented the Branch on the impulse to improve medical capacities obvious in the program and the remarkably large scientific exhibit. Dr Kaliski, Chairman of the Committee on Workmen's Compensation, mentioned problems that have arisen in the operation of the new laws, particularly with relation to arbitration of disputed bills and lifting of cases and in qualification of physicians for particular kinds of work.

In the afternoon Dr J H Donnelly, Dr D R McKay, and Dr Clifford Orr of Buffalo spoke with extensive x-ray slides on silicosis, covering clinic manifestations and radiographic diagnosis.

Dr Robert P Dobbie and associates described the working of the Fracture Clinic of the hospital. He spoke of three valuable adjuncts to a fracture clinic, a "fracture board", control radiographs, and a fracture cart. He demonstrated emergency traction for transportation with the slogan "Splint 'em where they lie" and also the procedure of making and applying moulded plaster splints, saying that "splints made to fit everybody seldom fit anybody". There followed ten cases of different fractures in each of which lay a practical lesson. The following general principles in the treatment of fractures were put forth

General Principles in the Treatment of Fractures

Emergency Treatment of Fractures Emphasizing Transportation in Traction

A Splint all fractures at the place of the accident in order to prevent the additional pain, displacement and soft-part injury that will otherwise result during the transportation of the patient from home to hospital or within the hospital.

B Indications for Use of Traction Splint

It is not necessary to make a positive diagnosis of fracture. The splint should be applied if there is any possibility of fracture between the hip joint and the foot and between the shoulder joint and the middle of the forearm. It should be used in both simple and compound fractures.

If there is a wound or if bone is projecting an antiseptic and sterile dressing, if available, should be applied before the splint is put on. If projecting bone disappears beneath the skin on the application of traction, no harm will result for such a patient requires an operative procedure as soon as possible to cleanse the entire surface of the wound. There is danger of increasing the area of contamination by the movement of fragments if traction is not applied. It is important that the one applying traction should observe if bone is projecting through the wound and report this fact to the doctor wherever the injured man is taken.

The splint should be applied wherever the patient is found, on the highway, in an elevator shaft, in the emergency room of a hospital, etc. Traction sufficient to prevent further damage should be applied before the injured man is moved.

C General Requirements of Application

There are certain standards that are necessary in the application of this general method. It does not make any difference what particular procedure is used so long as one appreciates what it is sought to accomplish.

In the use of traction there are six requirements. In the first place, there must be some adequate form of hitch, and it is necessary to protect the part beneath the hitch so that it will not be injured.

Secondly, the application of a traction hitch above the ankle or the wrist.

Thirdly, there must be some means of increasing traction by twisting so that the desired pull is obtained.

Fourthly, the extremity being in traction, it must be supported. One must not depend merely on traction for the entire support of the limb.

Fifthly, not only must it be supported from below, but lateral movement must be prevented.

Sixthly, the whole splint must be suspended in such manner that the heel will not, at any moment, rest on the ground, the floor of the ambulance, or elsewhere.

Historical Article

A HISTORY OF MEDICINE IN THE STATE OF NEW YORK AND THE COUNTY OF MONROE

FLORENCE A. COOKSLFY, B A, M A, *Rochester*
Librarian, Rochester Academy of Medicine

FOREWORD

Readers of this history are asked to bear in mind that it has not been written by one of the medical profession nor by the usual layman interested in the development of medicine but by a medical librarian and for that reason, a particular bias in favor of the medical man is evident. This possible error would be found, no doubt, in whatever a medical librarian might write of the profession, for those in daily contact with many physicians appreciate the high ethical deportment and the splendid character of these men of science to a greater degree than is possible with the less enlightened public.

The information contained in these pages has been gathered from the historical books in the various libraries of Rochester and other cities, from files of old newspapers, from transactions of State Medical Societies, and from the minute books of local

Medical Societies that are in the possession of the Rochester Academy of Medicine. The last named sources are the most interesting and here the reader sees the applicant for membership enter the Medical Society, reads abstracts of his prepared papers, his discussions or remarks during the meetings, sees him elected to office and last of all, reads resolutions regarding the loss the Society has suffered in his death. He seems so alive during the years through which his name appears upon the minutes, that he becomes another friend in the medical ranks and then with his passing, gives the reader-friend a sorrowing heart. Thus the interest and pleasure in reading these old records is ever tempered with sadness and adds still more to the deep admiration of the fineness of the profession felt by the medical librarians.

INTRODUCTION

The story of medicine is as fascinating as any part of history. The picture of suffering only slightly relieved or even increased by the ignorant healer of those very early days, using traditional rites, charms and nostrums, and crude surgery, gradually fades into one of struggle against ignorance and an attempt upon the part of pioneering medical men to relieve suffering and to extend life. We can feel but admiration and respect for the early practitioner traveling over bad roads to carry his healing art to the distressed. His medical knowledge was derived mostly from experience and many patients suffered from his unskilled but well meant efforts. He never rested. At night he was called out, hitching his weary horse by the light of a lantern, climbing wearily into the hard seat of his crusted buggy, and setting forth into the black night to ease a tortured mother or to save a dying child. His remuneration poorly repaid his hard work and his end-

less hours

Later we see him in the nineteenth century, struggling in his poverty to obtain a medical education, then cheerfully establishing himself in a district abounding with potential patients who soon demanded his help and comfort day and night. Few of these physicians became wealthy but they were generally loved and respected. Whereas in the early days the clergy attended the sick as well as the sinner, when the physician came forth, often religious consolation was demanded of the doctors. Into his willing ear is poured the sorrows of a suffering world and his kindly sympathy is understanding and healing.

We picture the doctor of today, not as a man worn by uncomfortable travel over unpaved roads but as one equally tired by the demands of the ill of today. His hours in an eight-hour-day world, are from twelve to twenty-four daily. He is "on call," at anyone's need, too often at anyone's whim.

43 *Conservation of Sight* Department of Ophthalmology W. F. King, M.D., and C. J. Streicher, M.D., in conjunction with the Buffalo Sight Conservation Society, Inc.

WANTED DATA ON HEREDITY

The Bureau of Human Heredity, 115, Gower Street, London, W.C.1, England, is gathering material dealing with human Genetics. The Bureau is directed by a Council representing medical and scientific bodies in Great Britain. It is affiliated to the International Human Heredity Committee, which ensures co-operation in all areas where research is proceeding.

The Council would be grateful to receive all available material from Institutions and individuals, furnishing well-authenticated data on the transmission of human traits whatever these may be. Pedigrees are particularly desired, twin studies and statistical researches are also relevant. As research workers and others who send in material may in some cases wish to retain the sole right of publication (or copyright) those

who so desire are asked to accompany their material with a statement to that effect.

Material should be given with all available details in regard to source, diagnostic symptoms and the name and address of the person or persons who vouch for accuracy. All such details will be regarded as strictly confidential. Reprints of published work would be most acceptable. Further, many authors when publishing material may also have collected a number of pedigrees which they have been unable to reproduce in detail. It is the object of the Council that such records, by being included in the Clearing House, should not be lost. Those wishing for a copy of the Standard International Pedigree Symbols may obtain one from the office. Announcements in regard to the services undertaken by the Bureau will be published from time to time.

DEATHS FROM ACUTE ACCIDENTAL POISONINGS

In the American home today are found many poison-containing compounds used as drugs, medicines, liniments, disinfectants, insecticides, cleaning fluids, and fuels. Many of these are labeled "poison", many apparently are not known to a large number of people to be capable of killing when ingested. Ignorance of their contents or sheer carelessness in not storing them safely

are responsible for the majority of the 1,400 deaths from poisons in the United States annually. About one-third of these deaths from acute accidental poisonings occur among children under five years of age, and of these, nearly one-half occur in the second year of life.—*Statistical Bulletin* of the Metropolitan Life Insurance Company.

We have been unable to confirm the report that the medical profession is trying to

interest Wallace in an apple-control bill—*Philadelphia Inquirer*

Chapter I

Early Practitioners and Development of Medical Schools

Early physicians, British Army physicians, European medical education Meager training of practitioners, First medical schools, Philadelphia College, 1763, Kings College and Doctors' Row, 1767 College of Physicians and Surgeons 1807, Union with Kings, 1814 Union with Columbia, 1860, Fairfield College 1812, Geneva College, 1834 Albany Medical School, 1839 University of City of New York 1837 and union with Bellevue 1898, University of Buffalo, 1846, Niagara University, 1893, Union with Buffalo 1898 Long Island Medical College, 1866, N. Y. Homeopathic Medical School 1860 Syracuse taking over Geneva College 1872, Post Graduate Medical School 1882 Limitations of early schools, poor equipment, dissection difficult

The drama of medicine resembles the lives of some of our great men, beginning in want, struggling for development of goodness and greatness in itself, giving unselfish service, and going unappreciated and lightly rewarded for its great work. We fail to appreciate that which we accept too easily, which is freely given and that which we do not understand. Our sanitary laws, our great medical institutions, and our skilled physicians have come to us through long years of struggle, not upon the part of the layman but through the efforts of the medical men themselves.

The greatest fear of our forefathers was not of want, for the man who tilled the soil, ate. Their dread was of disease, an ever-threatening presence. Today man fears hunger, his dependency upon his fellowman being so great, but he no longer fears disease. He rests in confidence knowing there are skilled men "on call" to care for him and battle for his preservation. He knows that public health laws protect him on every side. But he accepts this skilled attention and the protective laws much as he accepts all laws and justice without questioning whence they came or through whose efforts they were brought about. It is therefore fitting that we should pause in our rush of living to learn how living became assured.

Before considering the history of medicine in the County of Monroe, which is our chief concern in this record, it will be necessary to review first the development of medicine in the State of New York, to trace the beginning of legislative regulation of the practice of medicine and surgery and the building of medical schools.

The transactions of the Medical Society of the State of New York are a source of much information regarding the history of medicine in the state. The by-laws of the Society required its presidents to give an address at the annual meeting or forfeit the sum of twenty-five dollars and these

annual addresses were evidently prepared with great care, some pertained to diseases prevalent at the time but many were written regarding the development of medical practice and education in the state. There are much valuable data in these addresses and in the reports of Committees, regarding various colleges, medical and literary, as they were termed and considerable of this information may well be included in this review.

Dr McNaughton,¹ president of the Society in 1837, tells us that medical science was at low ebb in Europe when New York State was first settled. It had not emerged from the superstition and empiricism of the Middle Ages. The clergy acted as physicians, the barbers as surgeons, and ignorant females performed as midwives. Walsh, in his history of medicine in New York State, resents this statement which has been made so frequently. He names many famous physicians and surgeons living in Europe during that time. However, none of them came to early New York. The first clergymen arriving did endeavor to help the sick and with some success, many came prepared to practice some medicine in the new settlements. We read, for example, that the first medical society formed in this country was in East Jersey in 1766 and that its first president was Rev. Dr. Robert McKean.² The first regular physician to settle in New Amsterdam, Walsh says, was a Huguenot named Johannes LaMontague, who arrived in 1637. He was skilled in his profession and was honored with public offices, one of them being Vice-Director at Fort Orange, which later became Albany. "Zieckentroosters" or comforters of the sick, went from home to home like the visiting nurses of today and were well-regarded and recompensed. Dr. Abraham Staats, one of the pioneer physicians from Holland, settled in Albany and ministered to the sick of the surrounding country.

A civilized world with increasing luxuries and desires has brought in addition to old diseases of the body, new ailments of mind and body. The physician is a healer to whom we turn in our troubles.

Often we wonder why the medical man is of so fine a type. The explanation is sometimes given that medical schools are discriminating and select a high type of manhood. Again, that the long hard grind of acquiring a medical education gradually eliminates the unfit. Others claim that attendance upon the sick and the necessity of patiently caring for them inbreeds a finer feeling and requires a greater courtesy which colors the life of the physician. Certainly all of these have their influence. Nevertheless, it is not these factors alone which have produced the fineness of character which is exhibited today by the medical profession.

The profession calls the finest type of manhood to service. Those who enter the service for material gain or for social advantages are few. It is the desire to alleviate suffering manhood, the highest kind of philanthropy, that calls the medical student. The missionary going to foreign fields is upheld by his feeling of divine approval and ultimate reward. The physician's joy is in service. In reading old medical annals, we are impressed with the high ethical character of medical men and the ethical conduct which they demand of their coworkers. *Materia medica* has changed, surgical practice has made great strides, scientific discoveries have changed the habits of the world, even religion, Protestant, Jewish, and Catholic, has relaxed in the severity of its laws, yet the ethical code of the medical profession has endured. The doctor sits in patient silence amidst his slanderers, trusting that understanding and appreciation will follow later. He neither advertises his skill nor exploits his art, nor allows his coworker, if one should be so minded, to do so. Anyone daring to step from this high ethical plane, is thrust from the fold, a punishment so great in its results, that few dare risk incurring it.

The doctor has not been a business man in the past, he is not one today. Those who have become wealthy have done so usually through wise investments of small capital under the guidance of more materially minded persons. It is years before the

young practitioner can pay off the cost of his medical training and his office equipment. His fees are not consistent with the cost of his education. The public does not understand this and the medical man does not explain.

The physician is beloved by his patients, his kindly countenance is watched for, and his stay at the bedside is much too short to the mind of the suffering one. He is the greatest friend of the ill but forgotten when health returns. The installment on the radio or on the car, the interest on the mortgage, the needs of the day and some social requirements, all are paid for before the doctor is remembered. The arrival of his bill brings annoyance, pressure for payment not to be borne, he has to wait. Perhaps he is never paid. Nevertheless, he is expected to fly to the bedside immediately upon call whether in the day or at night. And he answers the call, as cheerfully and efficiently as he answered the earlier calls which brought no remuneration.

The poor we always have with us and all professions must contribute toward their care, but it is the medical profession that bears the heaviest burden. He gives his services not only to the individual but also proposes the establishment of hospitals, clinics, and asylums. Throughout their lives, medical men give abundantly of their medical skill without expectation of reward or even gratitude. Some of their greatest operations are performed upon the poor. There was a time when many of those unable to afford medical care, did without it rather than be "paupers" receiving free help. Today it is considered clever by many well able to pay, to get into a clinic and receive complete examinations, expensive treatments and drugs at cost. The physician recognizes this. He objects but not loudly. He is indignant yet continues to give his services, performing to the utmost of his skill, curing diseases, and comforting the distressed. He knows he is being put upon and that he is smiled at for being so gullible. Splendid in his foolishness, upon his high ethical plane he is a pattern for great living. We recognize it and we honor him always. He brings us into the world, he eases our going out and all the years between, he is our helper in time of need, our trusted and unfailing friend.

Early Practitioners and Development of Medical Schools

Early physicians, British Army physicians, European medical education, Meager training of practitioners, First medical schools Philadelphia College, 1763, Kings College and Doctors Riot, 1767, College of Physicians and Surgeons, 1807, Union with Kings, 1814 Union with Columbia, 1860, Fairfield College, 1812, Geneva College, 1834, Albany Medical School, 1839, University of City of New York 1837 and union with Bellevue, 1898, University of Buffalo, 1846, Niagara University, 1893, Union with Buffalo 1898, Long Island Medical College, 1860, N Y Homeopathic Medical School 1860 Syracuse taking over Geneva College, 1872 Post Graduate Medical School, 1882 Limitations of early schools, poor equipment dissection difficult

The drama of medicine resembles the lives of some of our great men, beginning in want, struggling for development of goodness and greatness in itself, giving unselfish service, and going unappreciated and lightly rewarded for its great work. We fail to appreciate that which we accept too easily, which is freely given and that which we do not understand. Our sanitary laws, our great medical institutions, and our skilled physicians have come to us through long years of struggle, not upon the part of the layman but through the efforts of the medical men themselves.

The greatest fear of our forefathers was not of want, for the man who tilled the soil, ate. Their dread was of disease, an ever-threatening presence. Today man fears hunger, his dependency upon his fellowman being so great, but he no longer fears disease. He rests in confidence knowing there are skilled men "on call" to care for him and battle for his preservation. He knows that public health laws protect him on every side. But he accepts this skilled attention and the protective laws much as he accepts all laws and justice without questioning whence they came or through whose efforts they were brought about. It is therefore fitting that we should pause in our rush of living to learn how living became assured.

Before considering the history of medicine in the County of Monroe, which is our chief concern in this record, it will be necessary to review first the development of medicine in the State of New York, to trace the beginning of legislative regulation of the practice of medicine and surgery and the building of medical schools.

The transactions of the Medical Society of the State of New York are a source of much information regarding the history of medicine in the state. The by-laws of the Society required its presidents to give an address at the annual meeting or forfeit the sum of twenty-five dollars and these

annual addresses were evidently prepared with great care, some pertained to diseases prevalent at the time but many were written regarding the development of medical practice and education in the state. There are much valuable data in these addresses and in the reports of Committees, regarding various colleges, medical and literary, as they were termed and considerable of this information may well be included in this review.

Dr McNaughton,¹ president of the Society in 1837, tells us that medical science was at low ebb in Europe when New York State was first settled. It had not emerged from the superstition and empiricism of the Middle Ages. The clergy acted as physicians, the barbers as surgeons, and ignorant females performed as midwives. Walsh, in his history of medicine in New York State, resents this statement which has been made so frequently. He names many famous physicians and surgeons living in Europe during that time. However, none of them came to early New York. The first clergymen arriving did endeavor to help the sick and with some success, many came prepared to practice some medicine in the new settlements. We read, for example, that the first medical society formed in this country was in East Jersey in 1766 and that its first president was Rev. Dr. Robert McKean.² The first regular physician to settle in New Amsterdam, Walsh says, was a Huguenot named Johannes Lamontague, who arrived in 1637. He was skilled in his profession and was honored with public offices, one of them being Vice-Director at Fort Orange, which later became Albany. "Zieckentroosters" or comforters of the sick, went from home to home like the visiting nurses of today and were well-regarded and recompensed. Dr. Abraham Staats, one of the pioneer physicians from Holland, settled in Albany and ministered to the sick of the surrounding country.

Dr Romaine, the first president of the New York County Medical Society and a fellow of the Royal College of Edinburgh, in his presidential address in 1811 before the State Society, stated that the English Army sent to this continent for the conquest of Canada, materially improved the condition of medicine in this state.

The English Army employed for that purpose left Europe accompanied by a highly respectable medical staff, most of whom landed in the city of New York and continued some years in the neighboring territories, affording opportunities to many young Americans of attending the military hospitals and receiving professional instruction as gave them afterwards consideration with the public. The physicians and surgeons of the Anglo-American Army gained the confidence of the public by their superior deportment and professional information. The military establishments in this state after the Canadian war required medical and surgical attendants, so that the people had the benefit of their professional advice. In this manner a new order of medical man was introduced into this community.

The military hospitals being mostly in this state, brought a diffusion of medical information through the state. Dr John Jones, Professor of surgery in the first medical school in New York and writer of the first medical textbook published in this country, was an American surgeon who served in the Revolutionary War and the French-Indian War.

Ship surgeons, many with very little training, landed in New York and remained as surgeons. The first surgeon in the New York Colony, Walsh states, was Herman Meynderts Van den Boogaerdt from Amsterdam in 1631, a ship surgeon who later became surgeon at Fort Orange and rendered valuable service until killed through treachery of the Indians. Because the ship surgeons were often unskilled but practicing in the colony, the Council of New Amsterdam gave to Dr LaMontague the right to issue permits to practice in the colony. In 1643, another skilled army surgeon, Paulus Van der Beeck settled in Brooklyn.⁸ Samuel Magapolensis, M.D., of Leyden is the first known university graduate to have come to New York, arriving in 1662 and was not only a physician but also collegiate pastor of the Dutch church in New Amsterdam. He was followed ten years later by Johannes Kerfbyle of the same place, then

Johnson, Brett, Lockhart, Van Buren, and Nicholl before 1800.⁶

After New York State came into British hands, the early educated physicians of the state came from the University of Edinburgh or from private schools in England. Only a few students from this country could afford to go abroad to study medicine. A number of graduates of Harvard and other colleges did study abroad and obtained doctorates in medicine. The general custom in this country was to study in the office of some practitioner until the instructor or the student himself, felt that he was ready to practice. Few were able to attend medical lectures even after some medical schools were available.

The preliminary attendance for the degree of doctor of medicine was expensive, the time to be consumed in its attainment was deemed too valuable, and it was not sought for, except among the residents of our larger and more populous cities, so its absence was not considered as a mark of want of medical knowledge. The number of gentlemen who held the degree of medicine in this State, thirty years ago (1796) did not exceed twenty.⁷

Indeed, there were in all the colonies together, 3500 practitioners, only 400 of whom were graduates.⁸ We may wonder at this small number of medical men in our own state, the state which now occupies a leading position in the country but we must remember that this was not true of the state at the time of the Revolutionary War. Walsh states that New York State was then only fifth in population, that Virginia had double its number of people, Pennsylvania twenty-five per cent more, North Carolina exceeded it, Massachusetts was far ahead, Maryland equal, and Connecticut almost equal to New York State. New York City was smaller than either Boston or Philadelphia.

Dr McNaughton⁹ deplored the lack of preliminary education before entering upon the study of medicine. He said many medical students were destitute of classical attainments and even their English education was imperfect. Some could not translate their diplomas. He felt that without a knowledge of Latin, it was too difficult to memorize anatomical, botanical, and chemical names.

The candidates for the medical degree are only required to be able to write an English dissertation on some medical subject with grammatical accuracy and freedom from gross

violations of orthography in addition to requisite knowledge of the several branches of medicine.

This, in marked contrast to the requirements for other professions, the clergy required four years preliminary study before becoming a theological student, and before studying law, one was required to have studied seven years in the office of a practicing attorney or to have had four years of classical study

Until 1776 only fifty-one degrees in medicine had been issued by American colleges, by 1780 about 250 had received degrees, and but five times that number had attended one course of lectures in some college. An applicant for a license to practice medicine had only to study in a private office for four years, after which he received from the Board of Censors of the County or State Society "a license for medicine, surgery or midwifery without having heard a lecture on anatomy, witnessed a human dissection, seen an important surgical operation or attended a woman in childbirth"¹⁰ The medical schools then existing had no hospitals nearby, except in New York City, so that it was impossible for many receiving a degree in medicine to witness a dissection. The laws of New York forbade dissection of any corpse except that of a convict. These convicts came from the prison at Auburn and only those dying in winter could be used, not more than two or three a season. That the sale of bodies occurred even in those days is shown by an article in the *Rochester Gazette* of 1821, copied from a Montreal paper reporting that "an evidence of hard times is that the bodies of two deceased children had been sold by their mother for anatomical purposes at the price of four dollars each"

Studying medicine only with a practitioner, without a course in a medical school made it easy for impostors to come into the state and open offices for practice. Quackery abounded everywhere and many assumed the title of doctor who "never had read a volume of medicine."¹⁰ Some boasted of intuitive knowledge or practiced what they termed Indian medicine, pretending a knowledge of the medicinal qualities of native herbs. President Wychoff in the transactions of 1876, stated that many root and herb doctors flourished less than a century before, especially in outlying districts where there was a scarcity of practitioners,

imitating Indian Medicine-men by using herbs, fasting, and sweating. Later these herb doctors formed a Thompsonian Society and created so great a controversy in the State that they caused a repeal of the laws regulating the practice of medicine. Wychoff adds that the chief legacy of the aborigines to medicine was the disclosure to the white man of the High Rock Spring at Saratoga. It is said that the Indians carried their adopted brother, Sir William Johnson in August 1767, to the medical fountain where he was cured of a stubborn dysentery and an unhealed wound received in a battle. Thus the spring became famous.

Colleges for instruction in theology, literature, and the arts were founded in Virginia and in New England almost as soon as the country was settled, Harvard in 1638, William and Mary in 1691, Yale in 1700, and Princeton in 1746, yet it was more than one hundred thirty years after Harvard was opened, before any medical schools were established.

Dr John Bard and Dr Peter Middleton of New York in 1750 gave private lectures in human anatomy but it was in Philadelphia that the first attempt was made to establish a medical school. Dr William Shippen⁹ in 1763 gave a course in anatomy to ten pupils and was joined by Dr Morgan. The trustees of the Philadelphia College were petitioned to establish a medical faculty under its auspices and consented. The first medical degrees were conferred there in 1769. In 1767 in New York City a medical faculty was organized under the charter of Kings College and opened in 1768 with six professors, Dr Peter Middleton of theory of physic, Dr James Smith of chemistry and materia medica, Dr Samuel Clossey of anatomy, Dr John Jones of surgery, Dr John V B Tennent of midwifery, and Dr Samuel Bard, professor of the practice of physic. Four of these professors, Wychoff says, were Americans who had graduated in medicine abroad, two at Leyden, one at Rheims, and one at Edinburgh. The Degree of Bachelor of Medicine was conferred in 1769 by that faculty upon Samuel Kissam and Robert Tucker and in the following year, 1770, the degree of Doctor of Medicine was conferred upon Robert Tucker. In 1771 the Philadelphia College conferred its first medical degrees upon four students. Although these degrees were obtained in the short period of

two to three years, we are assured that the standards for entrance were high, the applicant being required to have a proficiency in Latin and the natural sciences and to have served a three year apprenticeship with a physician. During the time of apprenticeship, the student read medical books, assisted the physician in his work, and prepared drugs. Indeed, the early medical students seemed to have much better preparation than those that came later.

A hospital connected with Kings College, later known as Columbia College, was built in 1769 but almost entirely destroyed by fire before quite finished, and was rebuilt in 1771. During the Revolutionary War the lectures ceased but the medical faculty was reorganized in 1792 and the school reopened. An interesting event occurred in connection with this hospital in 1788, called the Doctors' Mob or Doctors' Riot, which had significant importance at the time. We have spoken earlier of the difficulty of obtaining cadavers for dissection by students. Robbing of graves of their contents was not infrequent and the public was properly incensed. On April 15, 1788, a human arm was displayed from a rear window of the hospital and, some reports say, was playfully wagged at passersby. Word was quickly passed among the citizens, a multitude of whom stormed into the hospital and destroyed all the anatomical specimens and the medical students escaped from their hands, only through the intercession of the mayor who sent them to goal. The next day the mob searched the homes of the suspected doctors, then stormed the jail in repeated attempts to get the imprisoned students, and were finally forced to give up after being fired upon by the guards and several of the mob killed. A similar riot took place at the University of Maryland the following year.

The prosperity of Kings College waned when a rival medical school, the College of Physicians and Surgeons, opened in New York City in 1807, with an endowment of twenty thousand dollars from the legislature. The members of the faculty and Board of Trustees were the members, 139 in number, of the Medical Society of New York. The school opened with fifty-three students in 1807 and with seventy-six in 1808. In 1811, "eight doctorates were conferred, the largest number ever graduated in New York up to that time."¹¹ Rivalry

was keen between the two schools but they were united in 1814 and the faculty of the first was abolished, a number of its professors being included in the new union. The school now gained much fame but discord arose between the Faculty and the Board of Trustees, the Board consisting of physicians and laymen. One charge was that tuition fees exceeded the authorized amount by sixty per cent, another was that an inordinate percentage of the students was given the medical degree at one time, almost fifty per cent of them. It is easy to understand how such a condition could arise. The faculty received no compensation except student fees and it was easy to make fees exorbitant and to graduate students rapidly, for a short term attracted many students. A committee of investigation was appointed in 1825. It was found that the college had received from the State the amount of \$66,457.27 in endowment and \$75,000 for a botanical garden. The trustees asked that the professors be paid a salary and the tuition be used for the development of the school. The professors refused the conditions and resigned. The college was declared insolvent. The endowment had been spent and also, the anatomical museum that had cost the State \$7,000 purchased from a late professor of anatomy, had been sold by his heirs as private property. The botanical garden which had cost the State so much had proved too great a burden to maintain and had been bestowed upon Columbia College. A new faculty was appointed with Dr. John Watts, president. After a long struggle, the debts were finally paid in 1830 and the school gradually gained in popularity until in 1834, it was found necessary to erect new buildings. The college continued to flourish and in 1860 it was joined with Columbia College, "the trustees of Columbia College formally adopting the College of Physicians and Surgeons as the Medical Department of Columbia College" but it was not until 1891 that the union became complete and the College of Physicians and Surgeons conveyed all its property to Columbia College for the purpose of medical education.

In this short resume of the history of medicine in the State of New York, it will be impossible to give more than brief mention of the various medical schools of the state. Their full history is given elsewhere. We are interested only in giving a general picture of the development of medical

education and practice, so that we may better understand the progress of the practice of medicine in our own county [Monroe.]

The Regents of the University in 1812 organized another medical, this time at Fairfield in Herkimer County. It grew out of a medical school which had been established there by the trustees in 1809. The Legislature voted an endowment of fifteen thousand dollars which was to be raised by lottery. The school struggled along for six years, after which time the State granted an additional endowment of one thousand dollars for five years. The term of instruction was shortened one year and the school began to flourish. In 1834, there were 217 students, fifty-five of whom received the degree of Doctor of Medicine that year. Then there came a report of the need of a medical school in the western part of the state, where it was said one million people dwelt without a medical school. So it was in 1834 that Geneva College was allowed to form a medical faculty with the power to grant degrees in medicine. Dr McNaughton, writing in the transactions of 1840, says

There is not support for two respectable schools in the country and it is more than probable that at no distant period, one or both of the existing ones will be discontinued.

Neither of them was regarded as prospering at that time. Fairfield gradually lost its pupils while the school at Geneva gained in popularity and the last courses were given in Fairfield during 1839-40, only 105 students attending and twenty-six graduating with degrees of doctor of medicine. The medical school ceased to exist and the building became the property of the Fairfield Academy.

From 1835-37, Geneva graduated eight medical students annually, increasing to forty graduates during 1841-51. Geneva became well-known because it was there that the first woman student, Miss Blackwell, was admitted to study medicine, graduating in 1849. Although her presence in the school was admitted to be beneficial and she was highly regarded by the student body, it is interesting to read that her sister was refused admittance only a few years later.

The Transactions of 1858 gives the following table showing the attendance at these three colleges

	Physicians and Surgeons	Fairfield	Geneva	All Medical Colleges of the U S
1824-25	196	120		1970
1829-30	113	160		1716
1830-31	167	182		1898
1831-32	186	205		1759
1832-33	189	190		1729
1833-34	159	217		2236
1834-35	132	197	42	2299
1835-36	124	163	68	2652
1836-37	106	164	60	2393
1837-38	115	142	67	2309
1838-39	96	114	76	2387

Other medical schools established later in New York State we will mention but briefly. Albany Medical College opened in 1839, succeeding Dr Alden March's Practical School of Anatomy and Surgery, and not until 1881 was the Albany College of Pharmacy formed as a part of it. The Medical Department of the New York State Library, so much used by the physicians of all New York State, was begun when Albany Medical College gave its medical library to the state.

Two years earlier, on February 11, 1837, the University of the City of New York was authorized to establish a medical school and to give degrees in medicine which degrees, in themselves, gave a license to practice. In 1898 this school was united with the Bellevue Hospital Medical College. Bellevue Hospital was built in 1858 as the Almshouse Hospital of New Amsterdam, the Almshouse having been erected in 1734 after the third smallpox epidemic. Soon afterward the College of Physicians and Surgeons was opened, the hospital was used for clinical work by the students and it became a center of clinical teaching in New York, courses of lectures being given regularly by its staff. In 1861 a medical faculty was selected and the college opened and prospered up until 1898 when part of the buildings were destroyed by fire so that the classes were compelled to use the New York University for their sessions. This helped to consummate the proposed union of the two colleges.

The department of Medicine of the University of Buffalo was established in 1846. In 1893 the Niagara University Medical School was opened at Suspension Bridge, open to both men and women students. Niagara claims the honor of being the first to "suggest the need of four years of graded medical training and of definite preliminary education." In 1898 the college merged with the University of Buffalo, which had been prospering through the years.

two to three years, we are assured that the standards for entrance were high, the applicant being required to have a proficiency in Latin and the natural sciences and to have served a three year apprenticeship with a physician. During the time of apprenticeship, the student read medical books, assisted the physician in his work, and prepared drugs. Indeed, the early medical students seemed to have much better preparation than those that came later.

A hospital connected with Kings College, later known as Columbia College, was built in 1769 but almost entirely destroyed by fire before quite finished, and was rebuilt in 1771. During the Revolutionary War the lectures ceased but the medical faculty was reorganized in 1792 and the school reopened. An interesting event occurred in connection with this hospital in 1788, called the Doctors' Mob or Doctors' Riot, which had significant importance at the time. We have spoken earlier of the difficulty of obtaining cadavers for dissection by students. Robbing of graves of their contents was not infrequent and the public was properly incensed. On April 15, 1788, a human arm was displayed from a rear window of the hospital and, some reports say, was playfully wagged at passersby. Word was quickly passed among the citizens, a multitude of whom stormed into the hospital and destroyed all the anatomical specimens and the medical students escaped from their hands, only through the intercession of the mayor who sent them to goal. The next day the mob searched the homes of the suspected doctors, then stormed the jail in repeated attempts to get the imprisoned students, and were finally forced to give up after being fired upon by the guards and several of the mob killed. A similar riot took place at the University of Maryland the following year.

The prosperity of Kings College waned when a rival medical school, the College of Physicians and Surgeons, opened in New York City in 1807, with an endowment of twenty thousand dollars from the legislature. The members of the faculty and Board of Trustees were the members, 139 in number, of the Medical Society of New York. The school opened with fifty-three students in 1807 and with seventy-six in 1808. In 1811, "eight doctorates were conferred, the largest number ever graduated in New York up to that time"¹¹. Rivalry

was keen between the two schools but they were united in 1814 and the faculty of the first was abolished, a number of its professors being included in the new union. The school now gained much fame but discord arose between the Faculty and the Board of Trustees, the Board consisting of physicians and laymen. One charge was that tuition fees exceeded the authorized amount by sixty per cent, another was that an inordinate percentage of the students was given the medical degree at one time, almost fifty per cent of them. It is easy to understand how such a condition could arise. The faculty received no compensation except student fees and it was easy to make fees exorbitant and to graduate students rapidly, for a short term attracted many students. A committee of investigation was appointed in 1825. It was found that the college had received from the State the amount of \$66,457.27 in endowment and \$75,000 for a botanical garden. The trustees asked that the professors be paid a salary and the tuition be used for the development of the school. The professors refused the conditions and resigned. The college was declared insolvent. The endowment had been spent and also, the anatomical museum that had cost the State \$7,000 purchased from a late professor of anatomy, had been sold by his heirs as private property. The botanical garden which had cost the State so much had proved too great a burden to maintain and had been bestowed upon Columbia College. A new faculty was appointed with Dr. John Watts, president. After a long struggle, the debts were finally paid in 1830 and the school gradually gained in popularity until in 1834, it was found necessary to erect new buildings. The college continued to flourish and in 1860 it was joined with Columbia College, "the trustees of Columbia College formally adopting the College of Physicians and Surgeons as the Medical Department of Columbia College" but it was not until 1891 that the union became complete and the College of Physicians and Surgeons conveyed all its property to Columbia College for the purpose of medical education.

In this short resume of the history of medicine in the State of New York, it will be impossible to give more than brief mention of the various medical schools of the state. Their full history is given elsewhere. We are interested only in giving a general picture of the development of medical

it is only in the past fifty years or even less, that medical schools have attained to a high standard in this State and Country

The individual practitioner, his medical preparation, and his general background having been discussed at length, we turn to a consideration of physicians collectively, their associations, and the enactment of medical legislation. Preventive medicine has become a large part of the practice of medicine, and the present healthful conditions in the communities of New York State are due to these medical organizations and the laws they have promulgated to safeguard the health of the people under their care.

Chapter II

Rise of Medical Societies and the Code

Medical legislation first in New York City in 1760 in New York State in 1797 Incorporation of Medical Societies 1806 Medical journals of the time Examination of candidates, Medical ethics early system, 1822 High idealism Honorary degrees in medicine American Pharmacopeia, New era in medicine in State

Legislation to regulate the practice of medicine developed as pseudo-medical practitioners multiplied, and Chief Justice William Smith is quoted as saying

Few physicians among us are eminent for their skill. Quacks abound like locusts in Egypt and too many have recommended themselves to a full and profitable practice and subsistence. This is the less to be wondered at as the profession is under no kind of regulation. Loud as the call is, to our shame be it remembered, we have no law to protect the lives of the King's subjects from the malpractice of pretenders. Any man at his pleasure sets up for physician, apothecary and churgeon. No candidates are either examined or licensed or even sworn to fair practice.

Although the Province of New York held an annual assembly since 1663, it was not until 1760 that an act was passed to "regulate the practice of physic and surgery in the City of New York" The preamble stated, "Whereas, many ignorant and unskilled persons in Physic and Surgery in order to gain subsistence, do take upon themselves to administer physic and practice surgery in the City of New York, to the endangering of the lives and limbs of their patients, and many poor and ignorant persons who have been persuaded to become their patients, have been great sufferers thereby, therefore " The law required a certificate to practice, after the practitioner was examined by one of His Majesty's Council, the Judge of the Supreme

Court, the Attorney General, and the Mayor or any three of them, assisted by others selected by them Practicing without such certificate carried a penalty of five pounds Thus, the examiners of those wishing to practice medicine did not belong to the profession In 1792 the act was revised and applied to New York City and the County of New York It required that the examiners call to their assistance any three respectable practitioners with whom the student had not studied. This act did not affect those already in practice and for that reason New York City continued to have a great number of irregular practitioners

The first State legislative act to regulate the practice of medicine in the whole state was passed in 1797 All practitioners had to show evidence that they had practiced for two years just preceding or had studied for those two years The penalty for practicing without a license was twenty-five dollars A student must furnish a certificate from a respectable physician or surgeon that he has studied for four years and was well-qualified, if he had graduated from a literary college, three years were sufficient Those having a bachelor in medicine or a doctorate in medicine from one of the medical schools then existing, Philadelphia, Columbia or Harvard, had only to file their diplomas

After the establishment of State and County Medical Societies, there were three bodies with the power to license, (1) the

A charitable dispensary was erected in Brooklyn in 1856 and in the following year became St. John's Hospital. From this grew the Long Island Medical School, opening in 1860. In 1863 the first medical school for women, the New York Medical College for Women, opened with eighteen students. It was the first college of its kind in the world.

Homeopathic medical students had to obtain their medical instruction in other states until 1860 when the New York Homeopathic Hospital was opened. In 1887, the Flower Hospital was added to its buildings and to its name, the first medical school in New York to have its own hospital.

Geneva College in 1872 became the Medical Department of Syracuse and the library and museum were moved to Syracuse. Cornell University established its medical department in 1898 in New York City in order that it might be nearer the larger hospitals, though it was possible for students to take the first two years of medical instruction in Ithaca. Fordham University School of Medicine was opened at St. John's College, Fordham, N. Y., in 1905 in connection with the newly erected Fordham Hospital and in 1912 a College of Pharmacy was added.

The first postgraduate school of medicine was started in 1875 by the New York University Medical College, lasting seven years. In 1882, two postgraduate medical schools were opened in New York City, the New York Polyclinic and the New York Post-Graduate School.

We have digressed a long way from the early schools which we were discussing. Having hurriedly followed the establishing of many medical schools in this state, let us return to a consideration of the limitations of the very early schools.

The extent of the equipment of these early medical colleges is described by Dr. Alden in his presidential address in 1857.¹²

Our medical colleges or schools were limited to five and the hospitals in this country but a little more numerous, the whole apparatus, chemicals and chemical tests of the chemists' laboratory could almost be packed in a bushel, the anatomical museum of a college consisted of two or three smoky skeletons, a handful of disjointed bones and a few sparsely injected preparations and a pathological cabinet was not known in our country.

The need of further study in the field of anatomy and pathology was keenly felt by the practitioners. In 1854, Dr. Sprague,

president of the State Society spoke of this great need and said that an attempt to operate for the many diseases to which the human body is liable, without acquaintance with the minute anatomy of the body cannot except by rare accident result in anything but death to the patient. Yet, because of the law which forbade dissection of any but felons, the medical student and practitioner lacked this competent knowledge. He said that the four colleges then existing, the two in New York City and those in Geneva and Buffalo, received from Auburn and Sing Sing prisons an average of less than five bodies a year for the past ten years. It had been said in arguing against dissection of the bodies of paupers that the medical men desired to use the bodies of the poor for the benefit of the rich. He asked which was more humane and benevolent, to allow the medical student to cut up the living bodies of the poor in the public hospitals or to examine their bodies after the vital spark had fled. "Tell me then, who can," he said, "who is the true and tried and faithful friend of the humble poor? He who says to them, 'be ye warmed and fed,' but lifts not a hand to do it or he who diligently seeks opportunity to minister to their necessities?" He asked then that a law be enacted that the bodies of the poor who had died of their own vices, unwept by any, a disgrace to all, be given for dissection. No sorrowing relatives or friends could then be hurt and good could be brought out of evil.

In 1836 Dr. John H. Steel, President of the State Society said that the medical schools were in a flourishing condition and "it is now indeed, a rare occurrence for a candidate to present himself for the honors of the faculty, without being well instructed in not only the popular and leading opinions of the best medical authors of the day but in all the collateral branches of knowledge which constitute a profound and refined education."

In our reading of old books and papers, we note again and again that the criticism of the practitioner of those days is of those who obtained their training outside of medical schools. We are told that the medical schools of the early days had high requirements for entrance. A good medical course and examination were necessary before diplomas were granted and that later laxity crept into the schools both in requirements for admission and for graduation, and that

nal of Medicine and Collateral Sciences, a monthly journal of one hundred fifty pages, the *American Medical Gazette and Journal of Health*, a monthly of fifty pages, the *American Medical Monthly* of seventy-five pages, the *New York Medical Times*, a monthly of thirty-five pages, *Nelson's American Lancet and Weekly Journal of Medicine*, the *Buffalo Medical Journal and Monthly Review of Medical and Surgical Science*, of sixty pages and finally, the *American Journal of Insanity*, edited at the State "Lunatic" Asylum at Utica, a monthly of one hundred pages

But to return to the discussion of medical societies. The censors of the County and State Societies were busy examining candidates to practice medicine. A license from the State Society cost ten dollars and from a County Society, five dollars. These fees were added to the respective treasuries. The newly licensed practitioners were required to take the following oath

I, _____ do solemnly declare that I will honestly, virtuously and chastely conduct myself in the practice of physic and surgery, with the privilege of exercising which profession I am now to be invested, and that I will with fidelity and honor, do everything in my power for the benefit of the sick committed to my care.

This oath required in New York State at this time we have been studying, makes us think of the ethical code that prevails to this day among the medical profession and perhaps will continue forever. Let us digress again, to consider it for a short time.

A system of medical ethics was formed by the State Society in 1822, which concerned first, the personal character of the physician

A physician cannot successfully pass through his career without the aid of much fortitude of mind and a religious sense of all his obligation of conscience, honor and humanity. His personal character should therefore be that of a perfect gentleman and above all, be exempt from vulgarity of manners, habitual swearing, drunkenness, gambling or any species of debauchery and contempt for religious practice and feelings.

A further requirement was that he commit no crime, he should not degrade the character of the profession by "keeping a tavern, lottery office, gambling, victualling or playhouse. Any low trade or servile mercenary occupation is incompatible with

the dignity and independence of medical avocations." The penalty inflicted for violation of the code was forfeiture of the privileges of the profession.

The second division of the code concerned quackery. A physician should not associate with quacks professionally, he should not use patent medicines, he should not advertise his profession in any way.

The third was regarding consultations and said, first, that the distinction between surgeon and physician had no foundation in propriety, that the attending physician in calling another in consultation, remains in charge and the consultant is required to retire silently in case of disagreement, to keep the deliberations secret, to make as few visits as possible. Moreover, the attending physician is not to neglect to call a consulting physician when life or limb of patient is in jeopardy.

The fourth division of the code condemns violation of the confidence of families, the "prescribing of remedies if remedial means interfere with matrimonial rights," the infringement upon the rights of another practitioner or making improper charges against him, the visiting of patients without permission from the attending physician and there should be absolute secrecy regarding a physician's practice, even though his services were given to the poor without a fee.

Further, the code demands, a call for medical help shall be answered at once unless another patient is being attended and if two or more physicians arrive upon the scene, the first to arrive only shall stay, except when one of them shall be the family physician, then he shall be the one to remain. A physician shall not undercharge for his services in order to draw patronage, such conduct being undignified, nor shall he over-charge, so that the middle class will hesitate to seek medical aid. Physicians are admonished to belong to medical associations, that they may exchange information regarding their profession with others.

The last division of the code is in regard to forensic medicine. A physician should always aid in judicial investigations as far as he is able that justice may be done and they shall confer with each other on a case and not disagree if possible, if the physician has been related to the case, he must keep secret the facts known to him. The physician is to leave to the clergy the

Board of Censors of the County Societies, (2) the State Society, and (3) the Regents of the University of New York, the last of which gave the right to some of the medical faculties. From 1806 to 1907, this led to great diversity in requirements for a license and "in the contention of these, the legal regulation of the practice of medicine suffered untold harm"¹

Incorporation of medical societies "for the purpose of regulating the practice of physic and surgery" was ordered by a law passed in New York State Legislature in 1806. This law directed that the physicians and surgeons in each of the counties of the state, who were licensed to practice, meet in July of that year and, if five or more in number, form a medical society. Representatives of these County Societies were to constitute a State Society which should meet in Albany annually. Censors were to be appointed by each County Society for the purpose of examining medical students desiring to practice, licenses should be obtainable in no other way. Anyone practicing without a license could not collect for services. Students should present testimonials showing three years of study "but always preceding on the principle of improving the profession in future and not pressing too hard on the peculiar situation of those now in practice"

Within three months of the inacting of this state law, twenty County Societies had been formed. For the first time, the law now required that medical students should be examined by practitioners. A revision in 1809 allowed those with the degree of doctor of medicine to practice without examination. A further revision in 1813 added "that nothing in this act contained shall be construed to extend to debar any person from using or applying for the benefit of any sick person any roots, bark or herbs, the growth and produce of the United States". Thus, anyone might practice medicine if he used herbs indigent to this country. Dr Alexander Coventry, president of the State Society in 1825, said

While the regular physician is made subject to several years of study, a set of impostors, whose impudence is only equalled by their ignorance, are allowed to rob and murder the good citizens under the pretence of using only herbs and roots, the product of the country, although it is well known that they deal in the most powerful drugs in the shops, however ignorant, as they must be, of their composition and qualities

These were the persons who were known as botanical or botanik doctors

Anyone practicing without a license was not penalized if he received no fee or reward. "It makes the penalty attach, not to the practice of physic without the evidence of proper qualification but to the receipt of a fee therefor, it makes no account of the disastrous consequences of unlicensed ignorance but seriously attacks the petty emoluments of its craft, it, in effect, punishes the larceny while it acquits the homicide"²

By the law of 1818, the years of study were increased to four except that one year was deducted if the candidate had attended "classical lectures" for that period, after the age of sixteen or had attended a course of lectures in a medical school. He must be twenty-one years old to obtain a license to practice.

The first meeting of the State Society was held on February 3, 1807, in Albany, the year after the enactment of the law requiring the formation of County Societies. At this meeting, which was attended by seventeen delegates representing ten counties, the members were directed to furnish geographical and topographical surveys of their respective counties, together with a description of diseases prevalent there. A number of counties did furnish surveys and it is to be regretted that all did not do so, for we are thus deprived of much information that would probably be of value in this historical study.

Dr Rodgers, state president in 1813, reported in his address, that inflammatory diseases were prevalent in the state, due to rapid change in heat and cold that year and to the change in moisture and dryness of the atmosphere. The summer of 1811 with "severe hot portions" was followed by a mild winter except that January was intensely cold. He said that phthisis pulmonalis was more frequent than formerly and he puts part of the blame on the modern dress of young females. Dr Rodgers stated also, that he was unable to report any improvements in medicine that year as the war with England had prevented the reception of recent medical publications. The only medical journals published in New York State at that time were the *Medical Repository*, first printed in 1797 and the *Medical and Philosophical Register*. Sixty years later, we find seven medical journals published in the State the *New York Jour-*

nal of Medicine and Collateral Sciences, a monthly journal of one hundred fifty pages, the *American Medical Gazette and Journal of Health*, a monthly of fifty pages, the *American Medical Monthly* of seventy-five pages, the *New York Medical Times*, a monthly of thirty-five pages, *Nelson's American Lancet and Weekly Journal of Medicine*, the *Buffalo Medical Journal and Monthly Review of Medical and Surgical Science*, of sixty pages and finally, the *American Journal of Insanity*, edited at the State "Lunatic" Asylum at Utica, a monthly of one hundred pages

But to return to the discussion of medical societies. The censors of the County and State Societies were busy examining candidates to practice medicine. A license from the State Society cost ten dollars and from a County Society, five dollars. These fees were added to the respective treasures. The newly licensed practitioners were required to take the following oath

I, _____ do solemnly declare that I will honestly, virtuously and chastely conduct myself in the practice of physic and surgery, with the privilege of exercising which profession I am now to be invested, and that I will with fidelity and honor, do everything in my power for the benefit of the sick committed to my care.

This oath required in New York State at this time we have been studying, makes us think of the ethical code that prevails to this day among the medical profession and perhaps will continue forever. Let us digress again, to consider it for a short time.

A system of medical ethics was formed by the State Society in 1822, which concerned first, the personal character of the physician

A physician cannot successfully pass through his career without the aid of much fortitude of mind and a religious sense of all his obligation of conscience, honor and humanity. His personal character should therefore be that of a perfect gentleman and above all, be exempt from vulgarity of manners, habitual swearing, drunkenness, gambling or any species of debauchery and contempt for religious practice and feelings.*

A further requirement was that he commit no crime, he should not degrade the character of the profession by "keeping a tavern, lottery office, gambling, victualling or playhouse. Any low trade or servile mercenary occupation is incompatible with

the dignity and independence of medical avocations." The penalty inflicted for violation of the code was forfeiture of the privileges of the profession

The second division of the code concerned quackery. A physician should not associate with quacks professionally, he should not use patent medicines, he should not advertise his profession in any way.

The third was regarding consultations and said, first, that the distinction between surgeon and physician had no foundation in propriety, that the attending physician in calling another in consultation, remains in charge and the consultant is required to retire silently in case of disagreement, to keep the deliberations secret, to make as few visits as possible. Moreover, the attending physician is not to neglect to call a consulting physician when life or limb of patient is in jeopardy.

The fourth division of the code condemns violation of the confidence of families, the "prescribing of remedies if remedial means interfere with matrimonial rights," the infringement upon the rights of another practitioner or making improper charges against him, the visiting of patients without permission from the attending physician and there should be absolute secrecy regarding a physician's practice, even though his services were given to the poor without a fee.

Further, the code demands, a call for medical help shall be answered at once unless another patient is being attended and if two or more physicians arrive upon the scene, the first to arrive only shall stay, except when one of them shall be the family physician, then he shall be the one to remain. A physician shall not undercharge for his services in order to draw patronage, such conduct being undignified, nor shall he over-charge, so that the middle class will hesitate to seek medical aid. Physicians are admonished to belong to medical associations, that they may exchange information regarding their profession with others.

The last division of the code is in regard to forensic medicine. A physician should always aid in judicial investigations as far as he is able that justice may be done and they shall confer with each other on a case and not disagree if possible, if the physician has been related to the case, he must keep secret the facts known to him. The physician is to leave to the clergy the

task of announcing approaching death to the patient nor shall he advise in the settlement of worldly affairs

The high ethical calling of the medical man is emphasized repeatedly by the profession itself. Dr Jenks S Sprague in his annual address before the State Society in 1854, said

It becomes our duty to analyze all material things and to separate the hurtful from the harmless, to certify to man what is conducive to health, to happiness and longevity and to admonish him of the danger he incurs by an unrestrained indulgence in his appetites and passions. It is our business to indicate the consequences of a departure from the laws of health, as well as to cure the ills and heal the wounds we can not hinder, to admonish the healthy and to bring back to health and happiness, the diseased, the unfortunate and the erring. Charged with these high trusts, "what manner of man" ought we to be to command the confidence and respect of an intelligent community?

He answers the question by saying that nothing short of a general, a thorough, a liberal education can qualify for an honorable discharge of such duties. He demands sound learning and unswerving integrity as a basis of character in this profession.

Medical men have not only been healers of the sick but admonishers of the healthy, as Dr Sprague says and "it is surely creditable to the philanthropy of a profession which earns its daily bread by curing diseases, that it devotes so largely its time and its best energies to prevent their formation." The annals of the State and County Societies record many instances where the medical profession urged and obtained sanitary regulations, protecting the public (often against public wishes) against epidemics which had been so fatal in earlier years and how they constantly instructed the public in the principles of hygiene.

Again, we read, "As medicine is not a creed, not a dogma, but embraces the whole circle of science in its bearing upon health and life, that a standard unequivocally distinguishing the scientific physician from the dealer in cabalistic preparations be established, be it resolved, etc." and that Society urges further restrictions in the code.* Dr A Clark, President of the State Society in 1853, said

Medicine demands of us that we be men of integrity and honor, men of character, that she may be respected in us, men of charity

that she may be loved, men of learning that she may exercise her rightful authority, men of research and labor that she may claim from each something to be added to the general stock of knowledge.

Dr Coventry in his presidential address in 1855 expressed the same idea when he said

Medicine is no exception to the general rule that the quality of the individual will be in proportion to his natural capacity, his opportunity for improvement, his experience and habits of observation. The mere assumption of a name, as allopath, homeopath, hydropath or crono-thermal can never qualify a man for the responsible duties of the medical profession who is disqualified by nature or who has not qualified himself by study and observation. True medicine knows no such distinctions and the true physician is content with the designation the name imparts, viz a student of nature.

President Alexander Stevens, in his address in 1849, remarks

The vocation of a physician is the spirit of true Christianity in action. It consists not alone in healing the sick, in soothing the afflicted and recalling the wandering intellect but also in cherishing a love of peace and moderation among all men and in promoting moral and intellectual improvement.

Again in 1850, he says

Let it suffice that our profession is concerned for man at his birth and even before his birth, it follows him through his infancy and childhood, through manhood and old age, aiming to protect him from disease, to increase his strength, assuage his pains and diminish his infirmities, and to administer comfort and relief under all exigencies and under all circumstances, till exhausted nature sinks into the grave.

Not to quote Osler when remarking upon the high idealism of the medical profession, would be a grave omission. The "Beloved Physician" said *

We are here not to get all we can out of life for ourselves but to try to make the lives of others happier. The practice of medicine is an art, not a trade, a calling not a business, a calling in which your heart will be exercised equally with your head. Often the best part of your work will have nothing to do with potions and powders, but with the exercise of an influence of the strong upon the weak, of the righteous upon the wicked, of the wise upon the foolish. To you, as the trusted family counsellor, the father will come with his anxieties, the mother with her hidden grief, the daughter with her trials and the son with his follies. Courage and cheerfulness

will not only carry you over the rough places of life but will enable you to bring comfort and help to the weak hearted and will console you in the sad hours when like Uncle Toby, you have to whistle that you may not weep

You enter a noble heritage, made so by no efforts of your own but by the generations of men who have unselfishly sought to do the best they could for suffering mankind. Think not to light a light to shine before men that they may see your good works, contrawise, you belong to the great army of quiet workers, physicians and priests, sisters and nurses, all over the world, the members of which strive not neither do they cry, nor are their voices heard in the streets but to them is given the ministry of consolation in sorrow, need and sickness

When we read of these words directed by this great teacher to the young men of the profession, we can easily understand the admiration of medical men for Osler and appreciate their ethical plane

With these high standards realized, it is easier to understand the progress that medicine has made in our country and state, in the prevention of disease and in the preventive laws which have been enacted through the earnest efforts of the medical men. Also, it is understandable how the tremendous charitable work done in the medical clinics has developed through the great-heartedness of those in the profession, a charity seen nowhere except in medicine. Dr Clark said in 1853 in his address mentioned before

More than 100,000 in New York City annually receive the gratuitous services of the profession, enjoying the benefits of a kindness as sincere and a skill as profound as the wealth of the rich can buy

Dr Stevens stated also in his address of 1849 that one-third of the practice among the physicians in New York City at that time were without remuneration. Hospitals, almshouses, dispensaries, medical and surgical clinics, the eye infirmary, orphan and lying-in asylum, the colored home, and the institutions for the blind are mentioned as being attended by some of the most eminent physicians. He adds

A money making profession! Why, the number of destitute widows and orphans of medical men became so great that a few years since, an association was formed and is now in progress and successful operation, with a fund raised by their own contributions in New York, to secure from destitution after their death, their wives and children. It would have broken our hearts to have encountered them in our daily visits to the almshouses or asylums

He said that the reason so many entered the profession despite the small pecuniary reward, was because the study was delightful and because the practice brought higher rewards, that of the joy in saving and prolonging life

Again we have been discussing the individual, the medical man in his personal, ethical relation to his patient. We will return to a consideration of his relation to his coworkers in the medical society

A privilege of the State Society was to confer honorary degrees of doctor of medicine. Nominations for this honor were made by the County representatives and not more than four, later six, could be elected each year. They must be practitioners above the age of forty-five. It seems that the young graduate of a medical school sometimes scorned the older practitioner because of his lack of formal education and in turn, the experienced physicians regarded lightly the knowledge of the young graduate. The conferring of an honorary degree upon "aged" practitioners was supposed to ameliorate this condition. When finally all practitioners had a degree, this was no longer necessary. As far as the public was concerned, anyone with the title "Dr" except clergymen and professors, were considered physicians and one as good as another. A doctorate in medicine was important to the profession only

The treasuries of the medical societies, like most of their members, were at no times affluent. In 1816 it was reported at the annual meeting of the State Society that it was impossible to ascertain how much should have been in the treasury because of the insolvency of the treasurer at his death, however, almost one hundred dollars were at hand in the charge of the president and secretary. The medical societies of some counties even petitioned the Legislature for an allowance to pay the expenses of delegates in attending the annual meeting, as the County Societies could not afford the cost. This was not granted as far as we know

That an American Pharmacopeia be formed for use in this country was recommended by the State Society in 1818. So many were being used, such as Cove's, Thatcher's, the Edinburgh and London Dispensatories, the Massachusetts Medical Society, the New York Hospital, the London, the Dublin, and the Parisian Pharmacopeias, all varying so greatly, it was felt that there

was a need for a native pharmacopeia. It was claimed that the traveler received a different preparation under the same name in each village and also that the names of medicines were so multifarious that a name common in one town might be unknown in another or might even be applied to a very different medicine. So it was due to this State that such a book was published. A general convention was called in Washington in 1820 to form an American Pharmacopeia and delegates attended from the incorporated medical societies, the incorporated medical schools, the medical schools attached to incorporated colleges in the United States, and free voluntary associations in states having no incorporated medical colleges or schools.

It may be of interest in illustration of the extent of medical knowledge at that time, to quote part of the annual address of Dr. Coventry, president of the State Society in 1825.

In illustration of the treatment I prefer, in cases of strangers from healthy districts, when exposed to endemic fever, I will state a case which occurred in my practice. On the 10th of September, 1815, I was called to visit L. I, a young man of a full habit and robust form, who had never been sick before, he had just returned from the Cayuga marshes, having been a boatman on the Seneca River. His face was

flushed like scarlet, eyes red, terrible headache and full bounding pulse. A vein was opened in the arm and nearly two and one-half pounds of blood flowed before he felt faint. He now took a full dose of calomel and jalap but the heat and reaction reappearing in about one hour, he was placed on a chair before the door and two buckets of water from a spring poured through a sieve on his head, the shock was great, he went to bed with a chill, orders were given to repeat the effusion should the heat return, next morning he was evidently better, had got some sleep but the skin still being hot and the pulse rather strong, twenty ounces more were drawn from the arm and in about an hour after, the cold effusion. Repeated and strict orders were given to repeat it if the skin became hot and dry, his cathartic had operated and he continued to take lessened doses. On the third day he was convalescent and the mercury stopped.

Perhaps this is what is meant by the expression often heard, "heroic treatment." Medical treatment has come a long way since that time.

A GREAT BRITISH SURGEON

Many things combined to make Lord Moynihan the most successful British surgeon of modern times, says the *London Times* in a notice of his death in Leeds on September 7, at the age of seventy. It adds that with the exception of Lord Lister, he was the only surgeon to be created a peer. Nature had endowed him with a handsome person, good health, facility of speech, a pleasant voice, and a resolute character, together with great tact and a persuasive manner. To these gifts he added originality of ideas, enthusiasm, and an ability to carry through any scheme upon which he had set his heart. Above all, he was the complete surgeon, in teaching, in advising, and in operating. His students loved him, for he mingled his teaching with a kindly humor and light touches, and on more than one occasion he brought dozens of them to London, paying all their expenses.

After beginning his career as a general surgeon, he gradually devoted himself to the surgery of the stomach, the gall-bladder,

and the intestines. When he was a student the abdomen, except in the case of women, was only explored as a last resource, and usually with a fatal result. It has now become a safe operation of daily occurrence. To assist in obtaining this result Moynihan travelled widely, learning from the surgeons of the United States, France, Germany, and Italy. His operative success was great, and throughout his professional life he adopted the Hippocratic maxim that the patient should come first, and that everything should be done to make the ordeal as light as possible before, during, and after an operation. His fame spread steadily from Leeds throughout the North country until it reached London, where in due course he was elected president of the Royal College of Surgeons of England, being the first provincial surgeon to attain that high honor.

Lord Moynihan, who founded the *British Journal of Surgery*, did much to further the cause of scientific research in surgery.

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested.

Broome County

IT IS ESTIMATED that 300 cases of food poisoning occurred in Endicott and Johnson City in Broome County on September 19. All these cases have been attributed to the consumption of cream puffs sold by a single large bakery. Investigation of the outbreak was conducted by the local health authorities in cooperation with representatives of the State Department of Health.

DR. C. H. BERLINGHOF was elected president of the Binghamton Academy of Medicine, at the annual meeting held at the Broome County Tuberculosis hospital Sept 29.

Other officers elected are Vice president, Dr. C. B. Henry, of Binghamton, secretary, Dr. Romeyn T. Allen, of Binghamton, treasurer, Dr. John H. Martin.

The Academy voted unanimously to place its five oldest members, all still practicing, in honorary membership as an award for their lifetime of service and citizenship. They are Drs. F. W. Putman, J. W. Sheffield, L. H. Quackenbush, John H. Martin and C. W. Greene, all of Binghamton.

Cattaraugus County

DR. AND MRS. JOSEPH P. GAREN, the former health commissioner of the City of Olean, were honored Sept. 26 at a farewell dinner given by a group of about thirty-five friends at the Olean House.

Dr. Garen, who has been a member of the New York State Department of Health personnel for the past three months, has been granted a fellowship to Johns-Hopkins University where he plans to study additional public health courses for about eighteen months.

Dr. J. E. K. Morris presided as toastmaster. Brief addresses were given by Mayor Fred W. Forness, Jr., Dr. E. K. Kline, county laboratory director, who gave an alphabetic analysis of Dr. Garen's name.

Cayuga County

THE REGULAR MONTHLY meeting of the Woman's Auxiliary of the Cayuga County Medical Society was held at the Auburn City Hospital, Sept. 24, 18 members being present.

Columbia County

THE ANNUAL MEETING of the Columbia County Medical Society was held on Oct.

7 at the Hudson City hospital and was well attended. The meeting opened with a business session at 10:30 a.m. at which the election of officers took place with the following results: *President*—Dr. Hugh G. Henry, Germantown. *Vice Pres*—Dr. Robert Bowerhan, Copake. *Sect.-Treas*—Dr. H. C. Galster, Hudson, re-elected.

Dr. Frederick Hargrave, of Kinderhook, the retiring president, gave the president's address and the meeting adjourned for luncheon.

Genesee County

DR. FLOYD S. WINSLOW of Rochester, president of the Medical Society of the State of New York, gave an address at the Hotel Richmond, at a joint meeting of the Genesee County Medical Association and the Genesee County Bar Association in Batavia, Oct. 6.

Dr. Winslow's address was largely taken up with his experiences in coroner's work and investigation by the police department and county officials. There were sixty present. Among the guests were Justice Alonzo G. Hinkley of Buffalo, who is presiding at the present term of Supreme Court, and Raymond C. Vaughan of Buffalo, Republican candidate for justice of the Supreme Court.

Herkimer County

THE MEDICAL SOCIETY of the County of Herkimer met on Oct. 13 at the Mayfair, Middleville road, for the regular monthly session. Papers were read by Dr. J. J. McEvilly, first vice president, and Dr. G. A. Burgin, third vice president.

Jefferson County

A LUNCHEON, SPONSORED by the Jefferson County Medical Society to introduce an educational program designed to further the knowledge of social diseases, was held in the Black River Valley club on Oct. 5 with about 125 persons in attendance.

Various public officials including health officers were present. The luncheon was open to the public. Dr. George S. Bock, chairman of the public health committee of the county society, presided and introduced the speakers.

Kings County

PUBLIC HEALTH IS A secondary consid-

eration in the Pure Food and Drug Administration, asserted Dr Charles Solomon, chairman of the subcommittee on drugs of the Kings County Medical Society, on Oct. 13 in a talk at the Brooklyn Bureau of Charities Auditorium, 293 Schermerhorn St.

"Because of its legal limitations," said Dr Solomon, "the Pure Food and Drug Administration is powerless to protect the public from fraudulent nostrums. The law covers labels only, not general advertising. Cosmetics and obesity cures do not come under Federal supervision, even in interstate commerce, except as they make therapeutic claims."

He attacked a ruling of the Supreme Court which, he said, makes it possible for a manufacturer of a harmful patent medicine to escape punishment when no fraudulent designs can be proved.

The talk was given under the auspices of the Red Hook-Gowanus Health Center of New York City Health Department, Dr Leopold M. Rohr, health officer of the district, introduced Dr Solomon.

Monroe County

DR FLOYD S. WINSLOW, President of the State Society, acted as "guest editor" of the Rochester *Journal* for a day on October 6, and wrote an editorial on "The Doctor and the Public." He confessed that the doctors have been backward in teaching the public how to combat disease, and added:

But 'times change, and with them customs.' The medical profession is becoming vocal. Whereas it was formerly considered undignified for the doctor to address himself to the 'lay' public, we now feel that this is a most valuable contribution for us to make to the public welfare.

So the public may look for us in the future to explain more than we have in the past about what we are doing and planning. We may not always be as talented at telling as we might wish, but our friends, the newspapermen, will help us, I am sure. This will make us better doctors, and I suspect it will make the public better patients, too.

Readers sometimes come to a newspaper office to "lick the editor," and it is perhaps with this in mind that the *Journal* closes a colorful description of Dr Winslow by remarking that "one of his favorite feats of strength is driving a spike through a two-by-four with his bare hand as a hammer."

DR THERON W. KILMER, police surgeon at Hempstead, L. I., was guest speaker at a meeting of the Monroe County Medical Association in the Academy of Medicine Building on Oct. 13.

Doctor Theron, who is a member of the International Association of Police and Fire Surgeons and the International Identification Association, discussed the medical aspects of the drunken driver problem. Preceding the meeting, he was guest at a dinner in the University Club given by the society.

PLANS TO ENLIST THE active cooperation of every physician and nurse in the city and county in an educational project to combat communicable diseases were discussed at conferences of the County Medical Society, state and local health departments and the Tuberculosis and Health Association in Rochester on Oct. 6.

Among the activities to be carried on under medical society sponsorship, are a series of five Sunday afternoon lecture demonstrations on cancer and public meetings on syphilis control and tuberculosis prevention.

Dr William A. Brumfield Jr. of the State Department of Health, was the principal speaker at a joint conference of Monroe County and Rochester health officers and public health nurses at the Academy of Medicine in the evening.

Nassau County

PARALYSIS WHICH COMES from alcoholic addiction is caused by a deficiency in Vitamin B and can be corrected by abnormal dosage of that vitamin, Dr C. N. Colbert, psychiatrist at the Bellevue hospital told the Medical society of Nassau county in the Bar Association home, Mineola, on Sept. 29.

Introduced by Dr Louis H. Bauer, vice president of the society, Dr Colbert said in part, "In order to overcome the nervous disorders of these alcohol addicts, it was found necessary to give the victims four times the normal amounts of vitamin B. The vitamin regime was found efficacious even when the patient received between a pint and a quart of liquor a day."

New York County

WORLD-WIDE TRIBUTES, including a letter from President Roosevelt, to Dr William H. Park, retired director of the city's Bureau of Laboratories, were read on Oct. 6 at the dedication of the eight-story, \$700,000 William Hallock Park Laboratory, named in his honor, at the foot of East Sixteenth Street.

Mayor La Guardia, one of eleven speakers at the dedication, said it was difficult to get legislative appropriations for research laboratories, because "microbes don't vote." He disclosed, however, that when

he applied for a PWA loan for the new laboratory the application went through more speedily than other project applications totaling \$147,000,000, for which he had sometimes been criticized.

THE 439TH REGULAR meeting of the Society of Medical Jurisprudence was held at the New York Academy of Medicine on October 12. A paper was read on "Some Medico-legal Problems," by Karl M Bowman, M D, director, Division of Psychiatry, Bellevue Hospital and Hospitals of Greater New York.

Niagara County

DR. RUSSELL L CECIL of New York City gave an address on Pneumonia at a meeting of the Niagara County Medical society, on Oct. 13 at the Cataract House in Niagara Falls

Oneida County

DR. F M MILLER, member of the economics committee of the State Medical Society explained to Oneida County and neighboring county medical groups in Utica on Oct. 7 the stand of the state society on group hospital and health insurance.

ONEIDA COUNTY MEDICAL Society heard two scientific papers at a luncheon meeting Oct. 13 in Broadacres Sanatorium

Dr C H Baldwin spoke on "Tuberculosis of the Bones and Joints" and Dr J J Witt on "Tuberculosis in Children."

Onondaga County

DR. M A. OBREMSKI, also an outstanding amateur photographer, gave an address on "Infra-red Photography in Medicine" at a meeting of the Onondaga Medical Society in the University club, Syracuse, on Oct. 6

Dr Harold J Barnes of Brooklyn, president of the American Association of Medical Milk commissions, spoke on "Certified Milk and the Medical Profession"

Ontario County

DR. CHAUNCEY W GROVE of Geneva is the new president of the Ontario County Medical Society, elected at the annual meeting at Wenna Kenna, east shore of Canandaigua lake, on Oct. 13. He succeeds Dr Walter S Thomas of Clifton Springs. The new vice president is Dr Frederick C McClellan of Canandaigua and Dr Daniel A Eiselme of Shortsville was elected secretary and treasurer for the 40th consecutive term.

Drs Malcolm R Blakeslee of Shortsville, Joseph S Morabite of Geneva and A. G

Odell of Clifton Springs were named as members of the Board of Censors and Dr H J Knickerbocker of Geneva was elected delegate to the state convention with Dr M D Dickinson of Geneva alternate.

The next quarterly meeting will be held in Canandaigua on Jan 14

DR. C HARVEY JEWETT entertained Canandaigua Medical Society on Oct 1 at his home on North Main Street. Dr Leon A. Stetson read a paper on "The Leopard Changes His Spots"

Oswego County

THE NEGOTIATIONS BETWEEN the physicians of Oswego and the Mayor over the care of welfare patients reached a point on Oct. 10 when the Oswego Academy of Medicine sent the following communication, signed by Drs J F Burden, J T Dwyer, and C K. Elder, to President Taylor of the Welfare Department

Since Jan. 1, 1936, the physicians of the Oswego Academy of Medicine, have negotiated with the D P W in an effort to secure an amicable agreement in regard to fees for services rendered welfare patients in the Oswego hospital.

The efforts directed toward the adjustment of this matter have been unsuccessful

It is the consensus of opinion of the physicians that in view of the fact that we have for years carried on this work, largely without recompense, that due to existing economic conditions, we no longer feel that it is possible, or expedient, to continue to serve the D.P.W. without remuneration.

At a meeting of the Oswego Academy of Medicine, it was agreed that on and after twelve o'clock noon, on October 10, 1936, that no physician or surgeon will perform any professional services at the Oswego hospital in caring for welfare cases, unless a written authorization from the D P W., for the same be given the attending physician. The charges for services to welfare cases are to be based on prevailing rates, as charged private individuals in the community

Queens County

DR. JOHN L RICE, Health Commissioner, laid the cornerstone on Sept. 28 of the Astoria-Long Island City Health Center at Thirty-first Avenue and Fourteenth Street, Astoria, Queens. Dr James M Dobbins, president of the Medical Society of Queens, John J Halleran, acting Borough President of Queens, and Dr Margaret Barnard participated in the ceremonies

Mr Halleran, speaking at a luncheon given in celebration of the event by the Queens Chamber of Commerce and the Department of Health, at the rooms of the Chamber of Commerce of Long Island City, said that records of the Health De-

partment indicated that Queens was the healthiest county in the country. Commissioner Rice said that he hoped to see the time when nobody in Queens ever would be sick. Preventive medicine would hasten that time, he said, and the establishment of the Health Center was a step forward.

Other speakers were Dr Dobbins, Dr Luther Woodward and George Spargo. Dr H P Mencken presided.

THE WOMEN'S AUXILIARY of the Medical Society of the County of Queens held a luncheon bridge at the Amber Lantern, Flushing, on Oct 14. The Auxiliary also plans a luncheon, fashion show and bridge for the women attending the meeting of the Second District Branch of the State Medical Society on Nov 19. The gala Armistice Eve Dance will be held this year on the Starlight Roof of the Waldorf-Astoria, Manhattan.

Suffolk County

THE NEGOTIATIONS IN PROGRESS in various counties around the state on medical welfare work gave interest to a meeting of the Comitia Minora of the Suffolk County Medical Society on Sept 16. Welfare Commissioner Irving Williams was present by invitation. Dr Stakes, of the Medical Economics Committee, cited the following regulations which were unsatisfactory to the Economics Committee:

1 Restriction of number of visits to Welfare patients in hospitals to three visits a week.

2 Fees for Maternity Cases in which it is impossible for the specified number of pre-natal visits to be made.

3 Fees for tonsil operations.

4 Policy of Deputy Welfare Officers shopping around to obtain rates lower than those considered fair by the County Medical Society.

Tioga County

DR LOUIS D HYDE, of Owego, was nominated for president of the Tioga County Medical Society for the ensuing year at the annual Ladies' Day luncheon of the organization which was held on Sept 29 at the Iron Kettle Inn, Waverly. Dr Hyde is the present president.

All of the present officers were renominated. They include, beside Dr Hyde the following:

Dr Corbet S Johnson, of Spencer, vice-president.

Dr Ivan N Peterson, of Owego, secretary and treasurer.

The annual election will be held at the December meeting of the Society. A ladies' auxiliary is being formed.

Warren County

DR. LEONARD A HULSEBOSCH of Glens

Falls was re-elected president of the Warren County Medical Society at a meeting in The Queensbury at Glens Falls on Oct 8. Dr Edwin B Jenks of Bolton Landing was named vice president to succeed Dr George Bibby of Pottersville and Dr Morris Maslon of Glens Falls was re-elected secretary treasurer.

Dr B J Singleton was elected chairman of the Board of Censors, while Dr Stanley Edmunds and Dr E D B Elliott were also elected to the Board.

Several new members were admitted to the society and a resolution was adopted requesting the Warren County Board of Supervisors to engage the services of three public health nurses for the county.

Dr Felix A Schrenk and Dr Suzanne Schrenk of Glens Falls, husband and wife, were among those admitted.

Washington County

MEMBERS OF THE Washington County Medical Society, at their annual meeting Oct 6 in the Hudson Falls Court House, elected Dr John H Ring of Granville president. He succeeds Dr Edward V Farrell of Whitehall.

The meeting marked the election of Dr D M Vickers of Cambridge as secretary to succeed Dr Silas J Banker of Fort Edward. Dr Banker, holder of that office for thirty consecutive years, asked to be replaced. The society voted to make a permanent record in the society's minutes concerning his faithful duties.

Westchester County

ORGANIZATION OF CITIZENS advisory committees for the three-cents-a-day plan for hospital care in various key communities in Westchester County has been started. Representatives of the medical profession in every community will be invited to serve on the committees.

The first of these committees was started at Peekskill on September 23. Dr Franklin Kessler and Dr Bernard Loewy are members of the Peekskill committee.

The purpose of the committees, according to Hamilton Clarke, Westchester representative of the Associated Hospital Service of New York, is to broaden community interest in the plan, suggest ways of improving service, and to provide liaison between the plan and the public.

More than 15,000 Westchester residents are enrolled in this non-profit hospital plan, and nearly 1,000 have been hospitalized in Westchester.

All of the fifteen voluntary hospitals in the county offer the service to subscribers.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Physicians—Compensation—Requirement of License

An unusual case involving the rights of a person not licensed to practice medicine with respect to the use of a secret formula for the treatment of disease was recently decided by the Courts of a neighboring jurisdiction.*

The plaintiff in the action, a certain K. claimed to have discovered a formula or compound in the form of a paste, which he asserted to be a remedy for a certain specific disease. The salve was one to be administered by burning or melting in order that fumes and gases so released would take effect through the skin and pores of the body. K. claimed that he was the sole possessor of the secret formula for the remedy in question.

It seems that a certain A. sought out K. in connection with the possible use of the compound for himself, his wife, and children, and that K. furnished to him a quantity of the substance with instructions for its use and application in the treatment of the disease.

The transaction became the source of litigation when K. sought to recover a contracted fee from A. An action was brought by him to recover the sum of \$1,035. In his complaint or petition he made a preliminary statement as to his claimed ownership of the secret formula, and as to the fact that he was its discoverer. He, however, omitted any allegation to the effect that he was licensed or in any way qualified to engage in the practice of medicine.

His complaint averred that the contract which he had entered into with A. was in substance as follows: That K. would furnish sufficient quantities of the compound to treat A. and his family, and would provide directions as to the use of the preparation, that the defendant was to pay \$1,400, half of which was to be paid upon delivery of the remedy and the other half when the recipients of the treatment were found to be negative as to the disease.

The plaintiff charged that partial payment of the first half of the amount was all that had been paid. He asserted that before the use of the drug the patients had undergone scientific tests which had established that they had been afflicted with

the disease, but that after treatment additional tests being negative showed they were no longer suffering from the ailment. The complaint sought to recover from A. the balance due as his claimed contracted fee.

The defendant made an application to the Court to dismiss plaintiff's petition on the grounds that the plaintiff had no legal right to bring the suit, and that the petition did not state facts sufficient to constitute a cause of action. The Court ruled in favor of the defendant upon his application, and judgment was entered in his favor.

The plaintiff took an appeal from the ruling of the lower Court with the final result that the Appellate Court affirmed the said decision.

The pertinent section of the statute which defined the statute of medicine in that jurisdiction was as follows:

A person shall be regarded as practicing medicine*** within the meaning of this chapter who*** diagnoses for a fee or compensation of any kind, or prescribes, advises, recommends, administers or dispenses for a fee or compensation of any kind, direct or indirect, a drug or medicine, appliance, application, operation or treatment of whatever nature for the cure or relief of a disease.

It should be noted that the said definition of the practice of medicine is in effect similar to the New York statute which provides as follows:

***A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition.

Similar to the provisions of the New York statute the law of the jurisdiction in question provides specific penalties for the practice of medicine by anyone not properly licensed.

The Appellate Court determined that from the very terms of the plaintiff's own petition he agreed to furnish to the defendant a medical compound with directions

*Katsafaros v. Agathakos, 3 N. E. 2nd, 810

for its use in connection with the treatment of a specific disease. Such conduct it determined amounted to the practice of medicine and since there was no allegation in the petition that the plaintiff had ever received any certificate authorizing him to practice medicine the Court ruled that the acts which formed the basis of his complaint amounted to a violation of the law.

The Court in the course of its opinion discussed at some length the constitutional questions involved and determined that there was no violation of the plaintiff's constitutional rights which stood in the way of his being denied a cause of action by the statutes regulating the practice of medicine. In that connection the Court said in part:

The right to labor and enjoy the rewards thereof is a natural right which may not be unreasonably interfered with by the Legislature. Where, however, the pursuit concerns, in a direct manner, the public health and welfare and is of such a character as to require a special course of study or training, or experience, to qualify one to pursue such occupation with safety to the public interest, it is within the competency of the general assembly to enact reasonable regulations to protect the public against evils which may result from incapacity and ignorance*** The police power manifestly extends to the protection of life, limbs, health, comfort and the quiet of all persons and the protection of all property within the State. By this police power of the State persons and property are subjected to all kinds of restraints and burdens in order to secure the general comfort, health and prosperity of the State.

The Court came to the final conclusion that since the plaintiff's petition indicated that the basis of the contract for professional services was the practice of medicine without a license and that the contract was void because the consideration was illegal. Therefore the judgment appealed from was affirmed.

The ruling seems to be completely in accord with the language contained in a recent opinion handed down by our Court of Appeals* in which the Court said:

If it should appear upon the trial of this case that this agreement called for treatment by the deceased of the plaintiff for a disease, and that he was not a licensed physician, then the consideration, or part of it, for D's promise being illegal, the contract was void.

Alleged Improper Physical Examination

A middle aged woman received certain injuries while on shipboard. During the

completion of the cruise, first aid was rendered to her by the ship physician assisted by the stewardess. The officials of the shipping company arranged by radio for a doctor engaged in general practice to meet the ship when it arrived in port and make a physical examination of the woman for the purpose of ascertaining the nature and extent of her injuries. He appeared at the appointed time and went to the woman's cabin and made a general physical examination of her which included a rectal examination. It appeared, without the use of x-rays, that there was a possible fracture of the ankle and there appeared to be no basis of complaint with respect to pelvic injuries. Subsequent thereto, the doctor who made the examination rendered the woman no treatment and she left the ship and went under the care of her personal physician.

Thereafter, she instituted the suit against the shipping company and against the doctor who had made the physical examination at its request. While her claim against the shipping company included charges that it was responsible for her originally having sustained her injuries, her claim against the doctor was confined to charges that his physical examination had been improperly performed by him so as to aggravate her injuries, and had been made in the presence of a lay person thereby causing her humiliation.

Upon the trial of the action, the libellant undertook to testify that at the time the respondent doctor made the physical examination he was accompanied by a person representing the Claim Department of the Steamship Company and that he represented such person to be a doctor and that when the rectal examination was performed she was exposed to the view of the said lay person.

The doctor, however, testified that the examination was made by him in the usual manner and that those who were present, besides himself and the woman, were the Ship's doctor and a stewardess. There was no medical testimony which in any way showed that the examination which the respondent performed harmed the libellant, or in any way aggravated her condition.

The Court (a Court of Admiralty without a jury) ruled that the libellant had failed to make out her cause of action against the respondent doctor, thereby exonerating him of the charges that he had improperly conducted a physical examination. As to her causes of action against the Steamship Company, the Court also ruled against the libellant's claims.

*Brearton v. DeWitt, 252 N. Y. 495

Across the Desk

De Senectute 1936 Version

THE STORY IS TOLD of a chipper old retired Maine sea-captain of ninety-five summers who needed a fresh supply of tobacco for his pipe and asked his son, a young man of seventy-five, to get it for him. The son had a job of wood-chopping to do up in the back lot, so he asked his son, aged fifty-five, to get it, as he was going to the village anyway. At nightfall the grandson returned. "Where's my baccy?" shouted the old captain. "I'm sorry, grampa, I forgot it," said his grandson. "That's the h— of sending a boy," roared the old salt. "Next time I'll go myself."

Some such family age situation as this is now developing all over the country as the horizons of life-expectancy are pushed back farther and farther by medical science. We "point with pride," as the political spellbinders and welkin-ringers say, to the fifteen years added to the span of life in the last few decades. But do we stop to think what these added years mean in our family life? They may sometimes produce serious results. To add fifteen years to human life is splendid. A grand achievement. But all the effects of this temporary repulse of the grim reaper may not be equally fine. Statisticians say it means that our population will shift more and more into the "higher age brackets," an expression that leaves nearly everybody cold, not caring especially what brackets the population are in, if any.

Maybe they will sit up and take a little notice, however, if we translate it into everyday language, and say it means that we shall have a vast army of the aged, who will be saddled for care and support upon their children in the fifty and sixty year "brackets," no longer very well able to bear the burden. That this is no idle fancy is revealed by the astounding strength of the Townsend crusade for old-age pensions and the powerful movement for "old-age security." Such seismic disturbances do not happen without strong underlying causes, and the underlying cause here is the rapidly growing body of aged folk now demanding care.

Staying With Grandpa

It means that all over the land married couples who gave their early years to bringing up their children must now give up their later years to caring for their parents. It means that no time will ever come when such people will be free to lead their own lives and come and go as they like. When it is no longer, "Somebody must stay with the baby," then it is "Somebody must stay with grandpa." True, grandpa and grandma can be nicely cared for in a nursing home, where they will have every comfort and attention, but the cost ranges from \$25 to \$75 a week each, and up, which is beyond the purse of the man whose own hair is already tinged with the early frosts of age. The sons and daughters love those old people and are loyal to them, and so they buckle down to harder effort, make the old suits, hats and shoes do for another year, give up the trips to Europe, Florida, and California, and remain in loving bondage. But the situation is there just the same, and the more the miracles of medicine stave off the inevitable last debt to nature, the worse it will become.

Many of the very aged, it is true, are remarkably "chipper." They like to sally out for automobile rides or watch the flickering films at the movies. They joke and laugh with the young folks. But many, many others are in unending bodily misery or lead a half-alive, vegetable existence, partly blind and deaf, little aware of what is going on, in a dotage that is merely a distress to everybody. Here we see the reason for the enthusiastic support of any and every plan for old-age "security" and pensions.

"Security" on a Dollar a Day

The Townsend plan to give all the old folks \$200 a month apiece seems ridiculous to many critics because it is so high. But what about the "sane" and "practical" plans that have been worked out by the great minds in our halls of legislation and actually made law? The men of wisdom and sagacity at Washington and at the various

state capitals have provided "security" for the aged—and what do they get? Well, it appears that if the old fellows have succeeded in reaching sixty-five without a relative in the world who is worth a penny, then they are to get \$25 a month, or a little less than \$6 a week for room and board, clothing and any luxuries and hoopla that may occur to their minds. How this sum was arrived at is a mystery, unless it represents a saving over keeping them in the poor-house. All that can be said about it is that the oncoming tidal wave of feeling evident everywhere for adequate provision for the aged is likely to make our legislators think again, and think better.

A Happier Angle of It

Another feature of the prolongation of life that is happily a bit more cheerful is the fact that there is a corresponding prolongation of strength and energy into the "brackets" where formerly men had come to the end of their usefulness. Disregarding the intellectual pursuits, where the human brain has always seemed strangely ageless, no one can very well fail to notice the many workers with snowy hair successfully operating, for instance, our great railway trains which equal, if not surpass, any others in the world. This scribe was not long ago on a local train upstate where every member of the crew looked over sixty. While we are pridefully pointing to longer life, why not point with even more gusto to longer efficiency, longer ability, and vigor? Perhaps we discover here a reason why so many of the younger men cannot seem to

find work. The old fellows may be sticking to their posts ten years longer than they used to, preserved in health by the new discoveries of medicine. An elderly man in good physical fettle with years of experience and background is at least as good as a brash youngster who still has all his mistakes ahead of him, and the employers may be keeping the veterans on.

No Soft-Headed Sentimentality About It

Enough has been said, anyway, to indicate that we are in the midst of a great social readjustment in our family and business life, caused by the achievements of medical science. No one for a moment would regret them, or wish to cancel them, but we must face and solve successfully the problems they bring. No one would adopt the rough-and-ready plans of the Napoleonic economists who ordered the millions of little pigs slaughtered and the vast acreage of crops plowed under. The "children" of fifty, sixty and even seventy love their parents and wish to keep them as long as they can, but at the same time we have here a big national problem that will grow even larger with the inevitable advance of medical progress. The demand now for "old-age security" will be a mere whisper compared with the one twenty or thirty years from now. And no starvation dole of a dollar a day will do, either. People who imagine that this demand is just a soft-hearted or soft-headed piece of socialistic sentimentality will find that it is founded on the granite basis of facts, and that "facts are stubborn things." And the doctors are the men who started it.

"Are We Growing Bigger?" We Are

THIS QUESTION is the title of two articles, one in the *British Medical Journal* of June 6, and the other in the *Journal of the A.M.A.* of September 26. It is of course common knowledge that we are gaining in height and weight from generation to generation, but not everyone knows how much. Well, it appears that the boys and girls entering college now seem to average two inches taller and seven pounds heavier than their parents and grandparents did who entered the same schools. Measurements abroad tell the same story. Recruits in various European armies show a gain of one and one-half to four inches in average height in seventy years.

The growth in the height of college students in America is not uniform, but is continuous—there has been "a marked annual increase," amounting to approximately one centimeter, or 4 inch, every twelve and one-half years. Male students have shown a mean annual increase of .21 pounds during the past fifty years. Men, we are informed, "are today getting taller and slenderer, even though in absolute weight they exceed their parents." For the college women studied the mean increase in stature of the daughters over their mothers was 293 c.m. (1 $\frac{1}{8}$ in). The mean weight of the daughters was four pounds over that of the mothers in the group.

studied." The causes are uncertain, but some of those mentioned are better medical attention, better food, and more exercise. The mating of the improved stock brings still more improvement.

Imagination is at liberty to run riot in dreams of what the race may be like in another thousand years if these trends go on. You and I would then seem mere whipper-snappers. The "mean weight" of the daughters of that distant time may be terrible to contemplate. Take it all in all, and by and large, and around and about, the M.D.'s seem to be Burbanking the poor

old human race so completely that ere long it won't be able to recognize itself. Happily the changes so far seem to be mostly for the good, but when that "regimenting" of the doctors gets hold that we hear so much about, and the Great American Dictator mounts his throne, then all the improvements may be made on the folks who cast the right party ballot, and all the handicaps grafted on the opposition voters. A thousand other possibilities race through the fevered fancy, but perhaps they are better left to the mind of the reader.

RED CROSS ROLL CALL—NOVEMBER 11-26

From Armistice Day to Thanksgiving is the period very appropriately chosen for the annual Red Cross "roll call," which hopes to enlist 5,000,000 members.

The American Red Cross has helped the victims of 138 disasters in the past year, providing food, shelter, clothing, and medical care and assisting those families without resources to rebuild, repair, and refurnish their homes. No one knows where the next disaster will strike, but everyone can have a part in helping those who will be injured or made homeless by enrolling as a member in their local Red Cross Chapter during the annual Roll Call.

More than 80,000 persons were taught life saving and artificial respiration by the Red Cross last year. Red Cross public health nurses made more than a million visits to persons ill in their homes last year and taught 50,000 women and girls how to give intelligent bedside care by class instruction in Home Hygiene and Care of the Sick. Public health nursing service, disaster relief, first aid and life saving, assistance to veterans, and all other Red Cross activities are maintained by the membership dues. Not for several years has this great volunteer organization been called upon to give as large a measure of aid as during the Spring Floods and Tornadoes of 1936, when 200 counties in twenty eastern States were affected almost simultaneously. Despite the magnitude of the task, the Red Cross was able, by virtue of its countrywide organization of 12,700 Chapters and Branches and a trained national disaster staff, to meet the emergency needs of victims promptly, providing food, temporary shelter, clothing or medical care for more than 145,000

families. After this first help was given, the Red Cross stayed on the job to assist those families without resources to rebuild, repair, and refurnish their stricken homes.

The American people responded generously to the nationwide Red Cross appeal for funds to help the disaster victims, giving more than \$7,000,000 in a few weeks time, but this money would have been of little help in meeting the emergency if there had not been a competent agency like the Red Cross, able and ready to administer relief.

Last year the Red Cross started out to give aid to the victims of another type of disaster—highway disasters—which take an average daily toll of more than 100 lives and cause injury to nearly three times that number. To reduce death and needless suffering from highway accidents the Red Cross initiated a system of Highway Emergency First Aid Stations, now numbering more than 1000, along major routes of traffic to give intelligent help to accident victims before the doctor comes.

These emergency first aid stations are located outside of towns and cities, where medical aid and hospital facilities are at a minimum. Existing highway facilities, such as garages, filling stations, wayside inns, and State Police sub-stations are used. At least two persons at each station receive the standard training in first aid, and the station is provided with the necessary equipment and marked by an appropriate roadside sign.

The first aider cannot and does not attempt to render the services of a physician, but in many instances this layman's immediate assistance gives the doctor instead of the undertaker a client.

state capitals have provided "security" for the aged—and what do they get? Well, it appears that if the old fellows have succeeded in reaching sixty-five without a relative in the world who is worth a penny, then they are to get \$25 a month, or a little less than \$6 a week for room and board, clothing and any luxuries and hoopla that may occur to their minds. How this sum was arrived at is a mystery, unless it represents a saving over keeping them in the poor-house. All that can be said about it is that the oncoming tidal wave of feeling evident everywhere for adequate provision for the aged is likely to make our legislators think again, and think better.

A Happier Angle of It

Another feature of the prolongation of life that is happily a bit more cheerful is the fact that there is a corresponding prolongation of strength and energy into the "brackets" where formerly men had come to the end of their usefulness. Disregarding the intellectual pursuits, where the human brain has always seemed strangely ageless, no one can very well fail to notice the many workers with snowy hair successfully operating, for instance, our great railway trains which equal, if not surpass, any others in the world. This scribe was not long ago on a local train upstate where every member of the crew looked over sixty. While we are pridefully pointing to longer life, why not point with even more gusto to longer efficiency, longer ability, and vigor? Perhaps we discover here a reason why so many of the younger men cannot seem to

find work. The old fellows may be sticking to their posts ten years longer than they used to, preserved in health by the new discoveries of medicine. An elderly man in good physical fettle with years of experience and background is at least as good as a brash youngster who still has all his mistakes ahead of him, and the employers may be keeping the veterans on.

No Soft-Headed Sentimentality About It

Enough has been said, anyway, to indicate that we are in the midst of a great social readjustment in our family and business life, caused by the achievements of medical science. No one for a moment would regret them, or wish to cancel them, but we must face and solve successfully the problems they bring. No one would adopt the rough-and-ready plans of the Napoleonic economists who ordered the millions of little pigs slaughtered and the vast acreage of crops plowed under. The "children" of fifty, sixty and even seventy love their parents and wish to keep them as long as they can, but at the same time we have here a big national problem that will grow even larger with the inevitable advance of medical progress. The demand now for "old-age security" will be a mere whisper compared with the one twenty or thirty years from now. And no starvation dole of a dollar a day will do, either. People who imagine that this demand is just a soft-hearted or soft-headed piece of socialistic sentimentality will find that it is founded on the granite basis of facts, and that "facts are stubborn things." And the doctors are the men who started it.

"Are We Growing Bigger?" We Are

THIS QUESTION is the title of two articles, one in the *British Medical Journal* of June 6, and the other in the *Journal of the A.M.A.* of September 26. It is of course common knowledge that we are gaining in height and weight from generation to generation, but not everyone knows how much. Well, it appears that the boys and girls entering college now seem to average two inches taller and seven pounds heavier than their parents and grandparents did who entered the same schools. Measurements abroad tell the same story. Recruits in various European armies show a gain of one and one-half to four inches in average height in seventy years.

The growth in the height of college students in America is not uniform, but is continuous—there has been "a marked annual increase," amounting to approximately one centimeter, or 4 inch, every twelve and one-half years. Male students have shown a mean annual increase of .21 pounds during the past fifty years. Men, we are informed, "are today getting taller and slenderer, even though in absolute weight they exceed their parents." For the college women studied the mean increase in stature of the daughters over their mothers was 2.93 c.m. (1½ in.). The mean weight of the daughters was four pounds over that of the mothers in the group.

American Martyrs to Science Through the Roentgen Rays. By Percy Brown, M D Octavo of 276 pages, illustrated Springfield, Charles C Thomas, 1936 Cloth, \$3 50

In prefacing such a book as Dr Brown has produced, the title of the first chapter "The Cause and the Effect" is very appropriate.

A brief review of the causation of the pathological changes bringing about the results from over-exposure of human tissue by the roentgen rays and the description of these changes has been well expressed.

The greater part of the book is, as its title implies, biographic sketches of those early workers with the x-ray who died as the result of injuries obtained in the course of that work. It is to be noted that practically every one of this group of pioneers contributed much to the early development of roentgenology.

The whole book is not only a fitting tribute to these early workers with x-ray but is inspirational in showing the difficulties and handicaps under which the early workers in this branch labored and the large amount of important and scientific knowledge they gave to the world.

CHARLES EASTMOND
The Hair and Scalp A Clinical Study with a chapter on Hirsuties By Agnes Savill, M D Octavo of 288 pages, illustrated Baltimore, William Wood & Company 1935 Cloth, \$5 00

Although these subjects are treated in the usual texts on Dermatology, very few authoritative books have been written on the subject alone, or go into the matter in such detail as this one.

Dr Savill is particularly interested in the hair and scalp and their diseases, and has devoted many years to study and research in this particular field. Her book covers the subject thoroughly.

As Dr Savill states, the common diseases of the scalp and hair apparently so simple, prove to be some of the most puzzling problems of medicine and warrant more attention by the practitioner of medicine. While some of these maladies may be deemed trivial by the doctor they are of major importance to the sufferers and unless the doctor will give advice and treatment to these patients, they will seek advice elsewhere.

Dr Savill goes into detail on such subjects as brushing, washing and care of the hair and scalp. Hair fall, itching of the scalp, scaly condition of the scalp all of which should be treated by the doctor, are discussed and valuable information is given. A chapter on the Molecular structure and elastic properties of the hair by T W Astbury is both interesting and instructive.

This book is the most authoritative and detailed work on the hair and scalp published in some time. Not only dermatologists but every doctor will profit by reading it.

ALFRED POTTER
The Human Foot. Its Evolution, Physiology and Functional Disorders By Dudley J Morton. Octavo of 244 pages, illustrated. New York, Columbia University Press, 1935 Cloth, \$3 00

The author of this work needs no introduction to the orthopedist, for his research has spared no efforts in opening up new avenues in the study of the human foot.

This work covers very extensively and painstakingly the evolution, physiology and pathology of the foot. The mechanics of the foot in standing, walking and running, and their relations to body posture are covered most thoroughly.

A machine called, "The Staticometer" is illustrated and explained in the study of weight distribution and foot posture in stance.

The author stresses the importance of x-ray examination in all functional disorders of the feet and states that, "the most important physiological evidence to be obtained from the x-ray examination pertains to the distribution of weight upon the fifth metatarsal segment." He also stresses the importance of two views for study. Every important ailment of the foot is discussed in this work and the kind of foot wear to select is also advised.

JOSEPH I NEVINS
Medical Mycology Fungous Diseases of Men and Other Mammals By Carroll Williams Dodge, Ph D Quarto of 900 pages, illustrated. St. Louis, The C V Mosby Company 1935 Cloth, \$10 00

This book is primarily for botanists and others interested in having an excellent source of reference for the description and classification of fungi. The author, a recognized authority in this field, has written a text of nine hundred pages which includes an unusually complete bibliography of the existing literature through the first half of 1934, and a large number of illustrations. The chapters dealing with the general morphology and physiology of fungi, as well as those describing methods of isolation and microscopy, should prove valuable reading to all who are interested in pathogenic organisms. The discussion of the Trichophytaceae is a helpful account of the lesions produced by this widely distributed group of fungi, the etiological agents responsible for many of the infections caused in man.

The book is not for the general practitioner. It ought to be of considerable help

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers

REVIEWS

Medical Papers Dedicated to Henry Asbury Christian, Physician and Teacher Octavo of 1000 pages, illustrated Baltimore, Waverly Press, Inc 1936 Cloth, \$10 00

This Festschrift is published in honor of Professor Christian's 60th birthday—one of the outstanding clinicians of America, a man of great insight and energy, who has done so much for medical education and the training of good clinicians and clinical research workers

The list of contributors to this volume of one thousand pages are the present and past associates and house officers at the Peter Bent Brigham Hospital, and therefore a list of many of America's outstanding men of medicine. These hundred contributions are not only a great testimonial to a great man, but their numerous studies, reports, and original investigations into the causes,

diagnoses, and treatment of disease in all the departments of medicine are of great importance and merit

MEYER A. RABINOWITZ

Handbook of Surgery By Eric C Mekie, M B Duodecimo of 699 pages, illustrated Baltimore, William Wood & Company 1936 Cloth, \$4 50

This Hand-Book of Surgery accomplishes its avowed purpose as an aid to students reviewing for examinations

The contents cover the entire field of surgery in a brief but concise manner

The treatment outlined may at times be open to argument but, on the whole, is accurate and concise. As an aid to the student's notebook, or for quick reference the work is recommended

STANLEY B THOMAS

Skippy and David Explore The *New* BOOK OF KNOWLEDGE

"WE ARE a second generation Book of Knowledge family," writes Mrs E M Ritter, mother of the boys pictured above.

I was brought up on, and adored, the first edition that came out more than twenty five years ago. As soon as I saw your wonderful new edition, I felt that it was absolutely necessary for the boys to have it for their school work and for home reading. I notice how wonderfully you have kept up with all the changes. I don't want to praise my own children, but it certainly has put them along in school and it is the best possible background a child can be given."

Already in the Homes of
3,500,000 Children

The Book of Knowledge introduces the boy and girl to the world of knowledge in the happiest and most interesting way. By means of his own natural curiosity the child is led into the wide fields of Nature Study, Science, History, Biography, Literature, etc. 15,000 striking pictures provide visual edu-

cation in its simplest and finest form. The Book of Knowledge, already in the homes of 3,500,000 children, stores the mind with useful information and exerts profound influence on character.

The Trained Mind Wins

When your child starts asking "Why is the sky blue?" "Why are raindrops round?" and the hundred other daily questions that he speak an eager, inquiring mind, that is the moment, THE MOMENT OF INTEREST, when The Book of Knowledge should be at hand, to supply the right answers. The child whose questions are answered becomes a well-informed man or woman, with a clear, trained mind, prepared for success. In school days and in the fierce competition of grown-up years, the trained mind carries off the biggest prizes. The Beautiful Free Booklet will delight your boy or girl. Send for it today.

MORRIS L. RAKIETEN

Abortion Spontaneous and induced Medical and Social Aspects By Frederick J Taussig, M D Quarto of 536 pages, illustrated St Louis, The C V Mosby Company, 1936 Cloth, \$7 50

The author is especially qualified to write on this timely subject. His large practical experience in the diseases of women, and his work in public health matters, entitle him to speak with authority. He wrote the first special monograph on abortion in 1910, and even at that early date he strongly considered the possibilities and value of control of conception in limiting undesirable pregnancies.

This volume is the first to cover the ground with completeness and detail. It includes not only all the medical aspects of the subject, but also thoroughly discusses the social side of the question. In addition medico-legal matters are discussed at length, and one of the most interesting chapters is that which relates to abortion in animals.

The reader is at once impressed by the author's knowledge of the subject, and his ability to portray the facts in a clear, interesting and authoritative manner.

The medical profession and the public are deeply indebted to Dr Taussig for publishing such a complete volume on this very interesting problem.

WILLIAM S SMITH

A Textbook of Roentgenology The Roentgen Ray in Diagnosis and Treatment. By Bede J Michael Harrison, M B Octavo of 826 pages, illustrated Baltimore, William Wood & Company, 1936 Cloth, \$10 00

This work deals with roentgen diagnosis and therapy as applied to the various anatomical systems. The field of roentgenology has become so vast that one could not expect within a single volume a complete treatise of the many conditions included, but the author must be commended on having performed this difficult task unusually well. The section pertaining to the roentgen ray as a therapeutic agent has been given less attention than has that portion relating to diagnosis.

A very unique and desirable feature incorporated in this work is the discussion of the anatomical, physiological and pathological aspects of the many abnormal conditions treated. The text is well presented, in simple style, eliminating historical and other non-essential details.

Unfortunately, the illustrations are too few and those used lack detail and are poorly arranged, until this has been improved the book will appeal especially to those who have had some experience in roentgenology.

Well illustrated, this would undoubtedly become the most popular single volume on roentgenology.

RICHARD A. RENDICH

Recent Advances in Medicine Clinical Laboratory Therapeutic. By G E Beaumont & E C Dodds, M D Eighth edition Octavo of 450 pages, illustrated Philadelphia, P Blakiston's Son & Co, Inc. 1936 Cloth, \$5 00

The most important of the recent advances in internal medicine will be found in this deservedly popular book, lucidly described, and in sufficient detail to give the reader a working knowledge of the subject. The physician who desires to produce an artificial pneumothorax, and who has never before performed the procedure, will find here full and sufficient details. He who has been somewhat confused concerning the newer knowledge of vitamins and sex hormones, will in a few pages be given an excellent critical review of the entire subject. The reader will find a discussion of the high carbohydrate low fat diet in diabetes mellitus, the value of the urea clearance test as a criterion of renal function, details concerning the employment of the ketogenic diet in the treatment of urinary infections, and the importance of the histamine test in determining gastric acidity—to mention but a few of the multitude of subjects treated. In short space complete details of important laboratory procedures are given, and well chosen bibliographies are appended to each chapter. The book should be read by all who have not had the time or opportunity to follow up the advances in internal medicine as they have developed in recent years.

ISRAEL H. MARCUS

The Foot. By Norman C Lake, M D Octavo of 330 pages, illustrated Baltimore, William Wood & Company 1935 Cloth, \$4 50

This book is an attempt to familiarize the general practitioner with the minor ailments and treatment of foot conditions. A spread of knowledge of these lesions among the medical profession is certainly needed, but the author has described the subject perhaps too well, and for that reason, weakens his message. It is too exhaustively discussed to be of real practical value to the average practitioner.

The chapters on evolution, development, anatomy, and the evolution of footwear, although very excellent, might have been curtailed or left out for brevity and consequent clarity. This information is of value only to the deep student of the subject and is available in other thorough works on the subject. However, the book is recommended as of definite help to the general practitioner and possibly to the chiropodist.

JOSEPH B L'EPISCOP

Dyspepsia Complicating Arthritis

DYSPEPSIA in persons with the uric acid diathesis, or other forms of nitrogen excess in the system, is especially amenable to treatment with Vichy Celestins. Indeed, in all forms of dyspepsia, other than those arising from cancer or gastric or duodenal ulcer, physicians have found Vichy Celestins of distinct service.

A generous supply of Vichy Celestins and a booklet on its therapeutic value, with medical bibliography, will be sent on request

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines its step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

JENKINTOWN, PENNSYLVANIA

Athletics and Sportsmanship

School athletics can be the making of a boy—or his ruination. He can learn to be a good sport on the playing field—or a poor sport. And what he learns there is very likely to color his whole life. Parents sometimes give little thought to this vital side of school life. Yet it would be well worth their while to watch a few games of football, baseball and basketball, and see how the teams take a good licking.

When the other team is getting the upper hand, then the temptation comes to shrug responsibility for defeat, to blame someone else, to resort to shady tricks—in fact, to show a "yellow streak." That spirit infects an entire team sometimes, and parents will do well to keep their boys clear of such influences. Contracted in school days, they may in later life be fatal to all success.

Athletic instructors in our best private schools are on the watch every moment to eradicate any tendency of this sort. A school would not last long if it sent the boys home with a fine education in the head and a saffron tinge in the character.

FERNCLIFF SCHOOL for RETARDED CHILDREN

M M BRADY R.N., PRINCIPAL

A year round boarding school for children whose mental development has been retarded. Qualified, effective training in homelike cheerful surroundings. Spacious grounds—good food. Write for booklet.

"U S to Learn from Indian Farmers"

"The work done a thousand years ago by the Indian farmers of the Inca Empire for the control of erosion is far in advance of anything accomplished, even in our own times, by the most progressive countries," declared Charles Collier, Special Assistant to the Chief of the Soil Conservation Service of the United States Department of Agriculture, as he sailed October 9th in the Grace Liner Santa Lucia for Valparaiso in South America.

Mr Collier, son of John Collier, Commissioner of Indian Affairs, is being sent by the Department of Agriculture to conduct a study of the erosion control work of the Incas for the purpose of obtaining information that will be useful to agriculturists here in the United States. During his stay in South America he will motor 4,500 miles through the interior of Chile, Argentina, Bolivia and Peru.

"The Incas accomplished more than any country or race in the world along the lines of land conservation and their 'staircase' farms built along the steep mountainsides are the marvel of modern engineers" Mr Collier states "Lands that the Incas protected from erosion one thousand years ago have been cultivated with fine results ever since, while sections of land in the United States have become a total wreck in 50 years. Members of the Inca Empire showed amazing knowledge not only of soil erosion and its prevention but of irrigation and of the rotation of crops—ideas now being employed in the United States for the control of erosion. The Incas were the first conservationists of the Western World. They were also interested in the preservation of wild life and of forests and allowed hunting in only one-fourth of the Empire each year."

"The little we have learned of the agricultural pursuits of the Incas has come to us from archaeologists whose main interests lie elsewhere—no extensive investigation ever has been made of their attainments along the line of soil erosion prevention. We hope to be able to learn a great deal from the Incas which we may be able to use in this country, for their Empire was probably the most efficient in the development of agriculture—and their chief concern the conservation of natural resources."

Mr Collier, accompanied by his wife and brother, Donald Collier, prominent ethnologist, sailed on the Santa Lucia to Valparaiso. After spending a week in Chile they will resume

their 4,500-mile trip by crossing to Mendoza, Argentina, then north through Argentina to Tarija, Bolivia. They will continue across Bolivia to Lake Titicaca, visit the islands of Titicaca which Mr Collier stated are said to contain marvelous examples of the control of erosion. Their last lap will carry them to Peru, across the crest of the Andes to Cuzco, Cerro de Pasco, Arequipa and end at Lima which they expect to reach towards the end of December.

The Colliers will travel in a specially equipped Ford, with extra high wheels and rear bumper, a tank capable of holding gasoline for a 500-mile drive, and extra heavy springs. Their route will take them on little known roads carrying in altitudes from sea level to 15,000 feet. They are taking 5,000 feet of color film and dozens of rolls of film for still pictures which they expect to use in connection with their research work. Mr Collier's party will probably be the first to make such a drive as there is no record of any other party ever completing a trip by car on their proposed inland route.

Seaboard Orders De Luxe Coaches

With the large addition of a half-million dollar purchase of coaches to its recent huge order for track supplies, the Seaboard Air Line Railway is preparing for a season which, officials predict, will be the biggest in the road's history. The order for ten de luxe coaches, of the very latest design and completely air-conditioned, was placed by the receivers, L. R. Powell, Jr and Henry W. Anderson, with the Pullman Car & Manufacturing Company.

The ten coaches, which will cost \$500,000.00 will be placed in service on the Seaboard, between New York and Florida, beginning early in January. On Sept 5th, Seaboard purchased 10,000 tons of rails, and large quantities of other track supplies.

One of Atlantic City's Finest Hotels
 Pennsylvania Ave Paul Auchter, Mgr

yards wide, is opened to horsemen every year on October 1 and continues so until June 1 Bordered on one side by the Atlantic Ocean and on the other by the Boardwalk with its towering hotels, this bridle path provides an attractive setting for a brisk canter or a leisurely ride

A number of the small carts can also be seen daily as mothers take their children, too young for riding, for a drive. Both horses and carts may be obtained at any of the ten stands situated along the beach The stands open at about 7 A M, and close at 6 P M

For those who prefer riding along the woodland paths on the mainland, there are a number of academies ready to supply horses or equipment.

That degree of safety which applies to the Beach bridle path can also be associated with the Boardwalk bicycle lane. The 'walk, running along the beach for its entire length, is open to the cyclists from 6 A M to 9 A M Hundreds of guests at the beachfront hotels have made it a practice to take a bicycle ride each morning before breakfast and the shops where wheels may be rented frequently find it impossible to meet the demand.

With the opening of the football season, this resort's amusement places have become the rendezvous of the college students and alumni to celebrate the victory or forget the defeat with an enjoyable evening

Late Saturday afternoon finds hundreds of motorists driving to the shore after the eastern college games and staying over until the following evening Hotel grilles, night clubs, theatres and ocean piers have special weekend programs and are catering to unusually large crowds

After the closing of current conventions a huge crew will get busy tearing down the exhibits and when this is completed, start laying the turf for the indoor football games So large is the main hall of the great building that a full-sized gridiron can be laid out with room still remaining for a seating capacity of 15,000

The featured games in the hall this year will find Pennsylvania Military College as the host of both occasions The first is with the University of Delaware on November 7 and the second with LaSalle College on November 11 The military school will also stage a uniformed drill with men and horses on both nights

Meanwhile preparations are being completed for the start of the tenth annual open forum at the Community Center The first speaker on the program is Amelia Earhart, who speaks on November 8. She will be followed by Dr Stephen S Wise, president of the World

Jewish Congress, Elmer Rice, famous playwright, producer and author, Upton Close, radio commentator, Carlton Beals, journalist and world traveler, General Smedley D Butler, former fiery leader of the United States Marines, and Dr Emil Lengyel, popular lecturer on European affairs. There will also be a series of plays by the Philadelphia Guild Players.

The good weather finds a particularly large number of visiting equestrians out on the beach taking advantage of an opportunity to ride along the "safest bridle path in the world." The nearby golf courses at Seaview, Northfield, Linwood, Somers Point and Brigantine are also experiencing a holiday rush of enthusiasts while the Boardwalk bicycle lane, open from 6 a.m. to 9 a.m., is getting more than its share of cyclists daily.

Atlantic City is particularly attractive for participation in these sports at this time of the year and boating enthusiasts still frequent these waters while the visiting fishermen continue to boast of their catches. For those who prefer sport of a less vigorous nature there is usually a bridge tournament underway at one of the beachfront or large side-avenue hotels.

Railroads Serve 25,000,000 Meals Annually in Dining Cars

Approximately 25,000,000 meals a year!

That is the number prepared and served on trains to appease the appetites of the traveling public, according to tabulations just made by the Association of American Railroads.

This is a sizeable job particularly in view of the fact these meals must be served from dining car kitchens approximately 6½ feet wide and 16 feet long, while speeding over the rails, in many cases, at better than a mile a minute. There is little, if any, opportunity for any part of these meals to be prepared other than in that small space.

Before a dining car leaves a terminal, the steward must stock his car to meet the demands of the epicure and the passenger of simple tastes. Once the run begins, there is not always an opportunity for him to replenish his stock of supplies. The steward must see that an ample store of all things which will be needed is on his car before the train departs.

From experience, however, the steward knows that of every hundred patrons about 85 will want coffee and 15, tea. About 35 will ask for roast beef while the remainder will order chicken, fish, chops and steaks in about the order named. There is one thing upon which the steward can gamble with assurance, and that is the fact that apple pie is still the greatest

LOW RAIL FARES TO FLORIDA AND THE SOUTH VIA SEABOARD

One-way rail fares
in Pullman cars
from New York

Miami	\$41 45
St Petersburg	\$37 55
Tampa	\$36 80
Jacksonville	\$30 50
Savannah	\$25 35

Plus Pullman fare (reduced 1/3)
No surcharge

Also low fares to and from other points. Low round trip fares good for 15 days, 6 months and 9 months. Seaboard tickets to Florida permit you to visit *both* coasts of Florida. No extra rail cost, with liberal stopover privileges.

ALSO LOW COACH FARES

Take your auto with you by RAIL—only one extra passenger ticket at 4c a mile when two or more persons travel in Pullman cars.

4 famous Seaboard trains—all completely air-conditioned from New York and Eastern cities daily to Florida and the South.

For tickets and information consult your local ticket agent or S. B. Murdock, G.P.A., 8 W. 40th St., New York City, Tel. PEnn 6-3323 32.

The only completely air-conditioned trains to Florida and the South.

Meanwhile preparations are being completed for the start of the tenth annual open forum at the Community Center The first speaker on the program is Amelia Earhart, who speaks on November 8. She will be followed by Dr Stephen S Wise, president of the World

teen thousand barrels of apples, 1,625,000 oranges, and a half million grapefruit go to make up the larger part of the railroads' \$750,000 annual fruit bill

Ice cream ranks high in the public's choice of desserts, with the result that approximately 450,000 quarts are used on an average in each year, enough to provide a cone for every child in the United States between the ages of five and seven

Efficient movement of the 1,500 dining cars now in service is an intricate task. On some long runs a diner will continue through from one terminal to another with the crew sleeping on the train. In other cases, dining cars are cut off from trains at certain points at night and restored to other trains in the early hours of the following morning so that breakfast will be ready to serve to the early risers. However, through years of experience, an efficient and dependable system of handling dining cars has been developed. There can be no slip-up in the arrangements by the commissary departments of the railroads. They know, and the passenger knows, that even though the dining car has been detached in the night, another one will be available the next morning and breakfast will be served as usual.

In addition to the regular dining car service, a number of railroads have installed lunch counter cars. Some railroads extend their dining car service direct to the passenger in his coach seat.

Before being employed in the dining car service, stewards, chefs and waiters are required to undergo a course of instruction at schools maintained for this purpose by the railroads. One large Eastern railroad, for instance, has three such schools where there are reproductions, both in space and equipment, of the latest dining cars. These schools are conducted under the observation of skilled instruction forces, thus enabling "on the spot" correction of any cooking or service deficiencies before the novice is assigned to regular duty.

Mrs F D Roosevelt Gets Australia's National Flowers

"To Mrs. Roosevelt, wife of the President of the United States of America, with the compliments of Mrs. J. A. Lyons, wife of the Prime Minister of the Australian Commonwealth," reads a card on two cases sent by way of Canadian Pacific express for New York.

The cases contain dozens of "waratah," the

PRINCETON INN

Overlooking the Springdale Golf Club—Princeton, N. J.

The modern inn with a tang of real old-fashioned hospitality. Whether you come for zestful outdoor life—golf on the magnificent Springdale course adjoining, tennis, riding, or prefer quiet in this superb country, you will be well repaid for coming, if only to enjoy the perfect meals!

J. HOWARD SLOCUM—Manager

American dessert, exceeding all others in demand.

The average equipment of each dining car consists of 800 pieces of china, 980 table cloths and napkins, about 240 pieces of glassware, 550 pieces of silver, and 200 pantry and kitchenware items such as pots, pans, knives, brushes, pails, and other utensils used by the chef and his assistants. Approximately 1,000 dishes of all kinds must be washed during a meal period by one man at a sink less than two feet square.

Some idea as to the immensity of this job of furnishing food to the hungry travelers can be gained by the fact that the dining rooms of the hotel reputed to be the largest in the world, average approximately one and a half million meals a year. One large eastern railroad alone serves nearly two and one-half million meals a year on its diners.

Installation of air-conditioned dining cars and train equipment, according to officers in charge of the dining car service, has resulted in an increase in the number of orders for heavier meals.

That the hungry public likes meat best of all is shown by the fact that more than 15,000,000 pounds of meat, costing approximately \$3,500,000 is consumed annually in railway dining cars contrasted with approximately \$155,000 for

meats in the largest hotel in the world. Mr and Mrs. Traveler also enjoy their coffee and tea, using annually approximately 1,000,000 pounds of coffee and about 250,000 pounds of tea.

Keeping the dining car service supplied with milk is an enormous job not only because of the quantity used but also because it must always be fresh. Dining cars attached to transcontinental trains must be supplied with fresh milk at various points en route. This means that milk must be waiting at the station when the train arrives, for a train cannot be delayed because the milk man has overslept or is otherwise late in arriving. Approximately 3,500,000 quarts of milk and cream are used annually in dining cars.

Eggs also play an important part in the diet of the traveling public. An average of 2,000,000 dozen eggs is used annually. The bread bill of the railroads also is a sizeable amount, an average of 1,125,000 loaves of bread and 30,000,000 rolls being served each year, upon which 2,000,000 pounds of butter are spread.

More than three thousand acres of farm land are required to grow the 9,000,000 pounds of potatoes which the dining car service of the railroads require each year. The other fresh vegetables, together with the berries and fruit that are used, would make a young mountain. Fif-

diately consulted officials of the London and North Eastern Railway. He knew that some months before, that railroad had moved an entire farm, including house furnishings, wagons, agricultural implements and machinery, and livestock, a distance of 92 miles in a single day! It might be able, he thought, to solve even the Captain's problem, of how to live in Somerset County in a house that was in Suffolk County!

"Between the Captain, the builder, and the railroad, the old house was carefully demolished, and seventeen carloads of bricks and masonry, fruit trees, bins and outhouses, to say nothing of four large container cars of furniture, left Ipswich Station, on the London and North Eastern, for South Cheriton in Somerset. There Brooks Hall rose again, beam and brick by brick, a reincarnation in masonry, disappearing from Suffolk, coming to mellow life again, magically, in Somerset!"

Georgian Mansion Crosses England

A British railroad recently played the good fairy, and whisked an entire Georgian mansion across England in a few hours, in what is said to be the most ambitious moving feat ever attempted, according to T R Dester of the Associated British Railways

"Captain Schreiber, retiring chief constable of Ipswich, in Suffolk County, loved Brooks Hall, his fine, old red-brick Georgian mansion at Ipswich, and had determined to spend his leisure years in it," Mr Dester explained. "But he loved Somerset County with equal intensity and could conceive of no other place so desirable for his years of retirement. And, fatally it seemed to him, the mansion and the county of his choice were separated by the whole breadth of England To bring them together seemed hopeless Such things didn't happen outside the pages of Sir Thomas Malory or Hans Christian Andersen

"But an enterprising builder, named West, heard of the Captain's quandary, and imme-

several doctors and families enjoying the hospitality of this place.

A LONG LIST of physicians have been reported as registered at the Hotel Lexington in New York City during the month of October. Those from this state and vicinity included, Dr J A Lane, Dr R A Sauter, Dr Chas F Howland, Dr Walter J Riley, Dr J F Henggan, Dr R F Kreuger, Dr Edw Kivovits, Dr H L Bueno, Dr J L Golly, Dr Wm F Nealon, Dr J C Younie, Dr A M Crance, Dr John E Shay, Dr F R Daniels, Dr J Prescott Brown, Dr Mathew Shapiro, Dr A J Sullivan, Dr R L Strong, Dr H L MacCurdy, and many others from all parts of the United States.

THE SENATOR at Atlantic City had the following doctors registered: Dr and Mrs Harold J Isaacs, of New York, Dr and Mrs A Blank of New Jersey, Dr T Starch of New York, Dr B E Shettles of New York, Dr and Mrs M Cinader of New York, as well as many from other parts.

NEW YORK DOCTORS registered at the Book-Cadillac Hotel in Detroit recently included J H Frazer, Dr E. M Tracy, Dr Samuel J Stabins, Dr Frank Miller, Dr T S Blair, Dr Alfred Wyss, Dr Harvey L Daiell, Dr Daniel Kallan, Dr J B Condon, Dr W E Weiss, Dr D Roger Haggerty, Dr I Fresner, and many others from all parts of the country and world.

IMPORTANT archaeological discoveries have been made at Jarlshof, in the Shetlands, an island that is believed to have been a Scandinavian settlement before the Bronze Age. Many interesting objects have been unearthed, including some peculiarly shaped weights, a long narrow stone with a tree rune incised on it, a large knife-blade of iron, a pot cleek of bronze, fragments of crude vessels made of hard pottery, and small bronze sheets of scale formation. Articles older than the Bronze Age were found under a deep bed of sand.

These excavations have been carried out by the Ancient Monuments Commission. Investigations have also been made in Mousa Island by Dr Jan Petersen, director of the Museum at Stavanger, Norway.

Mousa is regarded as one of the best preserved Teutonic fastnesses in Europe. It has a circular site, about 50 feet in diameter, and is built of middle-sized schistose stones firmly cemented together. Dr Petersen's opinion of the discoveries at Jarlshof is that they point to a settlement resembling Viking dwellings in Norway.

Safeguarding Public Health is a SACRED Trust

BY BETTY LOU WILLIAMSON, R.N.

The more that the public becomes hygiene minded, the more they know about keeping clean—just plain downright cleanliness—the better citizens they become.

They think better and bigger thoughts, they work better and they accomplish greater results. They become open minded and receptive to higher standards of living and they make greater progress.

The Nu Bidet is a definite and forward step in that direction. Its use is a liberal education in personal cleanliness self respect and higher ideals.

If you but realize it, the Nu Bidet is as necessary to personal hygiene and general cleanliness, in every home, hospital and public institution, as a bathroom or a tooth brush.

The Nu Bidet is a most advanced step in the safeguarding of public health. You owe it to yourself and the position you hold to know all about it. Use the coupon now.

WHAT IS THIS NU-BIDET? READ THIS!

The Nu Bidet is a thoroughly modernized Sitz Bath and more. The following uses make it a safeguard to health and as necessary to personal hygiene as your tooth brush or the bathroom itself.

Sitz Bath for personal hygiene and treatment of rectal disorders. Spray for some purpose and feminine hygiene. Attachment for douche, enema and hydrotherapeutics entirely eliminating the old rubber bag method.

The Nu Bidet can be installed on any standard size toilet bowl in less than two hours. It will convert the ordinary bathroom into one that is truly hygienic at a small investment. Use coupon now.

We can now make Immediate Deliveries

The Nu Bidet lifts up and stands against the lid when not in use.

The Nu Bidet looks like the average toilet. No extra space required.

Nu Bidet is a complete unit of seat, Nu Bidet and lid in one, which replaces the regular seat and lid. It is with a specially designed and patented vacuum and also a specially designed venturi siphon breaker, each siphonage or a cross connection impossible.

The Nu Bidet

ACID RESISTANCE

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

On Request

A WORTHY ADDITION TO THE FINEST REFERENCE SHELF

Here, in this 80 page booklet, offered free to physicians on request, is a rich yield of clinical evidence—truly, a worthy addition to the finest reference shelf!

Creating widespread interest among physicians everywhere, this enlightening document—a reprint from the Bulletin of the Johns Hopkins Hospital of "Calcium and Phosphorus Studies" by Shelling and Hopper—it tells us, among other things of vital import

"In 134 cases of active rickets

mild cases healed within one and one-half to two months even on small or moderate doses of viosterol, whereas severe cases healed completely only after three to five months of therapy. The average duration required for complete healing in the entire group, comprising all degrees of rickets was 37 months."

The findings are based on six years' clinical experience with Viosterol preparations in the prevention of rickets, tetany and allied diseases

VIOSTEROL

is produced with the most complete background of research and control, and is identified by the names of these five eminent American pharmaceutical companies ABBOTT, MEAD JOHNSON, PARKE-DAVIS, SQUIBB, WINTHROP

Allies

in the conquest of syphilis

MOST AUTHORITIES on the subject of syphilis agree that maximum curative effects are obtained when an arsenical and a heavy metal are used alternately and continuously for a period of from twelve to eighteen months

Two products by the House of Squibb—Iodobismutol with Saligenin and Neoarsphenamine—are effective allies in the treatment of syphilis. Neoarsphenamine Squibb is characterized by its rapid and ready solubility, high spirocheticidal power and low toxicity. Also available under the Squibb label, and equally effective when conditions indicate their use, are Arsphenamine and Sulpharsphenamine.

Iodobismutol with Saligenin is offered as a product suitable for obtaining all of the systemic effects of bismuth in the treatment of syphilis. It presents bismuth largely in anionic (electro negative) form. It is slowly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated and very effective in both early and late syphilis.

Iodobismutol with Saligenin is a propylene glycol solution containing 6 per cent sodium iodobismuthite, 12 per cent sodium iodide and 4 per cent saligenin (a local anesthetic).

An Index of Brains...

As a writer has expressed it

"The most impressive and complete proof which can be asked of the tremendous power and immense value of advertising is the fact that the business standing of nations corresponds closely to their use of commercial and industrial publicity"

In other words a nation's energy, ability, industry—in short its brains—may be gauged by its advertising. In the greatest nations and the great cities you will find advertising playing a leading part. In weak and small nations and cities you will find little of it.

But nations and cities are no more than groups of people. Rich nations, rich cities, mean rich people. Advertising has plainly helped to make them so. They use it in selling and buying, too, for advertising tells them where they can buy to the best advantage.

Successful people are the ones who know how to make advertising serve their needs. In the advertising section of this issue, will be found many products you might use—*perhaps many you should use!* You can't tell unless you scan the pages carefully.

IN VOMITING OF INFANTS

KNOX GELATINE

REDUCES MILK CURD TENSION 50%

With gelatine, soft flocculent milk curds

Without gelatine, hard, indigestible milk curds

KNOX
SPARKLING
GELATINE

ONE per cent of Knox Gelatine added to the formula reduces milk curd tension over 50%. The curds instead of being tough and leathery, are emulsified—made softer and finer. This is an obvious advantage in vomiting.

Colloidal Protection—Knox Gelatine has an effective colloidal action. It helps to emulsify ingested fats. Gelatine also serves as a protective agent when combined with fruit juices or with strained and raw foods.

Growth Promotion—Knox Gelatine contains 85% of easily digested and assimilated protein, rich in lysine—a growth-promoting amino acid. Thus, it is a valuable supplement to the protein content of the diet.

Knox Gelatine is made as carefully as an ampule solution, surpassing in all respects the minimum U. S. P. requirements, pH about 6.0, contains no carbohydrates, bacteriologically safe.

Formula for Modification of Milk with Knox Gelatine

Sprinkle two envelopes of Knox Gelatine on 4 ounces of cold water. Allow to soak for ten minutes. Add 6 ounces of boiling water and stir until dissolved. Add 20 ounces of milk and 1½ ounces of carbohydrate.

Send for this new, pertinent booklet. Mail coupon today.

Accepted Products

Products Which Stand Accepted by the Committee on Foods or by the Council on Pharmacy and Chemistry of the American Medical Association

"Is This Product Council-Accepted?"

This is the first question many physicians ask the detail man, when a new product is presented

If the detail man answers, "No," the doctor saves time by saying, "Come around again when the Council accepts your product"

If the detail man answers, "Yes," the doctor knows that the composition of the product has been carefully verified, and that members of the Council have scrutinized the label, weighed the evidence, checked the claims, and agreed that the product merits the confidence of the physician. The doctor can ask his own questions, and make his own decision about using the product, but not only has he saved himself a vast amount

of time but he has derived the benefit of a fearless, expert, fact-finding body whose sole function is to protect him and his patient

No one physician, even if he were qualified, could afford to devote so much time and study to every new product. His Council renders this service for him, freely. Nowhere else in the world is there a group that performs the function so ably served by the Council on Pharmacy and Chemistry and the Council on Foods

Mead Johnson & Company cooperates with both Councils, not because we have to but because we want to. Our detail men can always answer you, "Yes, this Mead Product is Council-Accepted" —Adv

**KEMP'S
SUN-RAYED
IS BEST
-IT'S NEVER
THIN OR
WATERY**

• KEMP's delicious

Sun-Ray'd tomato juice has a background of particular significance to doctors. Originally developed for infant feeding, this juice made by Kemp's exclusive process (U S Pat 1746657) from the tender solids of whole vine ripened tomatoes, has a higher proved Vitamin A and C potency than thin, watery juices where only a part of the tomato is used. Has a finer flavor smoother consistency richer, non-separating, red ripe color

• Kemp's Sun Rayed Tomato Juice is available at practically all chain and independent food stores. Write at once for free copy of Steenbock Report on Feeding Tests, J-36, The Sun-Ray'd Company, Frankfort, Indiana

IN MEDICINE

Every physician's aim in his practice is to reduce the element of chance to a minimum. In ampule medication, the administrant has to be positive that the product is effective and uniformly consistent in dosage and quality.

Cheplin's products have lived up to the test of time in many well known hospitals and institutions—as well as in the offices of practicing physicians. Highly skilled technical staff, location, modern equipment and methods, are the elements that make Cheplin's products safe, effective, and dependable.

Samples, catalogue, and prices are yours for the asking.

ACIDOSIS *or* ALKALOSIS?

prescribe KARO

ACIDS galore are normally formed in the body and eliminated—carbonic, lactic, phosphoric and sulphuric. They are almost completely neutralized by base from cells, intercellular fluids and blood plasma. The body fluids thus maintain the normal faint alkalinity of pH 7.4.

But the defensive mechanisms of the body capable of preventing changes in reaction may be deranged in disease with consequent acidosis or alkalosis. Acidosis is associated with hyperpnea, diarrhea, dehydration, anoxemia, circulatory or renal insufficiency, alkalosis with excessive breathing, vomiting.

Treatment of acidosis is designed primarily to correct the underlying cause. In most types, fluids and fruit juices with Karo are forced every hour. In cases associated with ketosis (except where it is a disturbance in carbohydrate metabolism, as in diabetes mellitus) 20% dextrose is given intravenously at repeated intervals. In case of diabetes, insulin is given, by some authorities, simultaneously one unit for each gram of dextrose, until the condition is controlled.

Treatment of alkalosis depends upon the cause. The most common variety in children is that resulting from prolonged vomiting with loss of acid, salt and body water. No food is given by mouth except fluids with Karo, and saline intravenously. If alkalosis is the result of alkali administration in the presence of nephritis with poor kidney excretion of salts, large amounts of fluids with Karo will favor excess base elimination. Alkalosis from excess alkali administration is alleviated by forcing fluids with Karo.

In both acidosis and alkalosis, Karo is a carbohydrate of choice in the emergency of treatment. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), not readily fermentable, rapidly absorbed and effectively utilized.

CAUSES OF ACIDOSIS	
EXCESSIVE ACID FORMATION	
<i>Acid</i>	<i>Disturbance</i>
Aceto acetic	Starvation
B hydroxybutyric	Cyclic vomiting
	Diabetes
	Ketogenic diet
	Asphyxia
Lactic	Intestinal intoxication
	Respiratory failure
	Shock
	Burns
DEFECTIVE ELIMINATION	
<i>Metabolite</i>	<i>Disease</i>
Phosphate	Nephritis
	Emphysema
Carbonic acid	Respiratory obstruction
	Myocardial failure
	Narcosis

CAUSES OF ALKALOSIS	
EXCESSIVE LOSS OF ACID	
	Hyperventilation
	Tetany
	Cerebral lesions (respiratory center)
	Hysteria
	Excessive crying
CO ₂	Vomiting
	Pyloric stenosis
	Intestinal obstruction
HC ₁	
EXCESSIVE INTAKE OF ALKALI	
NaHCO ₃	In Pyelitis
	In Nephritis

MATTRESS TICKING AND BEDDING

SANITIZED TICKINGS are distributed thru GOLDING BROS CO, Inc., of New York and are identified with the products of —

U S Cabinet Bed Co (Local Distributors), Mfgs of "Eclipse Sleep Products"
Spear & Co "Spear's"
Ludwig Baumann "Ludwig Baumann"
J Michaels, Inc "J Michaels", Brooklyn
Namm's Brooklyn
Montgomery Ward "Wards"
Sears Roebuck & Co "Sears"
Sleeper, Inc "Perfect Sleeper"
and many other organizations of national reputation

The Unusual Qualities of SANITIZED Mattress Ticking recommends it to the Profession for Hospital Use

SANITIZED Tickings are identified by the following claims

- ★BACTERIOSTATIC — ACTIVELY ANTISEPTIC — Antiseptic elements are processed directly into the fabric.
- ★STERILE — More correctly termed "Having Self-Sterilizing Potency," moisture or exudates activating the process elements, when and as ACTUAL contact is established
- ★DERMATOLOGICALLY SAFE — Excerpt from laboratory report of chemical analysis with reference to foreign toxic or irritant substances

ALKALIES	Free Hydroxides	None
	Free Carbonates	None
ACIDS	Free Mineral Acids	None
	Free Organic Acids	None
HEAVY METALS	Arsenic, Lead, Mercury	None
	Antimony, Tin, Zinc, Chromium	None

after a test of 72 hours no sign of skin irritation or
redness appeared on two individuals who were subjected to the
Patch test.

SANITIZED TICKINGS are to a limited extent deodorizing

SANITIZED features are permanent and they are processed to meet a definite Antiseptic and Sterility Test Standard which is based upon methods employed by the U S Government

SANITIZED TICKING SAMPLES and Test Standards may be obtained gratis by the profession

SANITIZED TICKINGS have been subjected to numerous investigations by authorized and qualified laboratories, copies of reports are available upon request

PNEUMONIA

Prevention, Management, and Serum Treatment

RUFUS COLE M D *New York City*

It is not necessary to emphasize to this audience the importance of pneumonia as a public health problem. At present we can only guess at morbidity rates. Even death rates from lobar pneumonia are very unreliable, since the distinction between lobar and bronchopneumonia is not sharply made. There is no doubt, however, that it is the most important cause of death among the acute infectious diseases. From this standpoint, meningitis, poliomyelitis, and the acute infectious diseases of childhood are insignificant. It even kills more persons than tuberculosis. Cancer and the chronic degenerative diseases, heart disease and nephritis, only, exceed it in lethal effects.

In 1904, alarmed at the seriousness of the death rate from acute respiratory diseases, the Board of Health of New York City appointed a committee of the most distinguished physicians and pathologists to carry on investigations concerning this subject. Their report contained valuable scientific information, but gave no information offering hope of a solution of the problem.

During the intervening years a large amount of work has been done bearing on the etiology and nature of the disease. The death rate, however, has not been markedly altered and the question now confronting us is whether all this increased knowledge offers no prospect of further reducing the ravages of this plague, or leaves us as helpless as we were over thirty years ago.

At that time stress was laid upon certain so-called predisposing factors in the

etiology of pneumonia, such as chilling or exposure to cold, fatigue, and overindulgence in alcohol, and efforts have been made to lessen the incidence of pneumonia by calling attention to these factors and advising that precautions be taken to guard against them.

These precautionary measures, if they were generally observed, might have some effect, but definite information regarding their importance is very meager, and it is almost axiomatic that for public health measures to be effectively enforced, they must have a sound scientific, not a purely theoretic, basis. It is frequently assumed that an important reason why pneumonia is more prevalent here than in certain European countries is that our houses are overheated and poorly ventilated. We have no actual evidence, however, that this is a fact, and without this evidence it is impossible to change long established customs.

An important fact that has emerged from the experience with pneumonia in more recent years, is that even lobar pneumonia is rarely a primary disease. The experience during the World War showed what an important part an infection like measles might play in increasing the incidence of pneumonia, for in many of the cases of pneumonia associated with or following measles the pathological changes in the lungs resembled those occurring in lobar pneumonia, and in a large proportion of the cases the bacterial infectious agent was pneumococcus. Also, during the great epidemic of influenza, while many of the cases of pneumonia oc-

curing at the time were found to be streptococcal in origin, in certain places, at least, cases of pneumonia of a lobar type and due to pneumococci occurred in large numbers. At least, during this period the incidence of true lobar pneumonia greatly increased. Moreover, it has become increasingly evident that most cases of lobar pneumonia give a history of preceding symptoms referable to the upper respiratory tract. A review of our histories shows this sequence of events in over sixty per cent of the cases, and the number would undoubtedly be much larger had this matter been carefully investigated in all instances.

It is very tempting to conclude from this that pneumonia may be considered to be a complication of preceding coryza or influenza, epidemic or sporadic. It must be borne in mind, however, that pneumonia chiefly prevails during the season when colds are also prevalent. Duell has found from careful studies that on an average every individual suffers from one to three colds annually. Nevertheless, it appears that a close association of some kind exists between the occurrence of coryza or more severe upper respiratory infections and the onset of lobar pneumonia, and it is probable that if methods were available for the prevention of these infections of the upper respiratory tract, the incidence of pneumonia would at the same time be decreased. Of much significance as regards the prevention of pneumonia, therefore, has been the recent presentation of evidence that common colds and influenza are specific infections caused by filterable viruses.

Dochez and his collaborators have demonstrated that following the transfer of nasal washings from persons suffering from colds to healthy individuals the latter may exhibit all the features of coryza. They have demonstrated that this occurs even though the washings be first passed through filters so fine as to hold back all bacteria. They have also shown that when the washings are added *in vitro* to certain media containing living cells, apparent multiplication of the infectious material occurs. The collection of the evidence so far obtained, however, has been extremely difficult since only man himself and anthropoid apes have

been found to be susceptible. Since there is apparently little immunity following an attack of the natural disease, the production of artificial immunity to this virus may be very difficult. Moreover, it is possible that there is not merely one cold virus but there may be many. But the important fact is that the ground has been broken, a start has been made.

So, too, an important advance has recently been made regarding the more serious upper respiratory disease—influenza. In the past it has been exceedingly difficult to define this clinical condition. During the great epidemics, such as that which prevailed in 1918-19, the cases diagnosed as influenza exhibited considerable uniformity. During the interepidemic periods, there occurs not only small localized outbreaks of a disease resembling the epidemic disease, but every physician every year sees a considerable number of isolated cases in which similar symptoms are present. However, in many of these cases the symptoms differ from those present in common colds only in their severity.

The study of the cases in the great epidemic brought no conclusive knowledge concerning the etiology. Three years ago Laidlaw and Andrewes, in England, during the study of certain patients suffering from conditions diagnosed as influenza, instilled nasal washings from these patients intranasally into ferrets, with the result that in these animals fever developed, not infrequently lesions in the lungs appeared, and in certain instances the animals died. The infection could be transmitted by bacteria-free material through a series of animals. In this country, also, Francis studied material obtained from small epidemics of so-called influenza in Puerto Rico and Alaska and from isolated cases in New York and Philadelphia, and was able similarly to produce a transmissible disease in ferrets. This infectious material could also be filtered, and later it was possible to transmit this filterable virus in cell-containing media and with the cultures reproduced the disease in animals. The evidence seems fairly conclusive, therefore, that influenza, at least that of the interepidemic periods, is also due to a filter-

The relation of this influenza virus to the cold virus is still uncertain, and it is not yet established that there is only one influenza virus, although apparently all the viruses obtained in 1934 by Francis from widely different sources are immunologically identical, and also the same as that obtained in England. Francis has also been able to develop methods for the artificial immunization of man against the 1934 virus. Through experiments carried out first on himself and then on volunteers, he found that the virus when injected subcutaneously was quite harmless. He therefore, in a group of men, made repeated subcutaneous injections of the culture virus, and when the blood of these individuals was studied later, it was found to have high protective power. So far as can be determined by this technic, therefore, it is possible to immunize man against this virus. How long this immunity lasts is impossible at present to say, and whether a method is available to prevent the occurrence of epidemic influenza and possibly of sporadic cases is too soon to predict.

But in any case, some progress has been made in understanding the acute upper respiratory infections that so often seem to be precursors of lobar pneumonia, and it is possible that the development and application of this knowledge may in the future be of great significance in the prevention of pneumonia.

But whether pneumonia is preceded by some other infection or not, the lung lesions and the severe symptoms are undoubtedly due to bacterial invasion. As is well-known, however, any one of a great number of bacteria may produce acute inflammation of the parenchyma of the lungs, which is what is really meant by pneumonia. This term, therefore, from the etiological point of view includes a great number of diseases. It is analogous to the term which a hundred years ago was used to describe all acute abdominal conditions, at that time typhoid fever, paratyphoid, appendicitis, peritonitis, and the various forms of dysentery were all designated "acute inflammation of the bowels."

The discovery of the methods of percussion and of auscultation and the invention of the stethoscope by Laennec led to a better knowledge of acute lung disease,

and the development of pathological anatomy was followed by the differentiation of cases of pneumonia on a purely anatomic basis into cases of bronchopneumonia and cases of lobar pneumonia, depending on whether entire lobes or only portions of the lung structure were involved.

While this was of some value from the clinical standpoint, as regards epidemiology or prevention or specific treatment, this kind of differentiation has been of little use. Indeed, these terms are very confusing, for with the tissues before him the pathologist is frequently unable to say whether the condition present in the lung should be called lobar or bronchopneumonia.

At the present time it seems much more useful to limit the term "lobar pneumonia" to cases associated with the presence of pneumococci, and for all the other cases of acute pneumonia—those due to streptococcus, staphylococcus, Friedlander's bacillus, etc.—to employ the term "atypical pneumonia." This is also not a good designation, but I know of no better one.

But, as you all know, even the cases of lobar pneumonia are not all due to a single etiologic agent. The types of pneumococci which have been described are now so numerous that only the specialist can keep track of them. But the discovery that pneumococci are not all alike but that there are a number of types, each differing from the others specifically in immunological character, has been of great significance, for it has cleared up many points regarding the epidemiology of the disease, which before were quite obscure, it has revealed possibilities for prevention, and it has made serum treatment possible in at least one group of cases.

Fortunately, so far as simplicity in prevention and treatment is concerned, the majority of cases of lobar pneumonia are due to pneumococci of two types, I and II. The relative frequency of occurrence of cases due to the different types undoubtedly differs somewhat in different places and at different times, but in general one may say that thirty-five to forty per cent of all cases of lobar pneumonia are due to Type I pneumococci and twenty-five to thirty per cent are due to Type II organisms, that is, sixty to seventy per cent

curring at the time were found to be streptococcal in origin, in certain places, at least, cases of pneumonia of a lobar type and due to pneumococci occurred in large numbers. At least, during this period the incidence of true lobar pneumonia greatly increased. Moreover, it has become increasingly evident that most cases of lobar pneumonia give a history of preceding symptoms referable to the upper respiratory tract. A review of our histories shows this sequence of events in over sixty per cent of the cases, and the number would undoubtedly be much larger had this matter been carefully investigated in all instances.

It is very tempting to conclude from this that pneumonia may be considered to be a complication of preceding coryza or influenza, epidemic or sporadic. It must be borne in mind, however, that pneumonia chiefly prevails during the season when colds are also prevalent. Duell has found from careful studies that on an average every individual suffers from one to three colds annually.

Nevertheless, it appears that a close association of some kind exists between the occurrence of coryza or more severe upper respiratory infections and the onset of lobar pneumonia, and it is probable that if methods were available for the prevention of these infections of the upper respiratory tract, the incidence of pneumonia would at the same time be decreased. Of much significance as regards the prevention of pneumonia, therefore, has been the recent presentation of evidence that common colds and influenza are specific infections caused by filterable viruses.

Dochez and his collaborators have demonstrated that following the transfer of nasal washings from persons suffering from colds to healthy individuals the latter may exhibit all the features of coryza. They have demonstrated that this occurs even though the washings be first passed through filters so fine as to hold back all bacteria. They have also shown that when the washings are added *in vitro* to certain media containing living cells, apparent multiplication of the infectious material occurs. The collection of the evidence so far obtained, however, has been extremely difficult since only man himself and anthropoid apes have

been found to be susceptible. Since there is apparently little immunity following an attack of the natural disease, the production of artificial immunity to this virus may be very difficult. Moreover, it is possible that there is not merely one cold virus but there may be many. But the important fact is that the ground has been broken, a start has been made.

So, too, an important advance has recently been made regarding the more serious upper respiratory disease—*influenza*. In the past it has been exceedingly difficult to define this clinical condition. During the great epidemics, such as that which prevailed in 1918–19, the cases diagnosed as *influenza* exhibited considerable uniformity. During the interepidemic periods, there occurs not only small localized outbreaks of a disease resembling the epidemic disease, but every physician every year sees a considerable number of isolated cases in which similar symptoms are present. However, in many of these cases the symptoms differ from those present in common colds only in their severity.

The study of the cases in the great epidemic brought no conclusive knowledge concerning the etiology. Three years ago Laidlaw and Andrewes, in England, during the study of certain patients suffering from conditions diagnosed as *influenza*, instilled nasal washings from these patients intranasally into ferrets, with the result that in these animals fever developed, not infrequently lesions in the lungs appeared, and in certain instances the animals died. The infection could be transmitted by bacteria-free material through a series of animals. In this country, also, Francis studied material obtained from small epidemics of so-called *influenza* in Puerto Rico and Alaska and from isolated cases in New York and Philadelphia, and was able similarly to produce a transmissible disease in ferrets. This infectious material could also be filtered, and later it was possible to transfer the infection to mice. He also cultivated this filterable virus in cell-containing media and with the cultures reproduced the disease in animals. The evidence seems fairly conclusive, therefore, that *influenza*, at least that of the interepidemic periods, is also due to a filterable virus.

course, only be surmised. The studies of Smillie indicate that the spread of the infectious agent to contacts is facilitated if the latter have colds.

Formerly it was believed that the occurrence of disease in an epidemic form was largely dependent upon an increase of virulence of the infectious agent. The careful investigation of epidemics artificially induced in laboratory animals by Topley in England and by Webster and others in this country have cast much doubt on this hypothesis. The data available at present seems to indicate, as Webster has stated, that the prevalence of disease in any population group "is controlled by fluctuation in the dosage of, and resistance to, specific agents of relatively fixed character." The experience so far obtained indicates that this statement probably also applies to Type I and Type II pneumonia. The indications are that the average person possesses fairly high resistance to infection with pneumococci and that it is only when the dosage is very high or when resistance is lowered that infection occurs.

Now if pneumococci of Types I and II are not widely distributed in nature, and if infection occurs chiefly through contact with persons ill of the disease, it is obvious that spread of the infection might be controlled by isolation of these patients. The mode of spread of infection in pneumonia due to pneumococci of the other types is not so clear, but as regards these two particular types the evidence now seems sufficiently convincing to justify careful isolation of the patients and thorough cleaning of rooms in which these patients have been treated.

Fifteen years ago we began to isolate all pneumonia patients admitted to the Hospital of the Rockefeller Institute, and the doctors and nurses and all persons coming in contact with them have been required to wear gowns and face masks. While the use of masks may not have great usefulness in preventing the spread of the infectious agent, those precautionary measures have had much educational value by laying stress on the fact that we are dealing with specific infectious diseases.

Smillie found that, although a very large proportion of individuals coming into contact with pneumonia patients in

the house became carriers of infection, few of the doctors or nurses or patients in adjoining beds in hospitals did so. He concluded from this that "it is quite justifiable to treat cases of lobar pneumonia due to Type I or Type II pneumococci in the open wards of our general hospitals." The contrast in the conditions found in the home and in the hospital may probably be explained by the fact that in most modern hospitals, through constant cleaning, removal of dust, etc., conditions exist which practically amount to partial isolation. Moreover, ordinarily colds and coryza, which facilitate spread of infection, do not prevail in general wards. However, Smillie himself describes an instance where one of the physicians became infected through close contact with a patient suffering from Type I pneumonia.

Just how important a result may be achieved by isolation of patients with pneumonia cannot be foretold, but it is probable that if isolation could be carried out in all cases, the incidence of Type I and Type II pneumonia could be markedly reduced. The conditions as regards Type I and Type II pneumonia are not greatly unlike those in typhoid fever. Although other more practical public health measures for preventing typhoid fever were later discovered, it was amply demonstrated in several communities that the prevalence of this disease could be very greatly diminished by isolation of the patients and destruction of the excreta.

What could be accomplished in the prevention of pneumonia by the method of artificial immunization is still questionable. As I have previously stated, man is probably relatively quite resistant to infection with pneumococci. The nature of his basic underlying resistance, however, is still obscure. This is not so strange, since it is not known why guinea pigs are very resistant, and mice and rabbits are extremely susceptible to pneumococcal infection.

Blake has presented some clinical and experimental evidence suggesting that in man the basic resistance to pneumococci is not type specific but species specific, and it is true that in most individuals type specific immune substances cannot be demonstrated in the blood. It is possible, indeed, that natural resistance is entirely

of all cases of lobar pneumonia are associated with pneumococci of these two types. The great public health problem, therefore, relates to the control of these cases.

For many years, the fact that pneumococci are frequently present in the mouths of healthy individuals as well as in the mouths of those suffering from pneumonia, caused doubts to be raised concerning the etiologic relation of these bacteria, and even after the pathogenicity of pneumococci was fully demonstrated, made the formulation of any conception of the epidemiology of pneumonia well-nigh impossible. Following the demonstration of type differences, however, it was found that pneumococci of Types I and II can rarely be isolated from the mouths of healthy individuals, and when they are present it is usually found that the individuals harboring them have lately been closely associated with persons suffering from pneumonia due to pneumococci of the same type. For instance, Webster, in a group of 105 healthy individuals from whom over 3,000 cultures were made over a long period of time, found Type I pneumococci in only a single individual, and then only once, and Type II organisms only on three occasions in two individuals. Similar observations have now been made by many others. On the other hand, when cultures are made from persons closely in contact with patients with pneumonia, organisms of the same type as those causing the disease are not infrequently present. Thus Smilie, in studying the house and family contacts of persons suffering from Type I or Type II pneumonia, found in the case of Type I contacts, organisms of the same type present in about one-fourth of the persons examined, and in the case of Type II contacts he found these organisms in over sixteen per cent of the contacts. It has been found, however, that pneumococci of these two types do not persist in the mouths of these healthy persons, but that in most cases they disappear within a short period of time. There may be chronic carriers of these organisms, but they are not numerous. Stillman was also able to cultivate from the dust and surroundings of pneumonia patients pneumococci of the same type as those causing the disease. The evidence, however, indi-

cates that these bacteria are not highly resistant to conditions present outside the body, though on one occasion Stillman found pneumococci of Type I in dust collected in the hallway of a tenement house in which forty days before there had been present a case of pneumonia of this type. Similar bacteria could not, however, be cultivated at this time from the dust of the patient's room, and it is possible that the presence of Type I pneumococci in the dust of the hallway was due to a chronic carrier living in the building. At any rate, most of the evidence indicates that pneumococci of these particular types are present chiefly in patients suffering from the disease, or in persons closely in contact with them, and in the immediate surroundings of these patients, and that these organisms do not persist for long periods of time except in the presence of disease. That these diseases may spread by contact infection from the ill to susceptible individuals has been shown by the fact that when two or more cases of pneumonia occur in members of the same family, as sometimes happens, all of the cases in most instances are due to pneumococci of the same type. Moreover, a limited number of small epidemics of lobar pneumonia in institutions or in small neighborhoods have now been investigated, and pneumococci of identical type have been demonstrated in all the cases.

An interesting epidemic of lobar pneumonia in a small village of three hundred inhabitants in Germany has recently been studied by Gundel. Within a period of a little over a month, ten per cent of the inhabitants became ill with Type I pneumonia. The studies showed that the epidemic started in a group of children who were closely associated in the school. By means of nose and throat cultures the spread of the infection could be traced. Finally one-third of the villagers became carriers of Type I pneumococci. It is probable that the rapid spread of the disease was due to the fact that the inhabitants of this isolated village had previously had little contact with this form of infection and were relatively highly susceptible. Milder forms of upper respiratory disease were also prevalent at the time. What influence this had on the occurrence of the pneumonia can, of

this might seem to be a matter to be discussed by physicians and to have no place in a public health program. However, public health authorities must become interested when therapeutic measures require the employment of technics and kinds of organization which are inaccessible to the practising physician. As you know, in New York State under the auspices of the State Medical Society, the State Board of Health, and certain private agencies, a campaign is now under way to improve the treatment of pneumonia by giving aid, instruction, and support to physicians employing serum treatment. Twenty years ago, following the demonstration that pneumococci are not all identical but that there are a number of distinct immunological types of pneumococci, and that animals suffering from pneumococcal infections could be cured by the administration of specific immune serum provided it was given early enough after the onset of the infection and provided it were administered in sufficiently large quantities, we began at the Hospital of the Rockefeller Institute to treat cases of Type I and Type II pneumonia, giving intravenously doses of immune serum that were then considered to be of extraordinary size. To give patients one hundred c.c. of horse serum intravenously was then thought to be dangerous, and by many was thought to be unjustifiable. However, in the light of the experimental evidence and in spite of much doubt and criticism on the part of many in the medical profession, we persisted. After a little experience it became evident that the results in Type I pneumonia were excellent, but in Type II pneumonia less encouraging. The employment of Type II serum was then discontinued. For the past twenty years practically all cases of Type I pneumonia admitted to the Hospital of the Rockefeller Institute have received large doses of immune horse serum. Fortunately the day seems to have passed when it was necessary to urge the value of this form of treatment. Most of the skeptics have become convinced, some of them in our opinion have even become somewhat overenthusiastic.

Although it seems probable that we now possess serum which is effective in certain of the less common types of pneumonia, and it is not impossible that in the future

modification may be found to improve Type II serum so that it may be useful at present the serum treatment of Type I cases is the only form of specific therapy in pneumonia that is on a well-established basis and the practical employment of which is now available to all physicians.

It is not sufficient, however, that patients be simply treated by the administration of Type I serum, of great importance is *how* they are treated. Before any treatment can be undertaken, the diagnosis of pneumonia must be made. Unfortunately, in the past most physicians have waited for the appearance of all the signs of consolidation before making a diagnosis. Patient after patient has been sent into our hospital with the statement that he has been suffering with severe symptoms for three, four, five, or even more days, but that the signs of pneumonia have just appeared. These patients have really had pneumonia for days, but it is quite true that the physical signs have not been definite.

The truth of the matter is that evidence of consolidation is not necessary for the diagnosis of pneumonia. To the experienced observer the symptoms of the onset of this disease are, in most cases, definite and unmistakable. In almost all cases the person who has a chill, fever over 102°, cough, pain in the side, rapid respirations, and, above all, who is expectorating sputum which is bloody, or even only slightly tinged with blood, has pneumonia. Even in persons who have suffered from cough or mild upper respiratory infections before the onset, the appearance of the more serious pulmonary infection is, in most instances, clearly indicated by the more or less sudden appearance of the symptoms I have mentioned. We physicians have made the diagnosis of pneumonia too difficult, and it is much less important that we make an occasional mistake, than that we live in fancied security for days until it is too late for effective specific treatment. Most cases "threatened with pneumonia" *have* pneumonia.

The determination of the etiologic agent in all cases of pneumonia involves difficulties, but methods are now available by means of which this can be done promptly in most instances. This is where the laboratory can be of help, and fortunately

unrelated to humeral immunity. But however this may be, we now know that even the most highly susceptible animals such as the rabbit may be rendered very highly resistant to infection with a particular type of pneumococcus by previously injecting into them killed cultures of the pneumococcus in question. Under these circumstances specific immune bodies appear in the blood.

In spite of all that has been learned concerning the artificial immunization of animals, it is somewhat disappointing that up to the present no successful use has been made of this knowledge in the prevention of pneumonia by the method of artificial immunization. One great difficulty in the way of progress in this field is the fact that owing to the endemic occurrence of this disease, and the more or less uniform distribution of cases in the population at large, the immunization of very large numbers of individuals and very careful collection of large statistical material would be required to determine whether or not the procedure were effective. Obviously, since ordinarily only three or four persons per thousand contract pneumonia, and only one or two die, judgment regarding the efficacy of the method will be difficult.

So far as I know there have only been two large scale attempts to solve this problem. During the World War, Cecil and Austin at Camp Upton vaccinated over 12,000 soldiers, leaving 19,000 unvaccinated as controls. The results, however, permitted no definite conclusions to be drawn, for while no cases of Types I, II, or III pneumonia occurred among the vaccinated troops and twenty cases developed among the unvaccinated, a very similar distribution of cases of streptococcus pneumonia occurred, 106 among the unvaccinated and only six among the vaccinated. It is difficult to understand how antipneumococcus vaccination prevented the occurrence of streptococcus pneumonia, and one cannot help drawing the conclusion that all the results were due to some other unknown factors. The experiment lasted, however, only a month and a half. It was hoped to observe the subjects over a long period, but owing to the exigencies of war this proved impossible.

The other large experiment has been

carried on over a number of years in the diamond mines in South Africa. During the period in which immunization has been employed, the incidence of pneumonia has markedly decreased, but during the same time improved hygienic conditions have been instituted and certain other factors have come into play so that it is impossible to say what part of the result, if any, has been due to the immunization.

Although the results so far have been inconclusive, the possibility remains that, if better methods were used, artificial immunization might be effective in reducing the incidence of this disease. Much has been learned during very recent years regarding the antigenic action of pneumococci and their products. The effects of autolysis and the action of ferments in rendering vaccines non-antigenic is now better understood. One of my associates has recently studied a commercial vaccine purchased in the open market and found it entirely inactive. Probably many of the vaccines previously employed have been lacking in antigenic properties. It has been shown that while in certain animals, as rabbits, the soluble specific carbohydrates have no antigenic action, in others, as mice, and in man, these substances act as true antigens. Following the intracutaneous injection of very small amounts of these substances in man, the blood acquires the property of precipitating the homologous specific substance, agglutinating the bacteria, and protecting mice against infection with pneumococci of the homologous type. If one may draw conclusions from analogous experiments in animals, these individuals have undoubtedly acquired increased resistance against infection. Moreover, it has been found that the immunity so induced may persist for a long period of time, at least two to three years. It seems, therefore, that further studies should be made of this and other methods of immunization and after the best method has been decided upon it should be tested on a large scale.

Although we now possess no well-established methods for reducing the incidence of pneumonia, there can be little doubt that the mortality from certain forms of pneumonia may be definitely decreased by specific treatment, provided this is carried out properly. At first sight

The greater ease of administration of the concentrated serum is obvious. In addition, most observers feel that the frequency of immediate reactions is less. This, however, is not certain. Anaphylactic reactions may occur with small amounts of serum as well as with large. Febrile reactions depend very much upon the care with which sera are prepared. Certain lots of unconcentrated sera give febrile reactions in a large proportion of cases, others rarely. In our experience, however, using both concentrated and unconcentrated serum from the same source, the febrile reactions with the concentrated serum have been notably less than with the whole serum. Probably the greatest value in using the concentrated serum consists in a decrease in frequency and severity of the symptoms of serum disease. These symptoms occur, however, with either the concentrated or unconcentrated serum, in at least half of the cases, seven to ten days following the administration of the serum. With present knowledge there is no way in which these unpleasant but harmless symptoms may be completely avoided. After all, in a very serious disease like Type I pneumonia, from which one patient in every four dies, a few days of itching and pain in the joints is not too high a price to pay for restoration to health. In our clinic 462 cases of Type I pneumonia have now been treated with immune serum. We have judged its value in these cases by the apparent effect on the symptoms, the fact that following its administration bacteria disappear from the blood and on the mortality rate in the patients treated.

Since, during the same period the mortality rate in cases of pneumonia not due to Type I pneumococci has remained at about the same level as that in other hospitals, it seems that the low rate in the Type I cases is definitely due to the serum treatment. In our last twenty-eight cases treated with concentrated serum, not a single patient has died, and one cannot but believe that our constantly improving results are due to the splendid serum now being prepared under the direction of Dr Wadsworth of the laboratories of the State Department of Health.

The complaint is sometimes made that after all, serum treatment is possible in

only a part of the cases of pneumonia, and attempts are made to treat all cases of pneumonia either with Type I sera or with so-called polyvalent sera. Type I pneumonia, however, in this country probably causes 25,000 deaths every year, almost twice as many as were ever due to typhoid, except in certain epidemic years. Type I pneumonia should be looked upon as a specific infectious disease, as specific as is typhoid fever, and be treated as such.

From our experience, therefore, Type I serum should be given as early as possible and in large amounts, and the doses should be repeated every four or five hours until definite effects are seen in the fall of temperature, decrease in pulse and respiratory rates, and improvement in the other signs of intoxication. If the infection is not severe, one or two doses may be sufficient, but there is no way of judging the severity of the infection at the outset, and it is useless to "feel one's way" and begin the treatment with very small doses. It is better to give too much than too little. Skin tests with soluble specific substance, as proposed by Francis, are useful in determining when sufficient serum has been given, but the observer must have had considerable experience in order to rely on this method alone. Much stress has been laid upon the possible dangers of violent reactions. There are some risks, but we now know how to guard against them. That we did not have disastrous results when we first began using very large amounts of serum intravenously, when we did not know the dangers or how to guard against them, shows that the dangers are not too great. By making preliminary tests for serum sensitiveness, by proceeding very slowly in the first injections, and by prompt use of adrenalin in case any symptoms occur, the possibilities of serious complications are almost entirely avoided.

In conclusion, one may say that, although we are still far from the final solution of the pneumonia problem, definite advances have been made and knowledge concerning the diseases of the respiratory tract have been so greatly increased during recent years that we can begin to venture the hope that means will be found to reduce the mortality from these diseases, just as the mortality from

in this state branch and approved laboratories of the State Board of Health are now so located that practically every physician can very quickly have sputum examined and obtain information regarding the type of infection present. But the physician and nurse must take pains to obtain good specimens of sputum and personally see that they are sent to the laboratory at once. By the so-called Neufeld method, all that is necessary is to treat the sputum with rabbit immune sera of the various types. If, for instance, the organisms are of Type I, swelling of the capsules occurs in the Type I serum and in sera of no other types.

In certain cases it is not quite so simple as this, but if the laboratory takes adequate pains, a diagnosis can be made promptly in almost all cases. The laboratory should consider the examination of pneumonia sputum an emergency measure. It should not be delayed until the next morning or until other work is out of the way, and the physician should be notified by telephone or telegram as soon as the diagnosis is made.

As soon as it is determined that the patient is suffering from Type I pneumonia, serum should be administered. There should be no waiting to see whether the patient will not be better in the morning, it should not be delayed because he does not seem sick enough to justify giving serum, or it should not be decided that "it is too late, he is too far gone for serum to be of any use."

The only exceptions we have made in administering serum have been in an inconsiderable number of children who were not very ill, since most children with lobar pneumonia recover, *second* in patients who were moribund on admission and died before serum could be administered, and *third* in patients who were obviously in the stage of recovery on admission.

All other cases have been treated as soon as the diagnosis was made. This is of importance because some of those employing serum have recommended that it be used only in cases that can be treated as early as the third or possibly the fourth day. It is true that the effectiveness of the serum is apparently greater the earlier in the disease it is used, but our experience indicates that no patient, however late he is seen, should be deprived of the

benefits of this measure. In our series, the mortality rate in cases treated during the first three days was 48 per cent, in those treated on the fourth day or earlier, 82 per cent, on the fifth day or earlier, 86 per cent, and in those treated after the fifth day, 195 per cent.

Until two years ago, whole serum in doses of one hundred c.c. was administered, during the past two years concentrated serum has been used. As early as 1915, Avery determined which fraction of the serum contained the immune principles, and demonstrated how concentration of the serum might be accomplished. We delayed employing concentrated serum, however, for many years, even after improved methods for concentrating the serum were devised by Felton and others, for the following reasons. In the first place, concentration adds materially to the expense of an already very expensive procedure, since in all methods of concentration a large loss of immune substances inevitably occurs. Concentrated serum contains nothing which the unconcentrated does not contain. In the second place, in our opinion the methods first employed for standardization of the concentrated serum gave entirely misleading information regarding its actual strength. With the methods first proposed, it was claimed that a concentration of twenty or more times that of the original serum had been obtained and doses of five c.c. of the concentrated serum were considered adequate. Our own observations and experience taught that this was impossible. Specific treatment in this serious disease is not one for a teaspoonful three times a day before meals.

Several years ago, when the New York State Board of Health was able to supply serum concentrated from good effective serum, and not from weak serum which would otherwise be useless, and when we could be sure that it was standardized by a satisfactory method, we began using this, not in doses of a few cubic centimeters, but in fifteen to thirty c.c. doses. That is, it has been possible to concentrate the serum three to five times. Using the determination of strength employed by the New York State Board of Health, we have used doses of 90,000 units present in amounts of fifteen to thirty c.c. of concentrated serum.

SURGICAL TREATMENT OF PERIPHERAL VASCULAR DISEASE

GEZA DE TAKATS, M D , M SURG , F.A C S , *Chicago*

Let there be but one opinion and you have an end of research and knowledge—*Aschoff*

*From the Department of Surgery, University of Illinois, College of Medicine,
Illinois Research and Educational and St Luke's Hospitals*

The success of the surgical therapy of peripheral vascular disease rests on a number of factors. Accurate diagnosis, a thorough trial of conservative management, the careful selection of the stage of the disease in which operation is undertaken, adequate postoperative treatment, and a sober evaluation of late results will bring about a crystallization of indications. It must seem obvious that the surgeon undertaking the operative treatment of peripheral vascular disease must be fully familiar with all other aspects of a peripheral circulatory disturbance or be closely associated with men interested in cardiovascular disease. Unless the natural course of the disease with its exacerbations, remissions, and periods of latency are known, a faulty evaluation of the results is apt to follow.

In this comparatively new field, a group of uncritical enthusiasts and hypercritical nihilists are arguing the merits of their pet projects and peeves. In addition, a host of gadgets, mechanical rocking chairs, oscillating beds, cradles, thermostats, vacuums, and exsiccators have appeared on the market. Small wonder that in this maze of enthusiasm and denunciation the general practitioner may readily become confused. Symposiums such as this should serve the definite purpose of summarizing advances made and outlining trends of thought.

It would be tempting to review here all the surgical procedures advocated for the treatment of peripheral circulatory disturbances, but Dr George Scupham and I have done this elsewhere.¹ Because of the limited time I will restrict this discussion to the procedures with which I have had personal experience and which have stood the test of time. These surgical procedures may conveniently be discussed under three headings, namely (1) surgical efforts to improve circulation,

(2) surgical efforts to alleviate pain, and (3) surgical methods to remove nonviable parts at the optimal time and at the optimal level.

Surgical Attempts to Improve Circulation

Embolectomy The conclusions reached from a survey of the literature and an analysis of twenty-nine cases of sudden arterial thrombosis and ten cases of acute arterial embolism are as follows:²

1 An attempt should be made to differentiate between embolism and thrombosis of the peripheral arteries, keeping also in mind the possibility of traumatic vessel spasm and venous or lymphatic block with secondary vessel spasm.

2 One must try to localize the site of occlusion and determine on the basis of the patient's age, cardiovascular status, and the known incidence of gangrene from occlusion at that site, whether or not a gangrene is to be expected.

3 It is necessary to utilize vigorous conservative measures, including heat, papaverine, and negative pressure if available, with the purpose of overcoming the spasm of collateral vessels which always accompanies sudden arterial occlusions.

4 Should these measures fail and equipment be available, an embolectomy is indicated, especially if the patient is seen within the first ten hours.

5 If all these measures fail and gangrene is present, amputation is indicated at the level of adequate circulation if there is a chance to save the patient's life.

Of the ten cases that I have diagnosed as arterial embolism, five have been explored. The other five either arrived too late or responded to conservative measures. Only two cases out of the five survived, both being cases of embolism of the iliac arteries. I am convinced that if these patients had been treated early with methods producing vasodilatation and brought to the surgeon in less

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

acute intestinal infections has been diminished. The close relation between the milder acute diseases of the upper respiratory tract and the more serious lung infections makes one believe that the most important step will consist in the prevention of colds and influenza. The important new knowledge that has been gained regarding these conditions marks a long step forward toward that goal.

Something in the way of preventing pneumonia can be accomplished by isolation of pneumonia patients and preventing the distribution of the more specific micro-organisms, Types I and II, from patients infected with these bacteria. Physicians should feel the responsibility of warning patients and friends of the danger of spreading the disease and of the importance of wearing masks and gowns and of thorough cleaning of rooms previously occupied by pneumonia patients.

Methods of immunization deserve thorough study, and after a decision has been reached regarding the procedure which offers the greatest promise,

it is hoped that it may be tried on a larger scale and over a sufficiently long period to obtain definite and conclusive results.

At the present time, a real impression can be made on the mortality rate by the general and proper use of immune serum in the treatment of Type I pneumonia. The State Board of Health is ready to assist in this matter and it now remains for physicians to make full use of this therapeutic procedure.

Consolidation of efforts by the medical profession and the health authorities offers great promise of usefulness, not only in this but in other fields. After all, the object of both groups is to diminish disease and delay death. That the members of one group should have their attention chiefly directed toward the individual and those of the other group toward society as a whole should give rise to no conflicts. The coordination of their activities should greatly increase the effectiveness of both groups. Instead of thinking of prevention or cure, we must all be interested in prevention and cure.

730 PARK AVE.

A TAKE OFF ON ALLERGY TREATMENT

A keen sense of humor can make almost anything comic, and an anonymous writer takes a crack in the *Atlantic* at the varied treatments for all the assorted kinds of allergy. His fictional characters are "Mrs Werfel" and "Dr Wattle," and the skit is neatly condensed by the Editor of the *Virginia Medical Monthly* thus:

"Expectantly," so runs the account, this allergist "produced his tray of concentrated poisons, two hundred vials containing such deadly extracts as those of the soybean, the dill pickle, kohlrabi, nutmeg, and canary feathers. Expectantly, with his tiny flat instrument, he coerced one hundred varying substances into each of Mrs Werfel's arms. At the end of the two hours which the operation consumed, her arms bloomed like the rose, but with hives."

Cheerfully Mrs Werfel was told "that she was intolerant to barley, oats, wheat, buckwheat, casaba, rice, cocoa, coffee, tea, tobacco, artichoke (French), artichoke (Jerusalem), asparagus, the navy bean, beet, broccoli, Brussels sprouts, not to mention chives, corn, cottonseed, cucumber, dandelion, parsley, parsnips, peas, pimiento, potato, pumpkin, as well as garlic, ginger, hops, malt, mustard, nutmeg, paprika, peppers, psyllium seed, sage, senna—as time went on she dozed, missing the fruit, the fish, the nut, the fabric, the feathers, the powder, the bacillus classes," and cheerfully she was instructed to confine her diet to "butter, heavy

cream, goat milk, Parmesan cheese, egg white, duck egg, goose egg, gelatin, pork, rabbit, fig, lemon, butterfish, butternut."

When jaundice reduced this diet to the starvation proportions of gelatin and butternut, Dr Wattle came to the rescue with "a really miraculous serum," which he assured her would make future dieting completely unnecessary, if she would be patient, for it naturally took time for the system to be "properly stabilized."

For three years he juggled the dosage for "extreme stimulation or extreme depression followed if the amount administered was too large or too small," and "the physician could only judge from the patient's reports," and when Mrs Werfel was ready to jump off a bridge, Dr Wattle was ready to save her with "the perfect diet, the diet that does away with all serums, the fat-free diet."

"But," said the now completely bewildered Mrs Werfel, "I thought butter and cream, according to the skin tests,

"Skin tests," observed Dr Wattle, "served their purpose for a time, but we have since discovered them to be misleading. The fat-free diet, on the other hand, is universal. Moreover, you must remember, that there is a certain type of allergy."

Then the *Virginia* editor, "at the risk of being considered utterly devoid of humor," argues at some length that "this is not the true picture of allergy in the hands of the true allergist."

and in which reflex dilation to heat produces only a slow and incomplete rise in temperature, the results are moderate but still worthwhile. The hand may become cold and arterial spasms may return but the progress of the disease is arrested and the attacks are less frequent. All patients in this group feel that they have benefited from the operation but the result is not as dramatic as in the first group.

In the third stage, patients have advanced structural disease of the arteries. The fingers will fail to heat up when heat is applied to the lower extremities. They suffer from a diffuse sclerosis of the digits involving skin, joints, tendons, a sclerodactyly secondary to an advanced Raynaud's disease. In such patients the late results are poor and a year or two after the operation the condition of the hands is no better than before. While in the first two groups the operation has been of great benefit, in the third stage it is useless.

In poliomyelitis with vessel spasm, the type of patient who will be benefited by lumbar sympathectomy has been described by Harris as follows⁶:

In a child, preferably not older than eight years, if the paralysis is limited to one extremity and is moderate in degree, a sympathetic ganglionectomy will maintain an increased vascularity of the extremity and can result in accelerated growth of the shortened limb.

Scupham and I are studying three children who have been picked from Dr. Ryerson's material out of a group of twenty-five. Our experience has been favorable in that the cold, painful, plum-colored extremities have now gone through two winters with marked increase in vascularity. We have been unable to show, however, that an increased growth takes place in the paralyzed limb, possibly because the children were between ten and sixteen years of age. If the limb is hopelessly paralyzed, the normal stimulus of muscular contraction and weight bearing will be lacking and not much growth can be expected.

Reflex dystrophy, acute bone atrophy, stump neuroma, and causalgia are fundamentally identical with vasomotor and trophic disturbances which occur after mild soft tissue injuries, infections, venous thromboses, and fractures⁷. This syndrome is characterized by shiny, swollen fingers or toes, marked stiffness because of contraction of the joint capsules and

tendon sheaths, a spotty atrophy of bone, and marked sensitivity to heat and cold. Paroxysms of pain may be evoked by fright, unexpected noises or any emotional state. Conservative measures, such as heat, massage, diathermy fail in the severe cases. Psychotherapy is often needed because these patients are mostly of the neurotic type and have a low intelligence quotient. Almost specific relief may be obtained in the otherwise intractable cases, some of which have come to amputation, by sympathectomy. If a local source of irritation such as a perineuritis around the median or sciatic nerve, a periphlebitis or a stump neuroma cannot be found and removed, the reflex can be interrupted on the efferent arc by a sympathectomy. In five such intractable cases I have obtained excellent results.

Buerger's disease The diagnosis of Buerger's disease is not easy, even more difficult is it to predict its natural course. It is obvious that sympathectomy will not influence the progressive vascular inflammation, especially if it is widespread throughout the entire vascular system. Nevertheless, the fact remains that the lesion is predominantly in the blood vessels of the extremities. The acute stage characterized by a migrating phlebitis and arteritis is a definite contraindication to sympathectomy. These patients need rest, continuous heat, adequate fluids and salts. In a late stage where the reserve capacity of the vascular bed has been exhausted, when reflex heat or a block of sympathetic fibers shows little rise in the temperature of the digits, sympathectomy will be of no avail. There remains then a small group of cases—five per cent of my present material—in which there is no sign of any acute inflammation and in which tests can demonstrate the capacity of the vascular bed to dilate. In such patients sympathetic ganglionectomy has been of decided benefit. At present our indications for performing sympathectomy in Buerger's disease may be summarized as follows: (1) In patients with involvement of the fingers, with loss of phalanges, continuous pain, a cervicothoracic sympathectomy is advised. (2) On the lower extremity, if coronary or other visceral involvement is not demonstrable,

than ten hours, our results would have been vastly improved. The idea of utmost emergency in cases of acute arterial occlusion has somehow not reached or appealed to the medical profession. In this field we are still living in the pre-Murphy days of appendicitis. Peripheral arterial occlusion is still accepted as the inevitable forerunner of gangrene and amputation. Yet out of 296 embolectomies collected by Pearse, forty per cent operated on in the first ten hours were successful. The point that should be especially emphasized is that a vigorous treatment of the collateral vessel spasm, which is best accomplished by a combination of large heat cradles and intravenous injections or papaverine, may make an embolectomy unnecessary, but even these conservative measures fail unless promptly applied, preferably within ten hours following the arterial occlusion.

Sympathetic ganglionectomy. A sympathetic denervation of an extremity, done to improve impaired nutrition of the affected part, brings about the following changes in circulation: for the first five to eight days there is a flushing of the skin, increased pulsation of vessels, increased elimination of heat, and a rise in surface temperature. In a second stage, which usually begins in the second, occasionally in the third week, the skin becomes pale, the visible capillaries are contracted but show a rapid flow, and the pulsations return to the preoperative level. The fact that the vessels regain their *tonus* and that the fingers do not maintain the initial increase in pulsation³ has led some workers to believe that sympathectomy produces no lasting effect on circulation. This challenge has been made with such dogmatic assurance that it seems worthwhile to examine the evidence for increased circulation following sympathectomy. It is on this basis that the unquestionable clinical improvement in cases to be discussed later can be explained.

In the animal, the rate of blood flow per minute is approximately the double in the sympathectomized extremity. In man, measurements of blood flow have been made with indirect methods and show a permanently increased and fixed blood flow in the sympathectomized limb. Dr. Hick and I have found that satura-

tion of the venous oxygen rises after sympathectomy and remains elevated for at least several months after the operation.⁴ The increased oxygenation of tissues is what one tries to accomplish and not the increased pulse volume to which some seem to attach so much significance.

It is customary to remove the inferior cervical, first and second thoracic sympathetic ganglia to denervate the upper extremity. This can be done by an anterior low cervical or a posterior paravertebral approach. While technical details have no place here, I am more and more in favor of the anterior approach which is more difficult but allows for a more thorough identification of the structures to be removed. The convalescence of the patient is much more rapid. There are three possible approaches for the removal of the second, third, and fourth lumbar ganglia which is done for the sympathetic denervation of the lower extremity. Of these, with certain exceptions, the two-stage, anterolateral extraperitoneal approach is my choice, while the transperitoneal approach has been used less often in my clinic.

For both cervicothoracic and lumbar sympathectomies, local anesthesia with adequate premedication can be used successfully. In uncooperative or highly nervous individuals, the addition of a light gas anesthetic is advisable. The positive pressure apparatus is always in readiness in case the pleura should be punctured.

The types of vascular disturbances in which I have performed sympathectomies are as follows: Raynaud's disease, polyomyelitis with vessel spasm, reflex dystrophies, and Buerger's disease. The results require an individual analysis of these groups.

Assuming that the diagnosis of Raynaud's disease is correct, the results will differ according to the stage of the disease in which the operation is undertaken.⁵

In the first stage, there are no detectable structural changes in the arteries or in the soft tissues of the digits. The vessels dilate fully when relaxation is obtained by heating parts of the body. The late results are excellent in this group.

In a second stage in which there is ulceration of the finger tips or painful stellate scars at the end of slightly tapering digits,

and in which reflex dilation to heat produces only a slow and incomplete rise in temperature, the results are moderate but still worthwhile. The hand may become cold and arterial spasms may return but the progress of the disease is arrested and the attacks are less frequent. All patients in this group feel that they have benefited from the operation but the result is not as dramatic as in the first group.

In the third stage, patients have advanced structural disease of the arteries. The fingers will fail to heat up when heat is applied to the lower extremities. They suffer from a diffuse sclerosis of the digits involving skin, joints, tendons, a sclerodactyly secondary to an advanced Raynaud's disease. In such patients the late results are poor and a year or two after the operation the condition of the hands is no better than before. While in the first two groups the operation has been of great benefit, in the third stage it is useless.

In poliomyelitis with vessel spasm, the type of patient who will be benefited by lumbar sympathectomy has been described by Harris as follows⁶

In a child, preferably not older than eight years, if the paralysis is limited to one extremity and is moderate in degree, a sympathetic ganglionectomy will maintain an increased vascularity of the extremity and can result in accelerated growth of the shortened limb.

Scupham and I are studying three children who have been picked from Dr. Ryerson's material out of a group of twenty-five. Our experience has been favorable in that the cold, painful, plum-colored extremities have now gone through two winters with marked increase in vascularity. We have been unable to show, however, that an increased growth takes place in the paralyzed limb, possibly because the children were between ten and sixteen years of age. If the limb is hopelessly paralyzed, the normal stimulus of muscular contraction and weight bearing will be lacking and not much growth can be expected.

Reflex dystrophy, acute bone atrophy, stump neuroma, and causalgia are fundamentally identical with vasomotor and trophic disturbances which occur after mild soft tissue injuries, infections, venous thromboses, and fractures.⁷ This syndrome is characterized by shiny, swollen fingers or toes, marked stiffness because of contraction of the joint capsules and

tendon sheaths, a spotty atrophy of bone, and marked sensitivity to heat and cold. Paroxysms of pain may be evoked by fright, unexpected noises or any emotional state. Conservative measures, such as heat, massage, diathermy fail in the severe cases. Psychotherapy is often needed because these patients are mostly of the neurotic type and have a low intelligence quotient. Almost specific relief may be obtained in the otherwise intractable cases, some of which have come to amputation, by sympathectomy. If a local source of irritation such as a perineuritis around the median or sciatic nerve, a periphlebitis or a stump neuroma cannot be found and removed, the reflex can be interrupted on the efferent arc by a sympathectomy. In five such intractable cases I have obtained excellent results.

Buerger's disease The diagnosis of Buerger's disease is not easy, even more difficult is it to predict its natural course. It is obvious that sympathectomy will not influence the progressive vascular inflammation, especially if it is widespread throughout the entire vascular system. Nevertheless, the fact remains that the lesion is predominantly in the blood vessels of the extremities. The acute stage characterized by a migrating phlebitis and arteritis is a definite contraindication to sympathectomy. These patients need rest, continuous heat, adequate fluids and salts. In a late stage where the reserve capacity of the vascular bed has been exhausted, when reflex heat or a block of sympathetic fibers shows little rise in the temperature of the digits, sympathectomy will be of no avail. There remains then a small group of cases—five per cent of my present material—in which there is no sign of any acute inflammation and in which tests can demonstrate the capacity of the vascular bed to dilate. In such patients sympathetic ganglionectomy has been of decided benefit. At present our indications for performing sympathectomy in Buerger's disease may be summarized as follows: (1) In patients with involvement of the fingers, with loss of phalanges, continuous pain, a cervicothoracic sympathectomy is advised. (2) On the lower extremity, if coronary or other visceral involvement is not demonstrable,

if there is no spreading infection and marked arteriolar destruction, a bilateral lumbar sympathectomy is advocated. It is explained to both groups of patients that unless they maintain a complete abstinence from tobacco, unless foci of infection are eradicated, unless they continue with conservative measures, recurrences or further progress of the disease may be expected. The advantages of an operation in Buerger's disease are as follows. In the well-selected case, there is a striking improvement in the nutritional state of the extremities. Ulcers heal and the edema subsides, indicating that it is not necessarily due to venous obstruction. Should a sudden thrombosis of a larger vessel occur later, collateral vessel spasm will not be at play and the incidence of gangrene is diminished.

section is entirely postganglionic with a resulting degeneration of sympathetic fibers and sensitization to circulating vasoconstrictor hormones. In order to do an operation comparable to one on the lower extremity, one might leave the stellate ganglion intact, divide the white rami of the second and third thoracic nerves, and divide the sympathetic trunk below the third thoracic ganglion. At the suggestion of Telford⁹ I have performed this operation in two cases and the immediate results were excellent. It remains to be seen whether the late results will be better than with cervicothoracic ganglionectomy* (Table I).

Surgical Attempts to Alleviate Pain

In this group of cases, the structural disease of the arteries has passed beyond

TABLE I.—LATE RESULTS OF SYMPATHECTOMY IN PERIPHERAL VASCULAR DISEASE

Diagnosis	Stage of disease	Success	Improvement	Failure	Mortality
Raynaud's disease	First stage	3	0	0	0
	Second stage	6	2	0	0
	Third stage	0	0	2	0
Poliomyelitis	Unilateral, moderate paralysis	3	0	0	0
Reflex dystrophy	Severe, intractable	2	0	0	1
Buerger's disease	No acute process, no diffuse arteriolar involvement	6	3	0	1
Totals		20	5	2	1

An analysis of the causes of failure following sympathectomies for peripheral vascular disease reveals the following factors:

1. Improper stage of the disease (sclerodermic stage of Raynaud's, active inflammation or diffuse arteriolar involvement of Buerger's disease).

2. Technical failure in that incomplete number of ganglia are removed. This can be tested by the persistence of sweating in the denervated limbs.

3. Regeneration of sympathetic fibers which occurs when only ramisection is done and is again manifested by the return of sweating in previously dry areas.

There is one further possibility for the return of symptoms which is encountered on the upper extremity, and that is the sensitization of the denervated vessels to adrenalin and to thermic stimuli. This possibility was stressed by James White and his coworkers.⁸ Lumbar sympathectomy is a preganglionic section for the majority of the fibers going to the lower extremity with the exception of those fibers which join the femoral and obturator nerves. On the upper extremity, the

point where an appreciable reserve capacity exists. Furthermore the usual analgesics and sedatives have been of no avail or had to be steadily increased. The list of these operations is as follows:

Peripheral nerve block. The injection of alcohol, section and resuture or crushing of the peripheral nerves supplying the foot can be accomplished with short exposures five to six inches above the ankle. At this level no motor fibers are injured except those going to the small intrinsic muscles of the foot. Their paralysis is unnoticed by the patient. With three incisions, preferably done a few days apart, the entire foot can be desensitized. To ensure healing by first intention, incisions must be made only if the reactive hyperemia to histamine is adequate. This method has been of great service to patients suffering from the painful, ulcerated or gangrenous toes of Buerger's disease. Should minor amputations become necessary, they can be done without further anesthesia.

* A total of fourteen preganglionic thoracic sympathectomies have now been performed. The results are superior to those obtained by cervicothoracic sympathectomy and have persisted for over six months.

Healing of ulcers is facilitated by the sympathetic paralysis which may produce a marked rise in temperature. In arteriosclerotics and diabetics, I have been somewhat reluctant to do these nerve blocks unless collateral circulation is adequate at the level of the incisions. The anesthesia lasts three to four months, freedom from pain longer. In two patients the procedure was repeated at six month intervals. In one patient the circulation of the foot had improved to an extent that a lumbar sympathectomy could be carried out later.

This is a very efficient procedure and has no drawbacks if care is taken for very careful protection of the foot after desensitization.

Paravertebral nerve block This method imitates the effect of sympathetic ganglionectomy. However, in agreement with others it has been our experience that injection of the cervicothoracic chain is often followed by severe neuralgias and pleurisy. The lumbar sympathetic chain is at least two cm. in front of the lumbar nerves and is separated from them by the psoas muscle. Nevertheless, in two patients of a total of ten, a psoas weakness and painful paresthesias resulted from the injection of ninety-five per cent alcohol to the second, third, and fourth lumbar ganglia. The use of this method is limited to elderly arteriosclerotics with continuous rest-pain extending over the whole lower extremity. With accurate technic, the method is useful, relieves rest-pain but not intermittent claudication. For a temporary increase in circulation, paravertebral block may be made with novocain to relieve collateral vessel spasm in case of a sudden arterial obstruction or following the ligation of a large artery.

Methods to Remove Nonviable Parts

Amputation for intractable pain alone is hardly ever indicated since the advent of newer methods which I have just discussed. Amputation of a hopelessly paralyzed part is an occasional consideration. By far the most important indication for amputation is to remove a part which is hopelessly lost or which endangers the life of the patient because of absorption of toxins or spreading infection. In any large group of amputations, peripheral vascular disease still figures as the cause in about thirty per cent.¹⁰ The incidence of amputation in cases of Buerger's disease is definitely decreasing with earlier diagnosis and adequate treatment, but even Silbert's series shows that the fail-

ure to avert major amputation occurred in nine per cent of his cases. In a survey previously made, I had to amputate ten patients out of a hundred cases of Buerger's disease.¹¹ Minor amputations, loss of digits occur in a much larger percentage of cases. Arterial thrombosis and embolism require a certain number of amputations, but the greatest percentage of amputations is performed in patients with arteriosclerotic and diabetic gangrene. The latter have an additional tendency to gangrenous infection and septicemia.

It is outside the scope of this discussion to describe the technic of amputation. But the optimal time and the optimal level of amputation deserve some emphasis. The growing tendency for conservatism in the treatment of peripheral vascular disease is obvious. But this must not lead to unnecessary delay in facing inevitable amputations. So long as the gangrenous area is dry, there is no sign of ascending lymphangitis or phlebitis, no rise in temperature, and no chills, a trial with continuous heat, suction treatment, and waiting for spontaneous demarcation is permissible. But when the patient begins to look toxic—and it must be remembered that diabetic patients can have a positive blood culture without a rise in temperature—amputation should be urged and not be performed too late as a hopeless gesture. Under a low spinal anesthesia, my mortality of thirty-five amputations for gangrene was about twenty-two per cent but of course the mortality within one year is around fifty per cent, and in two years or more only one-third of the diabetic patients are alive and a third of these had bilateral amputations.¹²

Some confusion exists in regard to the proper level of amputation. In my experience, the cutaneous histamine reaction and the skin temperature are the two most helpful methods for the determination of the level of circulatory efficiency. One still sees surgeons picking off toenails or removing phalanges when amputation above the knee is necessary.

The surgeon should take further interest in the rehabilitation of the amputated patient. He should apply, if prompt healing has taken place, a temporary peg-leg within three weeks and not leave the rest of the work to limb manufacturers.

TABLE II—SUMMARY OF SURGICAL PROCEDURES FOR PERIPHERAL VASCULAR DISEASES

Operation	Number of operations	Success	Fail ure	Mortality
Embolectomy	5	2	3	0
Sympathectomy	28	25*	2	1
Peripheral nerve block	12	12	0	0
Paravertebral nerve block	10	8	2	0
Amputations	35	27	0	8
Totals	90	74	7	9

* Includes five improvements

Such a brief survey of the surgery of peripheral vascular disease cannot serve but to emphasize the fundamental objec-

tives of these methods. With early diagnosis and adequate conservative treatment, many patients will not be in need of such procedures. I offer deductions from such a small number of operations with humility and hesitation (Table II). They cannot justify sweeping conclusions. But a careful selection and close follow-up of a small number of cases may occasionally be of as much help as some undigested mammoth statistics.

Discussion

DR BEVERLY CHEW SMITH, New York City—Accurate clinical and pathological diagnosis of vascular diseases is at times as difficult as it is obvious. Practically I have found it most difficult to differentiate Monckeberg sclerosis from thromboangitis obliterans in patients over forty years of age. A carefully elicited history, complete physical examination, detailed examination of the extremities, including oscillogmetry, surface temperature readings and local reactions to various environmental and body temperatures, laboratory examinations including x-rays and a search for pathology elsewhere than in the extremities have afforded a basis for an accurate diagnosis. A history of phlebitis should be sought in all cases. I have encountered early vague peripheral vascular manifestations now attributed to abnormal sympathetic nervous system physiology which have not been able to be correctly diagnosed until multiple observations and examinations have revealed the trend of the true clinical course of the original complaints and even then some have defied an accepted nomenclature. Pathological diagnosis made from vessels of amputated digits has frequently been revised when higher amputations have afforded pathologists opportunity of studying larger arteries. Incorrect diagnosis predisposes to improper therapy and unwarranted prognoses.

Conservative treatment is indicated for a varying period of time except when infection of a part threatens patients with septicemia. In such cases conservative therapy

may prove fatal. If conservative treatment is tried and found effective, a continuation is justified as long as the local lesion and general condition of the patient show clinical improvement that is substantiated by laboratory data. In diabetics I require coincident approach to normal of the temperature, pulse, blood and urine chemistry, and blood count before I am satisfied that convalescence is positively established. Decision for amputation should be based upon the local and systemic pathology, the clinical condition and its course, the financial and social status of the patient, and the prognosis as regards the usefulness of the part affected as well as the patient as a whole. The time for correct surgical intervention in this group of cases is often difficult and is best apprehended by those conversant consistently with the hospital care of peripheral vascular disease.

Regarding efforts to alleviate pain, the choice of proper treatment depends upon the status and prognosis of the individual case. The clinical leeway for regression or progression of local pathology in peripheral vascular disease is often so slight that clinical astuteness gained from previous observations and combined with experience of prognosis is required to neither over or under treat these patients. All treatments should be of a mild degree. Multiple mild treatments are more efficacious than single severe ones. Machine treatments are dangerous. Patients in any machine should be carefully and persistently observed. It is dangerous therapy to adapt a patient with

pathology to a set machine. The machine should either be adaptable to the individual patient or else it should not be used.

In the absence of infection, palliative treatments such as rest, sedative, whirlpool baths, massage, elevation and depression exercises, environmental temperature not over 93°F, alcohol in small doses, pedecures, protection of pressure points, general nursing care, and a condition of mental rest will often be effective.

In the presence of infection in toes particularly in thromboangitis obliterans, arteriosclerosis with and without diabetes mellitus, if palliative treatments as mentioned, along with appropriate surgical dressings do not relieve pain, I do not hesitate to employ peripheral nerve block of the deep and superficial peroneal, posterior tibial, sural, and internal saphenous nerves by exposure under local or general anesthesia and crushing of the nerves for varying distances with a small hemostat depending upon the time I desire the anesthesia to last. Relief of pain, accompanied by anesthesia of the part, permits more intensive local surgical treatment, release from sedatives, a marked improvement in the patient's appetite and weight, and more normal and physiology of their vascular, nervous, digestive, and genitourinary systems.

I have blocked 141 peripheral nerves in the lower extremities of forty-six cases of obliterative arterial disease in the past five years, by either alcohol injection, alcohol injection and crushing, division and suture, or crushing. Pain was completely relieved in ninety-seven per cent of the thromboangitis obliterans group and ninety per cent of the arteriosclerotic group, eighty-one per cent of the arteriosclerotic with diabetes group were relieved of seventy-five to one hundred per cent of their pain. Some degree of pain persists in the anesthetic areas of a few of the nerve block cases. The explanation of this result in a few cases has been difficult. Most instances are probably due to abnormal branching and distribution of branches of the nerve above the block site. I now prefer to block nerves by crushing with a small hemostat. A single crushing over three-four mm will give anesthesia of the part supplied by the nerve for about six months, a second adjacent crush will add three to four months more of anesthesia, and a third, three to four months more, or a total of twelve to fourteen months. Return of sensation is heralded by a paresthesia which may be slightly uncomfortable.

Nerve block is a simple anatomical operation of great clinical value for relief of pain

in these patients. It should not be attempted until the operator is familiar with the nerve anatomy, as unnecessary extensive dissection in tissues of diminished blood supply may precipitate further local ulceration or gangrene. The greatest technical difficulty is encountered when nerves are not in their usual anatomical situation or present abnormal branches with unusual distribution.

Regarding methods to remove nonviable parts, I published (*Archives of Surgery*, August 1933) a technic of an amputation through the leg in cases of gangrene of an extremity from thromboangitis obliterans, diabetes mellitus with and without diabetes, and in over fifty cases so treated I have only reamputated one case because of extension of gangrene in the stump. If an amputation is properly done in these cases, it should not be necessary to perform it through the thigh unless the local acute pathology has ascended into the middle third of the leg. The pulsation of the popliteal artery is not always a true criterion for the type of healing one may obtain in an amputation stump of the leg. I think the day has come to evaluate amputation results. I am convinced that routine thigh amputations because of foot or toe pathology are too radical, unnecessary, and unwarranted, and should be stopped. Besides extensive acute pathology, the only other indication for a thigh amputation in these cases is chronic pathology in or about the knee joint which would prevent the use of a prosthesis suited to a stump below the knee.

As regards embolectomy, I have had no experience with papaverine hydrochloride. I shall try it the next time I see such a case. Results in both early and late cases at Presbyterian hospital have been bad. The mortality is high and the number of postembolectomy thromboses with subsequent gangrene is also high. The associated cardiac condition in our cases has been particularly bad and multiple successive embolic phenomena have been the rule. In early selected cases in the extremity, I shall continue attempted operative removal after evaluation of the patients local and general condition and if possible, use a unilateral spinal anesthesia.

I have used the pressure suction machine in four cases of embolus of the lower extremity vessels. Two could not tolerate the machine because of increased pain. Three continued to gangrene necessitating amputation and the fourth was subsequently amputated because of fibrosis and contracture of the calf muscles leaving him with a cold blue painful useless extremity in spite of the fact that it was completely healed.

In the cases of Raynaud's disease, my re-

TABLE II—SUMMARY OF SURGICAL PROCEDURES FOR PERIPHERAL VASCULAR DISEASES

All treatments should be of a mild degree. Multiple mild treatments are more efficacious than single severe ones. Machine treatments are dangerous. Patients in any machine should be carefully and persistently observed. It is dangerous therapy to adapt a patient with

2 Cases of hay fever, which become free clinical manifestations as a result of desensitization treatment, have as high even a higher titer of P-K antibodies in their serum as was present before hypodermization and while the patients were suffering from clinical manifestations. Many cases of infantile eczema have a high titer P-K antibodies to egg-white, but, in some of these cases, egg-white desensitization produces no clinical manifestations. The same holds true with other antigens and inhalants in atopic dermatitis of

which exposures regularly produce clinical manifestations, without, however, producing clinical manifestations of clinical hypersensitivity except in the rarest instances. Desensitization, for example, produces clinical manifestations in the majority of infants, despite the presence of these antibodies in the host is, as a rule, free of clinical manifestations.

Observations surely demonstrate that the presence of antibodies has not been sufficient to prevent all doubt. Nevertheless, most observers that hay fever is due, in all probability, to an antibody reaction. Multiple, has shown that when antigens are injected into the nostrils or membranes of the nose and when this procedure is followed by exposure to allergen, the clinical manifestations of hay fever are not observed. This is a mass of further clinical evidence which shows that P-K antibodies are responsible for the clinical manifestations of hay fever and in some cases, provided always that there is no known concomitant hypersensitivity (presence of

specific sensitization), and in almost all cases except perhaps in the case of serum sickness, where the hypersensitivity is responsible and antibodies are the most tenuous of factors. The possibility of the development of cell-fixed antibodies can have no

classical observation of the occurrence of antibodies in the blood from an

bearing upon the present question of classification or upon the present exact definition of the term "allergy."

It seems to me, therefore, that the demand for the antigen-antibody reaction in the definition of allergy is today untenable, as it would still have to exclude almost every accepted specifically altered state in human beings and many such states in animals.

Some authors avoid this obviously insurmountable difficulty by hypothesizing the presence of antibodies (cell-fixed tissue antibodies) in those specifically altered states in which no antibodies have, as yet, been demonstrated. I, too, believe in the possible presence of such antibodies, but I hold that the hypothesis as to their presence cannot be made the criterion (or limit) of a scientific definition. It must be clear and unanswerable that, if the hypothesizing of the responsibility of antibodies is admissible in any one state of specifically altered reactivity, such an hypothesizing must be equally admissible in any other such state. In other words, the postulation of hypothetical antibodies cannot, in any way, contribute to the clarification or definition of the concept of allergy. As long as one admits that the antibodies need be only hypothetical, allergy reverts to the original definition embracing all specifically altered states.

Another suggestion for modification of the original definition of allergy consists of *confining the term to specifically acquired hypersensitivity*. This would exclude the phenomena of specifically acquired *hyposensitivity* and specifically acquired *immunity*. These exclusions are so obviously contrary to the fundamental principles involved that only a few words are necessary to illustrate the impossibility of confining the concept "allergy" to the phenomenon of specifically acquired *hypersensitivity*.

The very reason for the formulation of the concept "allergy" was the close connection and interdependence of the phenomena of acquired hypersensitivity and hyposensitivity. The same preparatory exposures may lead to one or the other, and often to the concomitant appearance of both. In fact, it is the rule to find certain phenomena of hypersensitivity coupled and associated with

If conservative treatment is tried and found effective, a continuation is justified as long as the local lesion and general condition of the patient show clinical improvement that is substantiated by laboratory data. In diabetics I require coincident approach to normal of the temperature, pulse, blood and urine chemistry, and blood count before I am satisfied that convalescence is positively established. Decision for amputation should be based upon the local and systemic pathology, the clinical condition and its course, the financial and social status of the patient, and the prognosis as regards the usefulness of the part affected as well as the patient as a whole. The time for correct surgical intervention in this group of cases is often difficult and is best apprehended by those conversant consistently with the hospital care of peripheral vascular disease.

Regarding efforts to alleviate pain, the choice of proper treatment depends upon the status and prognosis of the individual case. The clinical leeway for regression or progression of local pathology in peripheral vascular disease is often so slight that clinical astuteness gained from previous observations and combined with experience of prognosis is required to neither over or under treat these patients. All treatments should be of a mild degree. Multiple mild treatments are more efficacious than single severe ones. Machine treatments are dangerous. Patients in any machine should be carefully and persistently observed. It is dangerous therapy to adapt a patient with

ALLERGIC MANIFESTATIONS IN DERMATOLOGY

MARION B SULZBERGER, M D, *New York City*

You have just heard an excellent and detailed discussion of the role of allergy in certain skin eruptions due to fungi, foods, drugs, and occupational hazards*.

I do not feel called upon, nor would it be possible for me, here to add any important specific and pertinent details to the already comprehensive remarks of the previous speakers. I feel rather that the subject assigned to me clearly shows that I am intended to pass from the specific to the general, and that I should attempt to present the reasons for unifying so many dissimilar and apparently unrelated dermatoses under the one concept of allergy.

You have indeed heard comprehensive discussions of the role of allergy in four different types of skin diseases.

But these four, although important representatives, are only selected examples chosen from among the many dermatologic manifestations in which allergic alterations are of proven fundamental and outstanding significance. For the mere mention of only a few more such conditions dominated by allergy—syphilis, tuberculosis, leprosy, vaccinia, malleus, serum sickness, and atopic dermatitis (neurodermatitis)—the mere visualization of these different clinical pictures will suffice to show how diverse and apparently unrelated the manifestations of allergy may be.

It is therefore the object of this contribution to show that allergy plays a significant part in diverse dermatologic manifestations. Since the previous speakers have so adequately discussed the details of the specific basic experiments and observations, it becomes my task to demonstrate that these phenomena fall within the confines of allergy in general, according to its present interpretation and meaning.

There has undoubtedly been consid-

* This was the fifth and final paper in a Symposium on "Allergy in Dermatology."

erable discussion, not to say controversy, about the meaning and the limits of the word "allergy," and a great deal of confusion has thus ensued. I believe that this is largely because of the great diversity in the manifestations of allergy, and because of the continually increasing number of manifestations to which the concept of allergy can, in my opinion, rightfully be applied.

I am not unaware that many criticize the application of the term allergy to such a multitude of various phenomena. These critics seem to believe that a concept applied so widely must thereby lose in precision, and thus in value.

It does not necessarily follow, however, that a wide concept need be vague. For, even though a concept be wide, the necessary degree of precision can be maintained as long as a sharp definition be accepted and preserved. As v Pirquet (1906) foresaw when he coined the word "allergy," the very wideness of this concept has proven to be perhaps its most valuable property. For the application of the broad concept of allergy has enabled investigators of many different diseases to study their diverse manifestations from a common, instructive, and thus eminently profitable viewpoint.

Many observers warn against the dangers inherent in the rapid increase in the number of manifestations now being attributed to allergy. These dangers are surely real and apparent, and, in my opinion, they can be obviated only by the general acceptance of a precise definition of the term "allergy." I therefore feel that it is not amiss once again to quote the original definition of v Pirquet,¹ as well as some of his explanatory remarks. v Pirquet says, as follows:

We are in need of a new, general, non-prejudicial word to designate the altered condition which an organism achieves after acquaintance (Bekanntschaft) with any organic, living, or inanimate poison.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

sults have been both good and bad. Resection of the first and second dorsal sympathetic ganglia give temporary results. Additional resection of the inferior cervical ganglion added the deformity of a Horner's syndrome but gave more permanent relief of vasomotor spasm, permitted ulcers on distal closed spaces to heal, and relieved pain. The results at two years in the group has only been about fifty per cent. Vaso-spastic phenomenon have returned in minor to major degrees. In those cases with advanced sclerodactylic changes the return to their preoperative status has been most marked. They are hypersensitive to adrenalin as noted by White and Smithwick of Boston as attested by their surface temperature drop when given 1000 c.c. of adrenalin (1:250,000) intravenously. Further attempted relief in this adrenalin sensitive group is in abeyance for the time being. I plan to precede with subsequent Raynaud's cases as advocated by Smithwick—namely division of the dorsal chain below the third ganglion—implantation of the proximal end into the erector spinal muscle group to prevent regeneration and evulsion of the pre-ganglionic fibers by removing the second and third intercostal nerves medial to the sympathetic chain up to the spinal foramina. The follow-up results in the cases so treated have not been of sufficient duration to be

stated at this time. The immediate post-operative clinical results are good.

Lumbar ganglionectomy has been more permanently efficacious than the dorsal operation. The use of this procedure in other than true Raynaud's for vascular disease should be instituted with considerable judgment and thought. It remains a procedure of surgical magnitude. Preoperative novocain block tests are indicated before all sympathetic ganglion operations. Particular care in the dorsal region should be taken not to enter the pleura, lung or spinal canal with the injection fluid. I prefer to study finger temperature changes by blocking with an infiltration novocain procedure the median nerve at the wrist and the ulnar at the posterior elbow region, and for the toes the posterior tibial nerve below the internal malleolus as advocated by Scott and Morton. Both of these procedures are harmless when carried out aseptically.

Recent advances in the treatment of vascular extremity diseases have assumed such proportion as to justify the institution of a special clinic for such case treatments in hospitals. In the past five years in a limited Peripheral Vascular clinic at Vanderbilt clinic we have not had to do a single amputation for gangrene in some 400 cases cared for which came to us without gangrene. To my mind this fact justifies the efforts expended in this clinic.

THE BETTER KIND OF CHICAGO GRAFTERS

Engaging possibilities loom as we read in a scientific journal of the successful transplantation of the leg of one animal to another animal of the same species. The Sunday supplement writers are no doubt already busy with pen and pencil foretelling what wonders this will mean for mankind, so no effort will be made here to rival their flights of genius.

Writing in *Science*, journal of the American Association for the Advancement of Science, J. V. Schwind of the Loyola University School of Medicine, Chicago, describes an operation in which he succeeded in grafting a leg of an albino rat upon the body of another rat in such a way that the transplanted limb retained its muscular activity. He used methods similar to those of plastic surgery whereby skin is taken from one part of the body and placed upon another part.

Referring to Dr. Alexis Carrel's experiment in 1907, when a leg was transplanted on a dog, Mr. Schwind said that in that case, although the new leg healed normally,

"no regeneration of nerves or return of functions of the muscles were reported."

"In the experiments reported here," he went on, "successful transplantation of entire legs was accomplished and, in addition, re-establishment of considerable muscular control of the new leg was obtained."

He explained that in making the experiment the two animals were joined together at first, so that the transplanted leg continued to receive enough circulation from the body of the first animal to maintain its life as transplanted. When tests showed that the transplanted leg had made its new circulatory connections with the body of the second animal, the leg was completely amputated from its original owner.

"After several weeks," he went on, "slight motion was apparent in the new leg, which was massaged and exercised daily. There was a gradual increase in the muscular response until the leg was able to lift a ten-gram weight over one centimeter."

2 Cases of hay fever, which become free of clinical manifestations as a result of hyposensitization treatment, have as high or even a higher titer of P-K antibodies in their serum as was present before hyposensitization and while the patients were still suffering from clinical manifestations

3 Many cases of infantile eczema have high titer P-K. antibodies to egg-white, and yet, in some of these cases, egg-white ingestion produces no clinical manifestations. The same holds true with other foods and inhalants in atopic dermatitis of adults

4 Certain exposures regularly produce P-K. antibodies, without, however, producing manifestations of clinical hypersensitivity, except in the rarest instances. *Ascaris* infestation, for example, produces P-K. antibodies in the majority of instances. But, despite the presence of these antibodies, the host is, as a rule, free of clinical manifestations

These observations surely demonstrate that the role of antibodies has not been proven beyond all doubt. Nevertheless, I agree with most observers that hay fever and asthma are due, in all probability, to an antigen-antibody reaction. M. Walzer, for example, has shown that when P-K. antibodies are injected into the normal mucous membranes of the nose and conjunctivae, and when this procedure is followed by exposure to allergen, the clinical manifestations of hay fever are reproduced. There is a mass of further experimental and clinical evidence which supports the opinion that P-K antibodies are actually responsible for the clinical sensitivity in hay fever and in many cases of asthma,* provided always that certain as yet unknown concomitant factors are present as well (presence of shock-tissue, etc.)

But in all the other specific sensitizations I have mentioned, and in almost all human sensitizations except perhaps asthma, hay-fever and serum sickness, the role of responsible antibodies is the sheerest and most tenuous hypothesis. They have not been demonstrated to date, and the possibility of the ultimate demonstration of cell-fixed antibodies in these conditions can have no

* For example, the original classic observation of M. Ramirez demonstrating the occurrence of asthma in a previously normal individual after receiving a transfusion of blood from an asthma patient.

bearing upon the present question of classification or upon the present exact definition of the term "allergy"

It seems to me, therefore, that the demand for the antigen-antibody reaction in the definition of allergy is today untenable, as it would still have to exclude almost every accepted specifically altered state in human beings and many such states in animals

Some authors avoid this obviously insurmountable difficulty by hypothecating the presence of antibodies (cell-fixed tissue antibodies) in those specifically altered states in which no antibodies have, as yet, been demonstrated. I, too, believe in the possible presence of such antibodies, but I hold that the hypothesis as to their presence cannot be made the criterion (or limit) of a scientific definition. It must be clear and unanswerable that, if the hypothecation of the responsibility of antibodies is admissible in any one state of specifically altered reactivity, such an hypothecation must be equally admissible in any other such state. In other words, the postulation of hypothetical antibodies cannot, in any way, contribute to the clarification or definition of the concept of allergy. As long as one admits that the antibodies need be only hypothetical, allergy reverts to the original definition embracing all specifically altered states.

Another suggestion for modification of the original definition of allergy consists of *confining the term to specifically acquired hypersensitivity*. This would exclude the phenomena of specifically acquired *hyposensitivity* and specifically acquired *immunity*. These exclusions are so obviously contrary to the fundamental principles involved that only a few words are necessary to illustrate the impossibility of confining the concept "allergy" to the phenomenon of specifically acquired *hypersensitivity*.

The very reason for the formulation of the concept "allergy" was the close connection and interdependence of the phenomena of acquired hypersensitivity and hyposensitivity. The same preparatory exposures may lead to one or the other, and often to the concomitant appearance of both. In fact, it is the rule to find certain phenomena of hypersensitivity coupled and associated with

The vaccinated individual reacts differently to the lymph, the luetic to the syphilis virus, the tuberculous [person] to tuberculin, and the one injected with serum reacts differently to the serum, than does an individual who has never yet come into contact with the given agent. He is, nevertheless, as yet far from being immune because of this. All we can say about him is that his capacity to react has been altered (Reaktionsfähigkeit geändert ist)

I suggest the word "allergy" to designate this general concept of *altered reactivity*. "Allos" designates an aberrance from the original state (Verfassung), from the behavior of the normal, as in allorhythmia, allotropism.

The vaccinated [person], the tuberculous [individual], he who has been injected with serum—all become *allergic* to the respective foreign substance. Furthermore, a foreign substance which, after one or more contacts, influences an organism to alteration of reaction, is an *allergen*. The expression is derived—indeed in a non-philological manner—from the designation "antigen" (Detre-Deutsch), which means a substance capable of producing antibodies. The concept "allergen" goes farther: the allergens include, in addition to the antigens, numerous protein substances which do not produce antibodies, but do cause hypersensitivity. All agents of those infectious diseases which are followed by immunity are allergens. Also to be considered as allergens are the poisons of mosquitoes and of bees, insofar as manifestations of hypo- and hypersensitivity follow contact with these agents. For this same reason, we must also include as *allergens* the pollen of hay fever (Wolff-Eisner), those substances in strawberries and in crabs which bring about urticarial reactions, and probably also a whole series of organic substances which produce idiosyncratic reactions.

I know that there are many who say that the pronouncements of v Pirquet need no longer be accepted as gospel, in spite of the fact that he was the originator of the word "allergy." I freely admit that it is not necessary in medicine to adhere blindly to definitions once they have become outworn and outgrown. However, when such an old, accepted definition is to be altered or amended, it is imperative that the suggested modifications be clearly defined. And it seems to me not only that v Pirquet's definition is still the one which is most tenable and precise, but that none of the critics have

advanced a new or a clearer definition which satisfactorily describes and adequately embraces the recognized phenomena of human and animal allergy.

For these reasons, the attempts to alter v Pirquet's adequate, precise, and established definition have been futile, and have brought about unnecessary confusion.

I should like to discuss a few of the most commonly suggested modifications of v Pirquet's definition, and thus of the concept of allergy.

There are some, for example, who would *postulate the demonstration of responsible antibodies* to justify the application of the term "allergy." Quite aside from the fact that this is in direct contradiction to the original and long-accepted definition, this postulation of an antigen-antibody reaction at present automatically excludes from allergy almost all the well-known specific sensitizations in human beings. For, with present methods, no antibodies can be demonstrated to be the causes of the specifically altered states in such conditions as tuberculosis, syphilis, mycotic affections, smallpox, drug sensitizations, contact eczema, many food idiosyncrasies, and in a greater number of other pathologic states which are recognized as being the very prototypes of allergic reaction. In other words, the demand for the proven responsibility of antibodies would exclude from allergy the phenomena of tuberculin, luetin, and trichophytn allergy, the allergy of revaccination, drug sensitizations and desensitizations, and the sensitizations of eczematous type including even those which have often been deliberately produced with plant products and simple chemicals.

Even in hay fever and in asthma, there is no proof absolute that the specific Prausnitz-Kustner antibodies so frequently encountered are the actual causes of the clinical sensitivity. For, if antibodies are responsible in these conditions, it is still difficult to explain the following observations:

1 There are many typical cases of asthma in which no antibodies can be demonstrated, in fact, in asthma due to hypersensitivity to drugs (aspirin, etc.), no antibodies have been found.

thus phenomenon, etc. It must be clear, therefore, that while all these are undeniably distinct and different forms of hypersensitivity, they all have in common a basis of a specifically altered capacity to react, due to previous exposure, and made manifest by subsequent exposure to the same or to a closely related substance.

I hope that my remarks may have in some measure served to explain why such divergent manifestations as those found in hypersensitivity to foods, in drug eruptions, in fungus diseases of the skin, and in occupational dermatoses have all been included under the common heading of allergic skin diseases.

In order to include them under this heading, it is necessary to show only that their manifestations, however divergent, are dependent, to a greater or lesser degree, upon a specifically acquired altered capacity to react. I do not doubt that the detailed expositions of the previous speakers have made clear the various proofs (1) of the existence of specifically altered states in the skin diseases discussed and (2) of the profound influence the specifically altered capacity to react exerts upon the course and manifestations of these skin diseases.

It is surely unnecessary for me to recapitulate these proofs or to submit any further evidence in the way of concrete citations from the literature. I may state, however, that, in a like manner and step by step, through years of painstaking research, allergy has been shown to be an essential factor in the course of many skin conditions not mentioned in this symposium. The clear demonstration of the role of allergy in tuberculoderms and syphiloderms, in leprosy and lymphopathia venerea, in serum sickness and in atopic dermatitis (neurodermatitis disseminata), and in other skin conditions too numerous to mention—in all these diseases, allergy has been demonstrated and its role proven by experiments and observations essentially and fundamentally the same as in the particular dermatoses which have been the chosen subjects of this symposium.

The nature of my remarks makes it imperative for me to warn emphatically

against certain possible misinterpretations. The possibility exists that some may conclude that, because all these varying manifestations are to be considered allergic, they must also at the same time be considered identical with, or closely similar to one another. This is, of course, far from being the case. In fact, I feel that it is of the utmost necessity to realize that, for the present at least, these different manifestations of allergy are not to be identified with one another, except as regards their belonging under the one broadest classification of phenomena due to a specifically acquired capacity to react. The altered capacity to react, as found in asthma, hay fever, and urticarial skin responses, surely appears to be entirely different from the altered state in eczematous contact dermatitis. For example, the altered capacity to react in tuberculum hypersensitivity and in tuberculoderms is apparently entirely different from that in fixed drug eruptions, and it is equally obvious that all these allergic states are not only seemingly different from one another, but also from the allergy as seen in the specifically acquired hypersensitivity of the anaphylactic animal.

As long as one does not lose sight of these undeniable differences characterizing the various forms of allergy, it is constructive to bear in mind the common basis of all these phenomena. For this understanding of a common basis enables one, through application of certain common concepts, to arrive at a wider comprehension of these phenomena, and, through application of certain common methods and technique, to progress in their study and in their management.

Those who criticize the concept of allergy for being too broad, probably feel that the application of such a broad term fails to clarify the nature of a phenomenon to any valuable extent. Their stand would be well-taken if it were true that the designation of a manifestation as "allergic" were intended to constitute a complete or final pronouncement as to its nature, morphology, etiology, or pathogenesis. But this is no more true than when one designates a certain manifestation as being "infectious," for example. No one today objects to a general classi-

phenomena of hyposensitivity in the same individual or in the same experimental animal. I need only recall the fact (1) that injections of foreign substances in animals can lead to both anaphylaxis and antianaphylaxis, (2) that, in the course of tuberculin hypersensitization, there is often a period of tuberculin hypersensitivity, (3) that, in infectious diseases such as tuberculosis, syphilis, and fungus affections, there is a constant interplay of manifestations of hypersensitivity and of increased resistance, or hyposensitivity (positive or specific anergy).

At the present state of our knowledge of the processes leading to specifically acquired hypersensitivity, hyposensitivity, and immunity, it is impossible to regard these as essentially unrelated phenomena. On the contrary, they are clearly subject to the same or analogous immunologic laws, and it continues to be necessary to regard them from a common viewpoint as manifestations of allergy. (This statement by no means implies that hypersensitivity and immunity are identical, nor that the one cannot exist without the other.)

Another attempted modification of the concept of allergy is undertaken by those who would *exclude from allergy those specifically altered states which are produced by living organisms*. In other words, these authors would have to consider all specifically acquired altered states in *infectious diseases* as not belonging within the confines of allergy. All that need be said here is that even the most cursory consideration must make it apparent that such an exclusion is utterly impossible. The very pillars of the concept rest upon specific alterations in infectious processes such as vaccinia, tuberculosis, syphilis, diphtheria, and fungus diseases. Furthermore, an inclusion of reactions produced by nonliving agents and exclusion of reactions produced by living agents would lead to the following absurdities, among others:

1 The phenomena of specific, acquired hypersensitivity to fungi would *not* be termed *allergic* when made manifest by reinoculation with the *living* organisms, but would have to be termed *allergic*, when

brought to light by the injection of the nonliving trichophyton.

2 Koch's fundamental experiment would *not* be accepted as an allergic phenomenon (reinfection with *living* bacilli), while tuberculin reactions would be accepted as allergic in nature.

3 The hay fever attack produced by exposure to the *living* pollen would *not* be termed an allergic reaction, but the response to skin test with the nonliving pollen-extract would necessarily be considered an allergic reaction.

4 Sensitization produced by contact with a *living* plant, such as ivy or primrose, would *not* be accepted as an allergic sensitization, whereas sensitization with Bloch's crystalline primrose excitant, or with ivy extract, would have to be included among the phenomena of allergy.

5 *Rhus dermatitis* would *not* be allergic, lacquer (*Rhus*) dermatitis on the other hand would be included in allergy.

These few examples will surely suffice to show how necessary it is to retain Pirquet's concept that an allergen may be either a "living" or a "nonliving" agent.

Still another attempt to limit the application of the term allergy has been advanced by those who would see the definition of allergy *confined to the acute, explosive clinical manifestations* of the type of asthma, hay fever, and urticaria, and characterized histologically by certain types of tissue response accompanied by edema and eosinophilia. Fortunately, there are but few authors who still have the temerity to advance this unsound and hopelessly untenable limitation.

I am confident that all the aforesaid must have made it sufficiently clear that the largest number of the manifestations of specifically acquired hypersensitivity do not fall within the category of the acute, explosive reactions. Reactions of the asthma, hay fever, and urticaria types are merely representative examples of a certain form of specifically altered reaction. Specific sensitization processes—as has been shown repeatedly—lead not only to such explosive types of hypersensitivity, but to a multitude of other reaction forms, as exemplified by the tuberculin-type reaction, eczematous reaction of contact dermatitis, sarcoid reactions in many infectious diseases, Ar-

clinical division or identification. For example, I see no reason for referring to one type of dermatitis as atopic. This is confusing and misleading as it implies a different fundamental concept. I should rather refer to all classes of dermatitis due to specific hypersensitiveness as allergic dermatitis, and when the specific etiology has been established in a particular case it may then be recorded as allergic dermatitis—contact type, etc. A subdivision of allergy based on a history of heredity is on the face of it untenable. The percentages of positive histories of antecedent allergy in a given case depends entirely on what conditions are included in the questionnaire as being allergic. Years ago statistics were drawn up concluding that forty per cent of hay fever and asthma patients gave a positive history of allergy in their antecedents. These figures were established by asking the patients whether or not any of their antecedents had had asthma or hay fever. It is obvious that the figures would be radically changed when we include urticaria and eczema in our questionnaire, and again when we include various forms of dermatitis, migraine, gastrointestinal disturbances, etc. It is impossible to establish accurate figures relating to the hereditary influence in a condition which is still so vague and where additional pathological changes are constantly being added to our list of accepted allergic diseases, as our knowledge and understanding of allergy increases.

I agree with Dr Sulzberger that the presence or absence of reagins in the circulating blood cannot be accepted as a basis for classification. Dr Sulzberger has advanced so many convincing arguments that it is unnecessary for me to take up time in what would be merely repetition. Peshkin in a recent contribution on the perennial treatment of pollen allergy showed that many cases who gave positive skin reactions to pollen prior to starting treatment, became skin negative to pollen tests and also showed an absence of demonstrable reagins in the circulating blood though many of them still had clinical symptoms of pollen allergy.

As an internist keenly interested in clinical allergy since 1914, I want to sound a note of caution. I have seen waves of overenthusiasm sweep the country and I

have seen evidence of unfair and undue skepticism regarding the clinical practicability of allergy. Both the overenthusiasm and skepticism are the result of lack of fundamental understanding of the phenomenon under discussion. Unfortunately, we must admit that it is only too common an occurrence to have men in general or special practice doing skin tests or having an office nurse do skin tests on their patients with no more background or instruction than a demonstration by some salesman representing a commercial house that will supply the doctor with allergens and treatment sets with complete schedules of dosage, etc. I am not talking about occasional cases for until recently, this was the rule rather than the exception and it was the exception that devoted sufficient time, effort, and thought to a study of the fundamental underlying principles of allergy before attempting to diagnose and treat allergic manifestations. To many, allergy means skin tests, which to them merely means the making of a few scratches and applying the allergen. They completely overlook the great importance of experience and training in the proper interpretation of skin reactions and, what is even more important, the evaluation of skin reactions. This cannot be treated lightly if one wishes to benefit from this additional aid to accurate diagnosis. Certainly no dermatologist would tolerate a skepticism or criticism of the value to dermatology of skin biopsy studies were this skepticism voiced by practitioners without proper knowledge and training in skin pathology.

One must guard against undue and unsound overenthusiasm and not be carried too far by theory, however, the fact that innumerable clinical disorders are the result of a specific hypersensitiveness is now well-established and recognized. It is earnestly recommended that a more serious attempt be made to instruct physicians and students in the fundamental underlying principles of allergy and that recognizing the impossibility of becoming expert in every branch of medical practice, that a more effective cooperation be established between those not particularly interested and those intensely interested in allergy and equipped to properly investigate a case from this standpoint.

WHY THE BIG TRIAL HANGS FIRE

The great court trial to decide whether the Coney Island blood-pressure-testers were illegally practicing medicine has been postponed indefinitely, as the one who was

arrested has jumped his bail and gone to parts unknown. If he is not recaptured, the matter may be shrouded in doubt forever.

fication of certain manifestations as "infectious," in spite of the fact that many of these manifestations are widely divergent in every respect, except for the one common attribute that they are all due to living agents. The classification of these many conditions as "infectious" has surely proven to be constructive, as it has enabled us to study them under certain common laws.

Just so has it been proven of great value to designate many divergent skin manifestations as "allergic."

However, the concept of allergy will continue to be valuable in the study of skin diseases, only if dermatologists remember that the designation "allergic," far from being a final disposition, merely signifies that a given manifestation can now be envisaged from the common viewpoint applicable to all phenomena based upon a specifically acquired altered capacity to react.

von Pirquet's concept has proven to be of incalculable value, both theoretical and practical, in dermatology, and it promises to continue to be so, as long as we bear in mind that calling a condition "allergic" is only the first step leading to its investigation and study with the methods and technic, and under the common laws of allergy.

It is certain that my colleagues in this Symposium, Drs. Abramowitz, Hopkins, Peck, and Schwartz, have done ample justice in citing the many investigators who have contributed in such outstanding fashion to the establishment and

development of the study of allergy and its manifestations. I have therefore refrained from mentioning specific names or references. However I should like to recall that it was certainly Bela Schick, who was a foremost pioneer (1903-1905 and 1906) and who has contributed among the most important and original observations in this field (Serum disease, tuberculin allergy, the theory of the incubation period, etc.) His published works were among the very first to clearly demonstrate the quantitative and qualitative alterations in allergy.

I must refer to the excellent bibliography of von Pirquet's article² for the further information of those who wish to penetrate more deeply into the early development of studies in these immunologic phenomena. Among the 142 references to authors of basic early works will be found such important contributors as Karl Landsteiner, Finger, Moro, Rosenau and Anderson, Otto, Richet, Koch, Detre-Deutsch, Wolff-Eisner (the first to recognize the nature of the hypersensitivity in hay fever), Wassermann, Arthus, Besredka, Calmette, Blackley, Dunbar, and many other equally important names.

Among the many authors of subsequent dermatologic contributions to allergy, two names are of such undoubted pre-eminence that I am certain you have heard them repeatedly. I refer to the two most illustrious pioneers in dermatologic immunology, J. Jadassohn and Bruno Bloch.

Now that these two have finally ceased their works, it is but fitting that we recall how much of our present knowledge of dermatologic allergy is directly or indirectly due to the wide vision, the patient experimentation, and to the inspiring influence of these two masters.

Discussion

DR. MAXIMILIAN A. RAMIREZ, *New York City*—At the outset I wish to congratulate Dr. Sulzberger on his excellent presentation of a difficult subject. I admire his courage in attempting this colossal task. He has made it not merely difficult, but practically impossible for me to formulate any sort of a worthwhile discussion. He has presented so skillfully prepared a brief for the defense that even the most astute legal minds among you will be taxed in what will prove to be a futile effort to challenge Dr. Sulzberger's contentions. I agree with practically everything that he has said. Our concept of allergy and what should clinically be accepted as allergic is indeed broad and covers practically every branch of medicine and surgery, but as Dr. Sulzberger has so aptly

insisted, this in no way modifies our concept of this phenomenon. It is only the repeated attempts at coining new words to apply to one particular group or another that tends to weaken the structure on which we stand. It adds to our confusion rather than serving to simplify our understanding.

Zinsser, Ratner, Kolmer, Peshkin, and others have repeatedly stated that a close similarity between human and animal hypersensitiveness must be recognized. There is no advantage and no logical grounds for introducing or retaining the term atopic. I agree with Dr. Sulzberger in desiring to adhere to von Pirquet's original definition and should prefer to use the term allergy as all inclusive, using other descriptive phrases or names as a means of further

If the shouted voice is heard, it means the hearing loss is not over ninety db, and vice versa.

Note The examiner does not know exactly how sounds appear to a patient because every ear is an entity as to the quality of reception.

The *phonograph audiometer (4A)* is a very satisfactory instrument for speech tests because it is calibrated for intensity. It is most valuable for group testing. Its use of figures opens up more possibilities for guessing than would unrelated words.

Its limitations are that it is expensive, bulky, its records break and wear out so that upkeep is considerable, its intensity is limited.

Tuning forks

If properly designed, manufactured, and standardized, tuning-forks are precision instruments. They are cheap, easily transported, and there is no upkeep.

Disadvantages are that one or two tests per fork are apt to be misleading. According to the law of chances, four runs with each fork are necessary to give twice the accuracy of a single run. This means that for the five forks of the Hartman set at least twenty runs must be made at each complete testing. On the average this will consume about an hour. This is more time than can usually be given.

There are limitations in that there is no provision for the upper parts of the frequency or intensity ranges. The latter limitation is important only in severe deafness. Unless standardized and calibrated, the tests are not comparable with tests made by others using different forks. Results will differ with make of fork, technic, and even between two tests made by the same tester.

Tuning-forks die down on the average more quickly directly with frequency. The lower forks die down slowly, (only about one quarter to one decibel a second) whereas the higher forks (1024, 2048) have a decrement of two to four decibels a second, depending upon the make used and the condition of the fork. The high forks die down so quickly that it is difficult to make accurate measurements of the time they are heard. The decrement rate of a fork used for bone conduction, is greater than when it is used for air conduction because of the damping effect

of the contact with the head. The use of forks usually entails too many variables for precise measurements.

The author believes his method of alternate placement is the most satisfactory way of testing the hearing with tuning forks. This method will be described under "Examiner."

1A and 2A Western Electric (and other) audiometers have wide range of frequencies and intensities, a steady sufficiently pure tone which may be applied again and again and sustained at any desired intensity. There is no gradual fading out as in tuning-forks, there is conservatism of time and effort of examiner and patient and avoidance of fatigue because of the short time the patient is required to listen.

Air conduction and bone conduction may be measured in the same units (sensation units or decibels).

(A decibel "db" or sensation Unit "SU" is the standard unit of measure for sound intensity. One decibel is the minimum amount of loudness *change* that can be sensed as such. It is a relative term. The audiogram is made on a logarithmic scale, etc.)

There are some disadvantages. Audiometers are expensive and cumbersome, there is some upkeep on account of breakage, and the bone conduction receiver is often inefficient, unstable, and fragile. In the 2A audiometer, the intensity scale is not much greater than it is in tuning-forks. The 1A audiometer is very expensive but the most satisfactory instrument yet produced for precision measurements of the hearing acuity. Maintenance of accurate calibration is imperative for all instruments.

Patient

The great majority of patients are cooperative, attentive, and fairly accurate observers irrespective of their ability or training or of their degrees of deafness.

Some are not so and, try as they may, accurate observation appears for them to be difficult or impossible. This may be due to age, insufficient vocabulary, nervousness, stupidity, lip reading ability, or familiarity with the voices, words, phrases or mannerisms of the speaker or examiner. It is frequently due to the inexperience of the examiner.

PRECISION HEARING TESTS

Interpretations in the Light of Recent Research

EDMUND PRINCE FOWLER, M D, *New York City*

The primary objective in testing the hearing is to obtain an accurate picture of hearing acuity. Obviously, an inaccurate picture may lead one far astray not only as to the hearing but as to the diagnosis of ear disease, or any disease causing deafness. It is unfortunately quite the custom to obtain an inaccurate, a blurred or a partial picture.

The hearing tests are only one of the aids, not the only aid or the only tests, used for diagnosis. One may often make a diagnosis of ear conditions with very superficial or even without any hearing tests, but I assert that without precision tests fully fifty per cent of all diagnoses are faulty as to differentiation of lesions and of course quantitatively worthless, prognostically of little value, and therapeutically of little use.

Obstacles to accurate testing may arise from any or all of the three elements necessary to every test, i.e., the apparatus, the patient, and the examiner.

Apparatus

The testing room should be sound-proofed, or so protected that outside noise is not heard by the patient. In the usual quiet ward of a hospital, noise may cut down the hearing fifteen to twenty decibels below its true level.

For distance testing, the room should be about thirty feet long with sound damped walls, far enough apart to prevent the interference from sound reflections as in pipes or conduits. For testing at short distances, (within three or four feet of the patient) it is of course not necessary to have the large room.

The noise level should be below the patient's minimum audibility level.

Sound sources

The watch, metronome, bunch of keys, snapping fingers, etc., may be used only to test the hearing for their own particular tone or noise, and depend upon

distance measurements. They are crude and practically useless for determining the hearing acuity and for diagnostic purposes.

Monochord and whistles have a wide range of frequencies but are not calibrated for intensity and therefore useless except to determine whether or not the ear hears the sounds produced. One cannot determine how well the ear hears them. The Galton and Galton-Edelmann whistles are open to the same criticisms, and often emit several sounds besides their true tone. It is difficult to tell which sound the patient is hearing.

I shall not discuss further any of the above mentioned instruments at this time because they are *relatively unreliable and obsolete for precision testing.*

The voice as faint or loud whisper, and as faint, moderate and loud voice, may be approximately calibrated and is then a more useful sound source than most of the instruments heretofore mentioned and better than any of them for determining the acuity of hearing for speech. Attention is called to the fact that threshold intensities do not give as accurate a picture of the hearing acuity for speech as does the articulation percentage using louder sounds. No one except for special reasons listens to threshold intensities. I shall discuss this in more detail anon.

Properly used the voice may be calibrated not only for each examiner but with loose approximation as between examiners.

If the faint whisper is heard at 30", it means the hearing loss is not over thirty db, and vice versa.

If the loud whisper or faint voice is heard, it means the hearing loss is not over forty-five db, and vice versa.

If the moderate voice is heard, it means the hearing loss is not over sixty db, and vice versa.

If the loud voice is heard, it means the hearing loss is not over seventy-five db, and vice versa.

Instructional talk at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1936

The *Rinne test* is perhaps the most popular of all the older devices for differentiating nerve from obstructive lesions. If one's forks be carefully calibrated and used with proper technic, Rinne is unnecessary. It is often uncertain for diagnostic purposes and of practically no value quantitatively. A positive Rinne means that the fork is heard before the ear after it has ceased to be heard upon the mastoid. A negative Rinne means that the fork is heard on the mastoid after it has ceased to be heard before the ear. These results vary in different degrees with frequency and with forks. One may obtain a difference between the two modes of placement, but not a ratio, because the rate of decrement is quite different for a fork before the ear and a fork in contact with the head.

When using the voice, tuning-forks, or other sound sources, be careful to have the patient's eyes closed so he cannot see the manipulation of the sound source. If the patient observes to which ear a fork is applied, there is no need for him to listen to determine in which he is supposed to hear it. (Test with eyes closed.) Inconsistent responses will lead one to suspect errors. The patient may misinterpret feeling for hearing. My 128, 256, and 512 forks may be felt on the fingers at practically the same intensities as for minimum audibility by bone conduction on the mastoid process. (Explain the necessity of distinguishing feeling from hearing.)

Few examiners use a standard blow for activating forks. In my opinion, the best blow is obtained by striking the fork on a hockey pock or rubber heel, with what I call a maximum blow, that is, a blow sufficiently strong to produce the loudest tone of which the fork is capable, and yet not so loud as to damage the fork. If this is done, the fork will settle down to a steady decrement within a fraction of a second, and the longest possible vibration time will have been obtained.

Without any change in the hearing, the functional tests may vary considerably from time to time owing to variations in the three elements we are discussing, namely, instruments, patient, and examiner.

In my opinion there is only one way to obtain accurate and universally under-

standable tuning-fork data. I introduced this method fifteen years ago. It is called the complete alternate placement method, and is carried out as follows:

Use calibrated forks. (The method of calibrating tuning-forks is by dividing the loss of hearing in seconds with the loss in decibels, or vice versa, as determined by testing a markedly deafened ear at the same frequencies on a standard audiometer. This will determine the number of seconds required for one decibel loss or the number of db per second of time loss as the case may be.) Hold the shank of the fork between the thumb and forefinger with the prongs in a vertical plane, and strike the tip of one prong on a hockey pock with sufficient force to put the fork into maximum vibration. Stand in front of the patient (whose eyes are closed) and present the fork before the ear at a distance of one inch. Hold it in this position not over one and one-half seconds and then place the end of the shank against the mastoid process at a point where it is heard best, and allow it to contact the mastoid quickly and firmly enough to elicit the maximum sensation (not over one and one-half seconds). The best position is usually just behind and a trifle above the external auditory canal. Be careful to hold the pinna forward so that it does not touch the fork or close the meatus.

Change one position of the fork from the mastoid to before the ear every two and one-half seconds (five seconds for the complete cycle of placements) and alternate these placements until the sound ceases to be heard both by air conduction and bone conduction. This causes the fork to die down at approximately the same rate during each five second interval of time.

Start a two hand stop watch coincidentally with the activating blow. Both hands will be set in motion. At every placement of the fork the patient is to answer "yes" if he hears it and "no" if he does not. Or, may be better still, to answer "yes" if he hears it and say nothing if he does not hear it. At the first placement at which the patient fails to answer "yes" push the button which stops one hand of the watch. This gives the number of seconds the fork was heard by air conduction or bone conduction depending upon which mode of placement first coincided with failure to hear it. Continuing the placements as before pressing the other button stopping the other hand when the patient again ceases to answer "yes." This gives the number of seconds the fork was heard by air or bone conduction as the case may be. The last timing

Quality of speech is variable in every one, but on the part of the hard of hearing the apparent lack of ability for exact mimicry may not be due to inability of speech production but to an abnormal sensing of the sounds heard. In other words, sounds may appear different to different ears, and consequently when mimicked are reproduced differently, not necessarily as spoken by the examiner.

Impacted cerumen, fluids or foreign bodies in the meatus or middle ear may lower the hearing up to fifteen to twenty db.

Marked deafness often makes it difficult to procure sufficient intensity for the patient to hear the sounds used for testing, and to mask out one ear while testing the other.

Tinnitus causes uncertainty by disturbing and masking effects, whether it is in one or in both ears.

Pain or tenderness about the ear may prevent testing with air or bone conduction receivers.

Fatigue of body, mind or of the ear, lowers acuity of hearing.

Methods for overcoming these difficulties will be described under "Examiner."

The usual hearing tests appear accurate for threshold sounds. They do not necessarily tell us how the ears hear sounds louder than threshold and yet it is the louder than threshold sounds to which our ears are accustomed to hear conversation. This subject will be taken up under "Examiner."

Examiner

The chief obstacle to exact testing is an examiner who is careless, hurried, uninformed, insufficiently trained or who uses obsolete methods.

Tuning forks

Every otologist is familiar with the classical tuning-forks tests. I shall speak of them but briefly at this time. Tuning-forks have one great defect, they constantly die down, which necessitates the patients listening to a constantly diminishing tone. This is conducive to inaccurate observations.

The examiner should know the advantages, disadvantages, and limitations of the different tests, and the different

methods of recording in numbers, fractions, and graphs.

The examiner should know (1) the fundamentals of the physics of sound as applicable to otologic practice, (2) that sound waves may be below the threshold of hearing, at threshold, above the threshold and at or above the threshold of feeling, (3) that by bone conduction there is on the average only about four decibels impedance through the skull so that the ear not being tested must be masked to eliminate it as a disturbing factor in Monaural B C tests, (4) that by air conduction when the loudness necessary for hearing approaches fifty decibels above that required for the other ear, masking must be employed to determine which ear is really hearing the sound, (5) that unless bone conduction is obtained at the same frequencies as air conduction, the audiogram picture may be very misleading, and that great care is necessary to avoid air conduction with the higher frequencies. It is usually impossible to do this with the higher forks, and difficult even with a bone conduction receiver. Do not touch the ear with fork or bone conduction receiver. Do not close the meatus.

The Weber test is not properly a test for hearing acuity but is used solely for the purpose of determining whether monaural deafness is of nervous or obstructive origin. It may be elicited by the use of tuning-forks or the audiometer bone conduction receiver, and in other ways. It is of value in marked unilateral deafness, if it corroborates other findings. Weber may be referred to one ear using a fork of one frequency and to the opposite ear using a fork of another frequency. It may even change from one ear to the other during the placement of a single fork. It is unnecessary—even superfluous—if modern methods are used.

The Schwabach test has defects inherent in most tuning-fork tests (Faulty forks, faulty calibration, difficult technique, audibility by air conduction).

The Gelle test is now used but seldom and is of questionable value. When positive, it is supposed to indicate stapes mobility, when negative stapes ankylosis. It is not specific for stapes ankylosis because other impedences in the middle ear may give negative results.

The Rinne test is perhaps the most popular of all the older devices for differentiating nerve from obstructive lesions. If one's forks be carefully calibrated and used with proper technic, Rinne is unnecessary. It is often uncertain for diagnostic purposes and of practically no value quantitatively. A positive Rinne means that the fork is heard before the ear after it has ceased to be heard upon the mastoid. A negative Rinne means that the fork is heard on the mastoid after it has ceased to be heard before the ear. These results vary in different degrees with frequency and with forks. One may obtain a difference between the two modes of placement, but not a ratio, because the rate of decrement is quite different for a fork before the ear and a fork in contact with the head.

When using the voice, tuning-forks, or other sound sources, be careful to have the patient's eyes closed so he cannot see the manipulation of the sound source. If the patient observes to which ear a fork is applied, there is no need for him to listen to determine in which he is supposed to hear it. (Test with eyes closed.) Inconsistent responses will lead one to suspect errors. The patient may misinterpret feeling for hearing. My 128, 256, and 512 forks may be felt on the fingers at practically the same intensities as for minimum audibility by bone conduction on the mastoid process. (Explain the necessity of distinguishing feeling from hearing.)

Few examiners use a standard blow for activating forks. In my opinion, the best blow is obtained by striking the fork on a hockey pock or rubber heel, with what I call a maximum blow, that is, a blow sufficiently strong to produce the loudest tone of which the fork is capable, and yet not so loud as to damage the fork. If this is done, the fork will settle down to a steady decrement within a fraction of a second, and the longest possible vibration time will have been obtained.

Without any change in the hearing, the functional tests may vary considerably from time to time owing to variations in the three elements we are discussing, namely, instruments, patient, and examiner.

In my opinion there is only one way to obtain accurate and universally under-

standable tuning-fork data. I introduced this method fifteen years ago. It is called the complete alternate placement method, and is carried out as follows:

Use calibrated forks. (The method of calibrating tuning-forks is by dividing the loss of hearing in seconds with the loss in decibels, or vice versa, as determined by testing a markedly deafened ear at the same frequencies on a standard audiometer. This will determine the number of seconds required for one decibel loss or the number of db per second of time loss as the case may be.) Hold the shank of the fork between the thumb and forefinger with the prongs in a vertical plane, and strike the tip of one prong on a hockey pock with sufficient force to put the fork into maximum vibration. Stand in front of the patient (whose eyes are closed) and present the fork before the ear at a distance of one inch. Hold it in this position not over one and one-half seconds and then place the end of the shank against the mastoid process at a point where it is heard best, and allow it to contact the mastoid quickly and firmly enough to elicit the maximum sensation (not over one and one-half seconds). The best position is usually just behind and a trifle above the external auditory canal. Be careful to hold the pinna forward so that it does not touch the fork or close the meatus.

Change one position of the fork from the mastoid to before the ear every two and one-half seconds (five seconds for the complete cycle of placements) and alternate these placements until the sound ceases to be heard both by air conduction and bone conduction. This causes the fork to die down at approximately the same rate during each five second interval of time.

Start a two hand stop watch coincidentally with the activating blow. Both hands will be set in motion. At every placement of the fork the patient is to answer "yes" if he hears it and "no" if he does not. Or, may be better still, to answer "yes" if he hears it and say nothing if he does not hear it. At the first placement at which the patient fails to answer "yes" push the button which stops one hand of the watch. This gives the number of seconds the fork was heard by air conduction or bone conduction depending upon which mode of placement first coincided with failure to hear it. Continuing the placements as before pressing the other button stopping the other hand when the patient again ceases to answer "yes." This gives the number of seconds the fork was heard by air or bone conduction as the case may be. The last timing

will always coincide with that mode of placement of the fork which predominated. In deducting these from the number of seconds the fork is heard by the normal ear, the examiner will know the number of seconds loss by air conduction, and the number of seconds loss by bone conduction. The fork having been calibrated by the alternate method of placement, it is simple to figure the hearing loss in decibels, and to construct an audiogram in the same way as when using an audiometer. The examiner has obtained in standard units of measure the hearing loss for air conduction, and for bone conduction, and he has only used one run of the fork to obtain both of these. By no other method is it possible to do this with tuning-forks.

You will notice that I said to hold the fork before the ear at a distance of one inch. This is done so that if the patient does not respond at once as the fork is placed before the meatus, it may be moved quickly about half an inch closer to the ear to give the patient a second chance to hear the sound. If the fork were held closer to the ear, the examiner would not have the distance necessary to enable him to bring the fork closer, without endangering contact with the skin of the ear or the hair, either of which would damp the intensity of vibration and spoil the test.

For the lower frequencies, the method as described is very accurate because the loss in decibels per second is, for well-made lower forks, on the average but one second, or less.

For the higher frequencies, the loss in decibels per second is nearer two to four. Therefore, if our alternating placements are made every two and one-half seconds, there is a five second interval between mastoid placements and a five second interval between the "one inch from the meatus" placements. This number of seconds between the patient's opportunities to listen, means that a fork will have died down some ten to twenty decibels between each placement. This is too great a number for accuracy, and therefore, for the higher forks I advocate a greater speed in alternating placements, namely, one and one-half seconds (three seconds for each cycle). Of course, the higher forks should be calibrated using this speed of alternate placement. By carrying out the tests in this manner, it is

surprising how accurately the results will correspond to the audiometric data obtained by a properly calibrated audiometer.

There are several advantages to this method of using the tuning-forks

- 1 Standard maximum blow

- 2 Possibility of calibrating forks in the same units of measure for air conduction and bone conduction

- 3 Saving one-half the time required to take air conduction and bone conduction separately

- 4 Prolonging the time the fork can be heard, and lessening fatigue, by the intermittent placements

- 5 Overcoming the disadvantage of the constantly lessening intensity of the fork by holding it an inch away from the meatus thus giving room to bring it quickly nearer to the ear if the patient does not at once sense the tone. (*Note* Near minimum audibility the gain in intensity by moving the fork a half inch closer to the head is, owing to the lag in making this change in position, not over three or four decibels. This means that the patient is really getting a chance to listen again to the same intensity as when the fork was first placed an inch from the head.)

To be accurate, four runs should be made for each fork used. If pressed for time, I advise using only the 256, 1024, and 2048 forks. This will give a more dependable picture of the hearing, than if all five of the Hartman forks were used once or even twice.

I now use this test only to supplement and check up on audiometer testing. It takes at least three or four times as long as audiometer testing.

The examiner should be familiar with the audiometer and understand audiograms and audiometric measurements. In the very near future, we shall be able to purchase excellent audiometers at a third to a quarter of the present prices and this will do more for universal understanding of functional tests than anything in the past. The technic of using the audiometer is easily acquired, but no otologist should accept without critical scrutiny the measurements obtained by his nurse or technician. The most obvious errors will escape his notice unless he personally knows how to detect faulty measurements.

If tinnitus interferes with accuracy, increase the loudness fifteen or twenty

decibels above the apparent threshold of hearing for the ear being examined. This will tend to exclude the tinnitus as a masking sound to the frequency being tested. Balance this loudness against a loudness in the opposite ear of the same number of decibels above its threshold. If the balance, as indicated by the number of decibels above threshold, maintains the same ratio between the two ears as at the minimum audible intensities, the threshold measurements may be considered as accurate. If the balance is changed, the threshold measurements were inaccurate and should be changed accordingly.

The following points may be of interest

- 1 Caution the patient not to press the light button when he hears only audiometer switch noises

- 2 Always allow the patient to hear the tone distinctly before approaching the threshold intensity so that he may be certain of the tone to which he is to respond.

- 3 Approach the threshold both from above and below, without using the interrupter, then while using the interrupter

- 4 I have always favored double receivers with rubber caps not only because they eliminate ten to fifteen decibels of outside noise, but because they enable you to switch the sound from ear to ear, and if the patient cannot tell in which ear he hears the threshold intensities, the examiner must suspect the accuracy of his response

- 5 Do not ignore the practice factor. On the average, second tests are a little better than the first tests

- 6 Spread or scattering observations made at a single frequency will indicate inaccuracies introduced by apparatus, patient or examiner

- 7 With differences of more than forty decibels between the two ears, suspect cross audition, and use masking in the better ear for air conduction. Bone conduction cannot be accurately obtained for abnormal ears without masking the ear not being tested.

Masking

Masking is one of the most important adjuncts in the functional examination of hearing. It is almost universally neglected, even when using bone conduction, with which it is imperative to mask the opposite ear in order to be assured that only one ear is hearing the testing sound, even when the worse ear is markedly

down by air conduction. *Masking should always be applied first to both ears and with sufficient intensity to mask out the ear not to be tested.* It requires at least forty db less intensity to mask air conduction than bone conduction because air conduction sounds reach the opposite ear with a loss of forty to fifty decibels. Only in this way may one make certain of efficient exclusion of the ear not to be tested.

A simple improvised method for masking one ear is to blow a stream of air from the lips into and across the external auditory meatus of the patient's ear. A binaural improvisation is to use an ordinary stethoscope in the patient's ears and to blow into and across the bell of the stethoscope during each application of the sound in front of the ear or upon the skull. For monaural masking by this method, remove the stethoscope on the side that is to be tested and carry out the blowing as before. I proposed this simple method some twenty years ago not only for masking but as an aid in detecting malingering. If the subject has hearing, it is difficult for him not to alter the loudness of his voice as the intensity of the masking is increased and diminished, and as the loudness is changed from one side of the stethoscope to the other. A sure sign of hearing is after masking with slowly increasing intensities, to notice patient's voice increase in loudness coincidentally with the masking noise. Monaural and binaural malingering may be detected in this manner.

If the stethoscope is connected through a "Y" piece with rubber tubing to a source of compressed air, one has a most efficient and constant intensity masking apparatus. It is well to cut some slits in the tubing near the source of air supply so that noise may be produced by the air rushing by these slits, as well as by its escape at the ear pieces, because to some people the latter is uncomfortable. In a normal ear, this method will mask the loudest shouted voice, and pure tones by air conduction up to ninety or more decibels intensity. It is more difficult to mask bone conducted sounds than air conducted sounds. It is more difficult to mask an ear with pure conductive or mechanical deafness than an ear with pure nerve deafness because the former

has good bone conduction and the latter, in order to be diagnosed as nerve deafness, must have lowered sensitivity by bone conduction

We know of no way to make, with certainty, a diagnosis of nerve deafness without a loss of hearing by bone conduction sounds, but unless the opposite ear is devoid of all hearing, it should be sufficiently masked to insure accurate observations of bone conduction by the ear being tested

I am aware of the skepticism in regard to the measurements made by bone conduction, but we must do the best that we can with the means at hand and, as I have said before, this is the only way that we have to determine nerve deafness. Next month, at the meeting of the American Otological Society, I shall present a new method for aiding in diagnosis. By this method, conductive lesions, nervous lesions, and both of these coincidentally, show differentiating characteristics. It is inadvisable to discuss this further at this time except to state that these new methods of approach to the physiology and pathology of the ear, substantiate with certain possible exceptions the findings by bone conduction.

In making audiometric measurements for the purposes of diagnosis, it is not

always necessary to examine at all the frequencies. One of the lower tones (say 256) a middle tone (1024), and the higher tones, 2048, 4096, and 8192 will, ninety-nine times out of one hundred, be quite sufficient if obtained with proper technic. All but 8192 should be tested by bone conduction.

The custom of stating hearing ability in percentage is to be discouraged. I was mistaken when cooperating in the production of the first audiometer, to insist upon setting up a percentage scale in addition to the sensation or decibel scale. There is, strictly speaking, no way of figuring a percentage loss of hearing because there is no true upper limit. The assumed upper limit at the threshold of feeling is, of course, artificial because it is not the upper limit of sound intensity. Sounds much louder than this may be heard. Instead of stating that one is down such and such a percentage in hearing, it is more accurate to say that one is down so many units at a given frequency, or the average of so many units at such and such frequencies, or that the hearing loss is equivalent to a loss in distance estimated approximately by figuring one-third to one-half of the distance for every ten decibel loss.

ROCHESTER S GALAXY OF SPEAKERS

LEADERS IN AMERICAN and Canadian medical fields will be brought to Rochester as speakers before the Rochester Academy of Medicine this season, Dr Willis E Bowen, president, announces.

First was Dr Russell M Wilder, professor of medicine at the Mayo Clinic, Rochester, Minn, who came on Oct. 1 and spoke on "The New Insulin."

Dr Arthur C Christie, professor of clinical pathology, School of Medicine, Georgetown University, and president of the Fifth International Congress of Radiology, at the November meeting on "Cancer of the Lip, Mouth and Throat, Its Diagnosis and Treatment."

For the December meeting, the speaker will be Dr Ralph H Major, professor internal medicine at the University of Kansas School of Medicine, authority on high blood pressure. He will talk on "Observations on Lipoid Nephrosis."

Dr Paul D White, assistant professor of medicine at Harvard University, will discuss "Cardiac Problems in General Practice," before the group Jan 7.

At the February meeting Dr George Crile, director of the Cleveland Clinic, speaks on essential hypertension.

Speaking at the March session will be Dr Edward W Archibald, consulting physician, Royal Victoria Hospital and professor and director of surgery at McGill University, Montreal. He will talk on "How Can Modern Lung Surgery Help the General Practitioner?"

Dr Edward S Godfrey Jr, New York State commissioner of health, will be the speaker at the April meeting, discussing "The Meaning of Public Health."

Dr Henry F Helmholtz, professor of pediatrics, University of Minnesota, comes May 6 to address the group on treatment of pyogenic infections in children.

Symposium: Industrial Diseases and Accidents to the Hand

DERMATOSES OF THE HANDS

B J SLATER, M D, *Rochester*

In discussing the subject, "Dermatoses of the Hands," no claim is made that we are approaching this subject from the point of view of an experienced dermatologist. Our experience is that of a physician in industry who has for seventeen years treated various skin conditions, many of which have arisen out of and during the course of employment. During this period of time, we of course, have come in contact with many cases, in some of which the industrial origin has been established, while in others no etiological factors have been found.

Broadly speaking, there is no field of medicine in which there is greater need for research than dermatology. This becomes particularly true as an ever-increasing number of chemicals are finding their way into industrial use. Certain facts have been known for years in regard to the dermatoses, the exact nature of which is not understood. The exact physiological reason, for example, as to why blondes are more susceptible than brunettes is not understood, neither is the broad question of idiosyncrasy to chemicals, any more than it is understood why certain individuals are hyper-susceptible to various drugs.

Recently, the sulphur content of the skin has been given study, and perhaps this may offer some explanation for increased susceptibility. The peculiar photosensitivity of certain individuals is also of intense interest, and certainly explains some otherwise baffling cases.

Dr Alice Hamilton has strongly urged the establishment of an Industrial Institute in which various phases of industrial toxicology would be studied. Of these, dermatological researches could easily occupy a predominant place. If the fundamental reasons underlying idiosyncrasy and susceptibility could be established, great steps could be taken in protecting

certain groups of individuals. The problem is almost too large for one industry to undertake, when viewed in its broader aspects. In America, the Harvard Medical School has made notable contributions on various subjects of industrial interest, and has published a very interesting magazine dealing entirely with industrial health problems. It is a healthful sign to see the increased interest which medical schools are taking in such problems and it is safe to say that the future will see a greater activity in this direction.

No effort will be made here to describe the physiology or anatomy of the skin. This has been done before in many interesting articles. To those, however, who are anxious to study the basic principles which rule the skin irritants in industry, we especially commend R. Prosser White's address before the 6th National Congress for the Study of Accidents and Illnesses, on the various fundamental reactions of the skin to different irritants, wherein an attempt is made to physiologically interpret the reaction of the skin to various offending substances.

The introduction of the patch test has been of the greatest assistance in isolating the offending agent and has proved of tremendous value to industrial physicians and to others, and has been to industrial dermatologists, what the Wassermann reaction has been to syphilologists. There is no question but that by means of this test, the physician has been able to isolate various chemicals which were hitherto unsuspected.

To those who are interested in the broad general subject, we recommend R. Prosser White's excellent text book¹. Recently, medical literature has presented several fine articles bearing on this subject, for example, Osborne and Putnam² have written a very instructive article. The authors have shown with what metic-

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

has good bone conduction and the latter, in order to be diagnosed as nerve deafness, must have lowered sensitivity by bone conduction

We know of no way to make, with certainty, a diagnosis of nerve deafness without a loss of hearing by bone conduction sounds, but unless the opposite ear is devoid of all hearing, it should be sufficiently masked to insure accurate observations of bone conduction by the ear being tested

I am aware of the skepticism in regard to the measurements made by bone conduction, but we must do the best that we can with the means at hand and, as I have said before, this is the only way that we have to determine nerve deafness. Next month, at the meeting of the American Otological Society, I shall present a new method for aiding in diagnosis. By this method, conductive lesions, nervous lesions, and both of these coincidentally, show differentiating characteristics. It is inadvisable to discuss this further at this time except to state that these new methods of approach to the physiology and pathology of the ear, substantiate with certain possible exceptions the findings by bone conduction.

In making audiometric measurements for the purposes of diagnosis, it is not

always necessary to examine at all the frequencies. One of the lower tones (say 256) a middle tone (1024), and the higher tones, 2048, 4096, and 8192 will, ninety-nine times out of one hundred, be quite sufficient if obtained with proper technique. All but 8192 should be tested by bone conduction.

The custom of stating hearing ability in percentage is to be discouraged. I was mistaken when cooperating in the production of the first audiometer, to insist upon setting up a percentage scale in addition to the sensation or decibel scale. There is, strictly speaking, no way of figuring a percentage loss of hearing because there is no true upper limit. The assumed upper limit at the threshold of feeling is, of course, artificial because it is not the upper limit of sound intensity. Sounds much louder than this may be heard. Instead of stating that one is down such and such a percentage in hearing, it is more accurate to say that one is down so many units at a given frequency, or the average of so many units at such and such frequencies, or that the hearing loss is equivalent to a loss in distance estimated approximately by figuring one-third to one-half of the distance for every ten decibel loss.

ROCHESTER'S GALAXY OF SPEAKERS

LEADERS IN AMERICAN and Canadian medical fields will be brought to Rochester as speakers before the Rochester Academy of Medicine this season, Dr Willis E Bowen, president, announces.

First was Dr Russell M Wilder, professor of medicine at the Mayo Clinic, Rochester, Minn, who came on Oct. 1 and spoke on "The New Insulin."

Dr Arthur C Christie, professor of clinical pathology, School of Medicine, Georgetown University, and president of the Fifth International Congress of Radiology, at the November meeting on "Cancer of the Lip, Mouth and Throat, Its Diagnosis and Treatment."

For the December meeting, the speaker will be Dr Ralph H Major, professor internal medicine at the University of Kansas School of Medicine, authority on high blood pressure. He will talk on "Observations on Lipoid Nephrosis."

Dr Paul D White, assistant professor of medicine at Harvard University, will discuss "Cardiac Problems in General Practice," before the group Jan. 7.

At the February meeting Dr George Crile, director of the Cleveland Clinic, speaks on essential hypertension.

Speaking at the March session will be Dr Edward W Archibald, consulting physician, Royal Victoria Hospital and professor and director of surgery at McGill University, Montreal. He will talk on "How Can Modern Lung Surgery Help the General Practitioner?"

Dr Edward S Godfrey Jr, New York State commissioner of health, will be the speaker at the April meeting, discussing "The Meaning of Public Health."

Dr Henry F Helmholtz, professor of pediatrics, University of Minnesota, comes May 6 to address the group on treatment of pyogenic infections in children.

Symposium: Industrial Diseases and Accidents to the Hand

DERMATOSES OF THE HANDS

B J SLATER, M D, *Rochester*

In discussing the subject, "Dermatoses of the Hands," no claim is made that we are approaching this subject from the point of view of an experienced dermatologist. Our experience is that of a physician in industry who has for seventeen years treated various skin conditions, many of which have arisen out of and during the course of employment. During this period of time, we of course, have come in contact with many cases, in some of which the industrial origin has been established, while in others no etiological factors have been found.

Broadly speaking, there is no field of medicine in which there is greater need for research than dermatology. This becomes particularly true as an ever-increasing number of chemicals are finding their way into industrial use. Certain facts have been known for years in regard to the dermatoses, the exact nature of which is not understood. The exact physiological reason, for example, as to why blondes are more susceptible than brunettes is not understood, neither is the broad question of idiosyncrasy to chemicals, any more than it is understood why certain individuals are hyper-susceptible to various drugs.

Recently, the sulphur content of the skin has been given study, and perhaps this may offer some explanation for increased susceptibility. The peculiar photosensitivity of certain individuals is also of intense interest, and certainly explains some otherwise baffling cases.

Dr Alice Hamilton has strongly urged the establishment of an Industrial Institute in which various phases of industrial toxicology would be studied. Of these, dermatological researches could easily occupy a predominant place. If the fundamental reasons underlying idiosyncrasy and susceptibility could be established, great steps could be taken in protecting

certain groups of individuals. The problem is almost too large for one industry to undertake, when viewed in its broader aspects. In America, the Harvard Medical School has made notable contributions on various subjects of industrial interest, and has published a very interesting magazine dealing entirely with industrial health problems. It is a healthful sign to see the increased interest which medical schools are taking in such problems and it is safe to say that the future will see a greater activity in this direction.

No effort will be made here to describe the physiology or anatomy of the skin. This has been done before in many interesting articles. To those, however, who are anxious to study the basic principles which rule the skin irritants in industry, we especially commend R. Prosser White's address before the 6th National Congress for the Study of Accidents and Illnesses, on the various fundamental reactions of the skin to different irritants, wherein an attempt is made to physiologically interpret the reaction of the skin to various offending substances.

The introduction of the patch test has been of the greatest assistance in isolating the offending agent and has proved of tremendous value to industrial physicians and to others, and has been to industrial dermatologists, what the Wassermann reaction has been to syphilologists. There is no question but that by means of this test, the physician has been able to isolate various chemicals which were hitherto unsuspected.

To those who are interested in the broad general subject, we recommend R. Prosser White's excellent text book.¹ Recently, medical literature has presented several fine articles bearing on this subject, for example, Osborne and Putnam² have written a very instructive article. The authors have shown with what metic-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

ulous care the subject must be pursued, and have by various illustrations shown the success which awaits the careful investigator. This article is an invitation to all physicians interested in the subject, to be painstaking.

Levin³ has written another very interesting article which contains a good classification of skin irritants. Similarly, Doctors Eller and Schwartz⁴ have written a very comprehensive article on the industrial dermatoses, together with a very comprehensive classification and bibliography. Were it not for the fact that these classifications are so thorough, we might submit a classification in this article. They, however, acquaint the practitioner with the broad general background of the subject.

From the compensation point of view there is scarcely any subject which offers greater difficulty in establishing causal relationship, than the dermatoses. When one realizes the number of agents in and out of industry which may cause an irritation of the skin, it is not to be wondered that referees are baffled in trying to decide on the equity of a particular case. As a general rule, the attitude appears to be that if a person suffers from a dermatitis, and the substance with which he is working is capable of producing the dermatitis, it is assumed that the one produces the other. Lacking specific information on the subject, it is difficult to see how the referee could adopt another attitude.

It is, of course, a well-known fact that many people who are exposed to no known hazard, at times present baffling dermatoses of the hands. As a matter of fact, two executives who are exposed to no known hazard, have presented the most stubborn cases of dermatoses of the hands. If these two individuals were exposed to solvents, carbon tetrachloride, alkalis, acids, and many other substances they would, without question, be diagnosed as industrial or occupational dermatitis. As a matter of fact, no such hazard exists and the exact etiological factor is unknown. In this connection, Becker's⁵ excellent article is of great value. The fact that an employee may be handling a substance which is capable of producing a dermatitis, is not of itself sufficient reason why the physician should in every instance stop

his investigation when such facts are brought to light. In other words, every case is entitled to a thorough investigation, and the practitioner should seek as his fundamental guide, the establishment of the truth, no matter what its sociological or industrial bearing may be. It is not good medicine to assume that every skin irritation which arises in medical practice is due to an industrial process, all other opinions to the contrary notwithstanding. Similarly, all neuroses that arise in industry are not due to trauma, or to industry.

We are advised that dermatoses constitute the greater number of industrial diseases in certain states. Comparable figures furnished by Dr R S McBurney⁶ show that in New Jersey, Mass., Conn., and Ohio, the industrial dermatoses led the list of occupational diseases. It is generally estimated that from two to sixty per cent of all dermatoses are industrial in origin. It is further estimated that one per cent of all workers suffer from some form of occupational dermatitis. It has not been our experience that dermatitis forms a large percentage of the cases reported in the average industrial clinic, and we are not led to believe that the higher figure of sixty per cent expresses the truth as regards industrial origin of these dermatoses. Under the present New York law, any substance which causes any disease is compensable if disability arises from its use. There is, of course, no question of carelessness or contributory negligence involved.

Dr Anderson in discussing Osborne and Putnam's paper, points out the fact that occasionally a physician prescribes mercury for a patient with the result that the patient develops a mercurial dermatitis. A physician in this instance would, of course, feel very badly if he were legally penalized because of the fact that his patient showed an idiosyncrasy to the mercury. As a matter of fact, industries are penalized very often under exactly the same circumstances. Ninety-nine workmen may be exposed to a certain chemical and show no irritation of the skin. The hundredth one, however, may prove to be susceptible. If there is disability, compensation naturally follows.

There is no question but that this type

of disease is ever on the increase. This may be due to the fact that physicians are becoming more familiar with the law, or they may be becoming more accurate in their diagnosis.

Figures reported by the State Department of Labor show an increasing amount of dermatoses. It is doubtful, however, if the number reported represents the actual number in industry, in many instances the disability is not great, and certainly not disabling. Where there is no loss of time, and no compensation paid, the disease will probably not be reported to the Industrial Commissioner, even though the law requires that it should be. On the other hand, proneness of physicians to favor the workmen at the expense of the industry may frequently result in cases being reported in which further study would have shown them not to have been of industrial origin.

The ubiquity of the hand invites trouble and frequently finds it. Without being able to give specific figures, our experience shows the hand to be the most frequently involved. There are certain general characteristics which characterize the occupational dermatitis. In the first place, if the physician is familiar with the substance the employee is handling, he is in an advantageous position to determine the cause. This means an inspection of every phase of the work in which the patient is engaged, together with inquiry into his home conditions.

If health records are kept of employees for a period of years, it may be shown to be a seasonal occurrence of the dermatitis. For example, we have had three cases of sumac poisoning in which the patient is engaged, together with inquiry occupational disease. It was the regular occurrence of the disease, at the same time of the year which led to our suspicions.

If the rash disappears on cessation of the work, it is safe to say that the occupation is the provocative factor. It is well to inquire if the patient is better after the week-end. It was noticed in an ammunition industry that the workers on Monday morning appeared better than the preceding Friday. In other words, the dermatitis had practically cleared up. The fact that other employees suffer from the same condition at the same time is also of diagnostic aid. Most lesions are on

the back of the hand. It is well to examine for evidence of friction. Dr. Templeton⁷ says that wash women, by pressure of their nails on the wash board, in the presence of alkalis may produce onycholysis.

The conductor of an orchestra is proud of the lesion produced on his finger by his baton. The surgeon is not so proud of the lime and soda dermatitis resulting from attempts to sterilize his hands. The shoemaker who waxes his cord with his thumb probably will show the effects not only in the shape of the thumb, but the character of the epidermis. A close inspection of the hands may reveal the character of the work in which a person is engaged.

By far, the most numerous cases of dermatitis is our experience are due to the ordinary ringworm, or trichophyton. Efforts at prevention of this disease in industry should follow those adopted in public schools and gymnasiums, as suggested by Osborne. Two formaldehyde foot baths have been installed in our plant, with a lessening of the number of cases of ringworms of the hands and feet. The second in importance appears to be the ordinary garden variety of scabies. In practically every instance that we have discovered scabies, the employee has felt that it was due to some chemical which he was handling. One employee was vehement in claiming his finger lesions were due to his work, and was very much surprised to find how readily it yielded to sulphur ointment.

There are certain trades predisposing to dermatitis of the hands. Certainly, moisture favors ringworm. While it is clear that ringworm, per se, is not an occupational disease, it is frequently made so by assuming that a trauma of a particular type or of a constant type has assisted the entrance of the infection into the hand. It is hard to see how scabies could be interpreted as an occupational disease unless it could be proved that one employee contracted it from another which of course, in practice would be hard to do.

It is, of course, entirely impossible to mention all of the substances which may cause a dermatitis. The classification of Eller and Schwartz is fairly broad, but of course cannot possibly include all sub-

stances For example, certain kid gloves, woolen gloves, and in one particular instance, gloves of all kinds, cause a dermatitis The rotogravure section of the Sunday newspaper, toilet water and lotions, Flit, and of course, plants such as primrose, poison ivy, sumac, and many fruits and vegetables, such as lemons, oranges, tomatoes, have been known to cause a dermatitis to certain individuals

One employee developed a severe dermatitis of his forearm The only cause that could be determined was the fact that his suit was cleaned the previous day with carbon tetrachloride.

It is well to bear in mind that certain drugs may cause a dermatitis, although this is not so particularly true of dermatitis located on the hands as on the body

While we are aware that certain individuals may artificially produce an irritation of the skin, we have found no cases in our experience in which this was proven or even suspected

Two cases of dermatitis of the hands have arisen from treatment It is well-known, of course, that iodine and mercury in the same injury may set up a dermatitis It is not so generally known that mercuriolate and borated vaseline may do exactly the same thing It was our belief, in two instances, that a painful dermatitis developed from the incompatibility of these two drugs It will be noted that in one case, the remedy, borated vaseline, is a very simple one

As a typical illustration of a heavy metal poison which may be occasionally overlooked, we may sight the case of nickel A workman who was an expert at setting type, developed a rash on the backs of his hands, which existed for a long time and did not respond to treatment An examination of his work showed that a saw was used daily to cut through certain metals throwing out a dust of nickel and wood, which settled on the backs of his hands It was perfectly obvious that the man was suffering from a nickel dermatitis

The use of nickel has broadened a great deal, and if it can be proved that the workman is exposed to nickel dust, and it is found that he is suffering from a dermatitis of the hands, it is safe to say that it is the result of the nickel, other causes not being found It is well-known, of course, that the nickel of white gold in the form of wrist watches or

glasses frequently causes a dermatitis of the face or wrist There is, of course, no treatment other than the removal of the cause Some authors feel that psoriasis is in reality, nickel poisoning In this case, the nickel is found in the food

Various salts of chromic acid may also produce a severe dermatitis of the hands They penetrate deeply Where workmen are exposed to fumes of these salts, there should be an adequate exhaust ventilating system If there is not, irritation of the hands will certainly follow Ordinary photographic hypo is a good neutralizing agent in the treatment of burns and subsequent dermatitis The applications of chromium in industry are very diversified, and are much wider than is commonly supposed

Professor Hanzlik of the University of California, has described⁸ the pharmacology of the phenylenediamines They are used as the agents in the manufacture of dyes for furs and pelts, rubber industry, and the photographic industry The diamethyl and the diethyl phenylenediamines as pointed out by Professor Hanzlik, are very irritating to the skin, especially the former The disease usually attacks the hands, and may spread rapidly up the forearm, in exactly the same manner as does phenylhydrazine dermatitis The disease appears promptly on exposure to dust or solution Some individuals are so sensitive that a single exposure will produce a troublesome dermatitis If promptly removed, cure follows within three to fifteen days A very hot, weak solution of acetic acid sometimes gives relief to the intolerable itching Inasmuch as these substances are fat soluble, it is extremely difficult to reach them after they have penetrated the skin It may be occasionally necessary for this reason, to use a strong karyolytic agent to remove the deeply implanted chemical The phenylenediamines, of course, have been notorious in causing dermatitis, more particularly of the neck, when used in dyeing furs They are listed as illustrating how extremely susceptible some individuals may be to the action, while other individuals apparently seem to be immune

One employee suffered from a dermatitis of the hands and forearms which persisted for a long period of time Various remedies

were applied without success. Among other duties, this employee frequently passed from one dark room to another, and in doing so, it was necessary to pull aside a curtain which separated the two rooms. The curtains were dyed green. A patch test was suggested, and a strongly positive reaction showed that something in the curtain was the offending agent, probably the dye. The curtains were changed to another type.

Monomethyl-p-amino-phenol sulphate, known in the photographic field as elon, metol, etc., has had in the past, an unenviable reputation for producing dermatitis. It generally attacks the hands. There is an intense erythema and itching, which may spread up the forearm. Fissures and cracks may develop and of course, secondary infections. Erman, of England, has shown that purification of the elon entirely eliminates this irritating action which appears to be due to the phenyldiamines.

A chemist of very wide experience in handling the substance advises us that if the hands are washed frequently in a weak solution of acetic acid, that this prevents the development of the dermatitis. Washing with soap aggravates the condition.

In spite of our association in the manufacture of this product for a long period of time, we have seen no cases of dermatitis from this chemical, in spite of its bad reputation.

The extreme sensitivity of some individuals to various chemicals, places upon the industrial physician, the question of proper placement in industry. Certainly, the skin on the pre-employment examination is being given more consideration than formerly, and those who have had a bad record of dermatitis of one cause or another should not be placed where there is any hazard.

Experience has shown that extremely toxic substances may be handled with impunity if the proper safety measures are followed. The extent to which safety measures may be carried out, by the adoption of the improved mechanical methods, is one of the characteristics of this century. The recent development in the battery industry illustrates this point. A system of closed ventilation, wherein the fumes, spray or dust is kept within a closed space, is, of course, admirable, from every point of view, and in some instances offers the only hope of preven-

tion. It is surprising, in view of the development of modern safety equipment to find how many processes can be handled in this manner with safety, in which there was formerly a morbidity of the skin.

For some years, we have adopted the practice of clipping from the medical literature, all articles bearing upon the industrial dermatoses. These are pasted on loose leaves in a very large book, measuring nineteen by twenty inches. When a workman presents himself with a dermatitis, a list of all the substances which he uses is matched against a list compiled in our loose leaf book. If the substances used have a bad history, from literature at hand, and text-book description, the simplest way is to test them out on the individual to see if they actually produce a dermatitis in the particular patient at hand.

Unfortunately, most text-books, except those confined to the industrial dermatoses, mention altogether too little about skin reactions of various chemicals. As a matter of fact, the greatest list of offenders are not in the text books at all, and if they are to be found, must be taken from current chemical and medical literature.

In the matter of using protecting creams and lotions, we are of the opinion that they do not satisfy, and we are of the belief that engineering ingenuity can obviate their necessity. Some shop foremen have reported success in using certain of these creams in preventing folliculitis, due to oil. Our experience in their use has been very limited.

The author greatly appreciates the co-operation of his associates, Dr Wm A Sawyer, Medical Director of the Eastman Kodak Company, and Dr Charles Galaher, in the preparation of this paper.

The author has prepared an extensive bibliography on this subject and a copy will be gladly furnished to anyone requesting it.

Discussion

DR. G. M. LEWIS, *New York City*—Dr Slater is to be congratulated on his presentation of a very difficult subject. Hand dermatoses are, for the most part, of eczematous nature and their clinical and histologic characteristics are similar, if not identical, to eczemas and dermatitides in other locations. With industrial dermatoses, the same problems arise as with other eczemas of external origin. The exposed parts of the body are the sites of election, the hands being particularly favored. The covered portions of the body may become secondarily involved. Eczemas of the hands vary in appearance from the types showing a simple erythema with scaling to types exhibiting papules, vesicles, and bullae. Secondary lichenification, traumatization, and infection are common complications. Cure quickly follows (within a week or two) when the irritant or allergin causing the eruption ceases to come in contact with the patient's skin, it may be delayed in cases showing secondary infection.

The chief problem confronting the physician is to establish an accurate diagnosis. In a list of the more common hand dermatoses the following should be placed

- 1 Eczema (dermatitis venenata, endogenous, neurodermatitis, etc),
- 2 Dermatophytid,
- 3 Monilid,
- 4 Bacterid,
- 5 Infectious eczematoid dermatitis,
- 6 Drug eruptions,
- 7 Psoriasis and pustular psoriasis,
- 8 Scabies,
- 9 Dermatitis factitia,
- 10 Dysidrosis (pompholyx, cheilopompholyx)

Some of the rarer dermatoses are also occasionally noted on the hands.

The first step in diagnosis is a careful

history, paying particular attention to the family history regarding allergy, the patient's environment, habits, subjective symptoms (pain, itching, burning), number of attacks, activities during well periods as well as when the disease is present, manner of development of the eruption, the sequence of vents, the response to treatment (kinds)—all possible irritants. The clinical descriptions of the disease should include minute details as to its exact location, character of the disease, presence of complications, as well as possible foci of infections in the teeth, tonsils, sinus tracts, interdigital webs of the feet and the nails. Although the eruption may be confined to only a limited area of skin such as the hand, it is advisable that the patient be examined from head to feet for concomitant lesions.

Special examinations which may be useful in determining the diagnosis of hand dermatosis include the following:

- 1 Microscopic and cultural examination for fungi on hands and feet,
- 2 Skin tests with trichophytin, oidiomycin, and catarrhal vaccine,
- 3 Patch tests with suspected allergins as well as common substances not falling under direct suspicion,
- 4 White blood count,
- 5 An occlusive dressing over part of the eruption (if the eruption improves, the diagnosis of dermatitis venenata or dermatitis factitia may be suspected),
- 6 Histologic examination of the skin may prove requisite in certain instances.

In one hundred patients with eczematous hand lesions, the examination for fungi was positive in twenty-eight instances, sixteen infections being due to trichophyton, and twelve due to monilia. The skin tests tend to corroborate these findings. The white blood count was low except in cases showing pyogenic infection. Histologic examination was of distinct value in separating cases of dermatitis factitia, psoriasis, and pustular psoriasis from the eczemas.

INFECTIONS OF THE HAND

ROBERT F BARBER, M.D., *Brooklyn*

It still must be stated that the best way to treat a disease is to prevent it. More and more this is being done by industry, because it pays. Through the National Safety Council, industry has carefully and systematically considered the best ways in which to reduce accidents. This body is generously supported by contributions from individuals, companies, and corporations for the purpose of improving methods of safety and at the same time of stimulating their widespread usage. In

this way, industrial prophylaxis has reduced accidents and rendered unnecessary the surgeons' measures, which at best are not too good. At hand we have the annual report of The Brooklyn Union Gas Co. for the year 1935. This company employs 4,728 men.

Results of efforts towards the elimination of accidents have been most gratifying. In 1927 there were 754 accidents which resulted in loss of time from employment. In 1934 there were 84. In 1935 there were only 44.

that were serious enough to cause loss of time.

From this example alone one can see that for every accident today there were seventeen just eight years ago

One is often asked the most efficient method of first aid care in order to prevent infection. There is difference of opinion on this answer. Dr. Allen B. Kanavel strongly advocates the use of tincture of iodine, and he speaks with authority. This is the most common treatment, and possibly one of the best. Others equally strongly advocate some variety of the hypochlorites. No rule can be applied to this matter. The surgeon will know what is best in the individual case. All wounds must be rendered socially clean. If dirty ragged edges exist a debridement of the wound must be done. If a tendon is lacerated repair under rigid asepsis must be done at once. Immediate closure may be reasonable in some instances. In others it will be necessary to drain or to use the method of Carrel-Dakin. These considerations are of debatable relative importance. There is one point that all can agree upon. That is that all injuries be treated at once, either at the plant or at the hospital. If this be done there is the least opportunity for the starting of the growth of organisms in the wound. The treatment is instituted before the infection gets under way.

The commonest infectious agents are the staphylococcus and the streptococcus. While the one may produce a picture that often resembles the other, there are noted marked differences. The streptococcus is prone to give rise to diffusely spreading infections. Its limits are poorly defined, there is absent or delayed formation and circumscribing of pus. Ascending lymphangitis is often noted and bacteriemia is not infrequent.

On the other hand, the staphylococcus infections are more commonly well-circumscribed from the start. Pus is produced at once. It may burrow and spread far but it spreads in well-defined limits. Ascending lymphangitis and bacteriemia are less common. Obviously this type lends itself better to operative interference. Fortunately it is the most common.

Rarer infectious agents are the tubercle bacillus, giving rise to the anatomic tubercle or tenosynovitis, the yeasts and

moulds, and anthrax. Although we have seen several examples of each of these rarer infections, for our purposes here they have little more than academic interest.

It is not the intention to fatigue the mind with a long written account of structures concerned in the problem of infection, but it is proper to recall some outstanding features. The subcutaneous connective tissue of the hand varies greatly in thickness, toughness, and texture. The difference is most marked between the dense fat-filled finger pads and the thin movable skin on the dorsum of the hand. In the finger pads dense connective tissue bands extend to the periosteum. The anatomy alone accounts in a manner for the frequency with which a felon (the so-called anterior closed space infection of the finger) gives rise to bone invasion and destruction. On the dorsum of the finger we find the nail with its special structure accounting for the occurrence of paronychia, with rare involvement of the bone. In the midpalm under the deepest tendons is a potential fascial space, the deep palmar space. Here infection appears either arising locally or from extension upwards from a focus in any of the three middle fingers. The thenar space is a potential area for the accumulation of pus. It is located in the deep tissues at the base of the thumb. Here the pus will burrow towards the web of the thumb or the dorsum of the hand just above the web. This type of infection arises most often from the thumb. It may at times come from pus that breaks through from the base of the index finger. Infection in this space is frequent. A similar space occurs on the opposite side of the hand, the hypothenar space. It is smaller and lends itself readily to drainage. It is rarely the seat of infection.

The tendon sheaths are the most obvious routes for the spread of infection. From the finger we find the pus carried into the full extent of any given sheath. With the thumb and the little finger one may see at a glance with what ease extension may travel upwards. In the upper portion of the deep palm the ulna and radial bursae become invaded. Thus in turn carries the pus upwards still, under the annular ligament, and into the forearm. While such extensions are tragic

and threaten permanent disability if not immediate death for the patient, the majority of infections are limited to the fingers and the hand. The tendon sheaths even though filled with pus may be restored to full function following drainage. While this is not the rule at least it should be the goal of our efforts. Milder forms of tenosynovitis subside under conservative treatment, and do not give rise to impairment of tendon function.

Infection in the bones usually occurs by continuity of the inflammatory process. In its invasive march the pus reaches the periosteum through the adjacent areolar tissue. Invasion takes place and all degrees of destruction occur. In the earlier stages the progress of bone invasion is associated with great pain. Another almost constant finding is great local swelling. This is prone to persist until the sequestrum is removed. The joints become invaded by the same method as the bone. In addition they may be involved from invasion from previously infected bone. As a rule permanent changes are produced in the joint resulting in ultimate loss of function. Occasionally the bone will be invaded through the blood stream from some distant focus in a tooth or a tonsil or elsewhere. The course of this type of infection differs in no way from the course in the ordinary osteomyelitis by extension.

The lymphatics are very abundant on the palmar surface of the hand. The rich network of these vessels is a very important factor in the regional mechanism of defense, although the abundance of these vessels is doubtless more for physiological purposes than for anything else. On the dorsum of the hand the network of lymphatics is not so closely woven as on the palm. The lymphatics are on occasion disseminators of any infection. Their distribution both superficially and deep is so wide as to make the possibilities of spread legion, although that spread be at variance with the structural specifications of the anatomists as to fascial spaces, tendon sheaths or planes of extension. Here again, despite the fear of repetition, it may be noted that the streptococcus is prone to spread widely and rapidly by this route. In such types of infection operative procedures are both meddlesome and futile.

The blood vessels give rise to surgical interest because in extending infections the arteries are occasionally the seat of erosion from without. This gives rise to sudden hemorrhage. Packing of the wound or mass ligation on the spot may tide one over for the moment, but this does not suffice. A better and safer course is to ligate the vessel through healthy tissue above the infected area. Kanavel states that the ulna artery is the chief offender in his experience and quotes two cases. My experience has been identical except that it was the radial artery. The veins often become the seat of infection from without and thrombophlebitis follows. This rarely extends. Venous complications seem to have little surgical importance.

Treatment cannot be arbitrarily outlined. If such were done and followed the next patient would probably prove to be an exception and the treatment ill-advised. For this reason it seems best to suggest that in the early stages of an infection there is a preoperative period when the pathological destiny is obscure and the surgical procedures are not obvious. At this stage the first requisite is rest to the part. The second is continuous moist heat by means of abundant dressings moistened with saline and enclosing a hot water bottle. In general the greatest swelling is on the dorsum of the hand but the incisions are made on the palmar surface.

When should one proceed to incise and drain? A persistent point of tenderness in an indurated area means pus in the fascial space beneath. A line of tenderness over a tendon sheath with great pain on attempted flexion of the finger means pus in the sheath. One should proceed to operate with nothing more obvious than this. The drainage may be the one thing that will limit the spread of the infection. The lines of incision are shown well in the cuts from Kanavel's "Infections of the Hand" (In the presentation, the author showed lantern slides—*Editor*). We follow these lines except for the thenar space infections where we prefer a curved incision around the base of the thumb, opening the thenar space and the long flexor sheath if necessary, and then extending the incision through the web to the dorsum of the hand. In our experi-

ence this incision has seemed to give a good ultimate function for the thumb. The x-ray is used routinely for bone detail. The probe is of great help in picking up bone without periosteum at the bottom of a sinus tract. An anesthetic is given as a matter of necessity in the average case because the pain of operative procedures is unbearable. Nitrous oxide is our choice, but any light anesthetic suffices.

The use of drains is advisable because the tough tissues of the hand tend to fall together after incision. In order that a drain may not act as a stopper of the opening, it is best to use rubber tissue or rubber tubing. There is no objection to the use of vaseline gauze. All during this stage of treatment moist heat is continued. After a few days it is better to change to dry heat through the agency of a lamp. Bier's hyperemic treatment is not used by us. We were never convinced of its value either in practice or theory. One might call the process of inflammation and repair a miracle. We use learned technical expressions to record what goes on, but how little is known of why it goes on. To interfere with the rapidity with which blood moves in and out of a given area which is the seat of a vital conflict may be anything but beneficial. Simple surgical procedures are used in the final stages of healing.

Physical therapy is a most important aid in the restoration to usefulness of the infected hand. It should be employed in every case where there is limitation of function. To neglect to use this form of therapy might well be regarded as a mild form of malpractice. The use of anesthesia to break adhesions and increase range of motion will occasionally be found necessary.

The advantages of the proper surgical handling of infections of the hand are best seen in the results, both functional and cosmetic. The scars of surgical intervention fade with time almost without distortion of the soft parts. The scars are not at pressure points and therefore are not painful. The lines of incision are not through important anatomical structures and the result is the best working hand obtainable. When there is loss of digits, that loss becomes both an individual and an industrial tragedy. In this state the loss for a working man is scheduled by weeks wages.

	<i>Weeks</i>
For loss of thumb or its use	75
First or index finger	46
Second finger	30
Third finger	25
Fourth or little finger	15
Entire hand	244

How meager this is to compensate for the resultant loss of income for a lifetime. There may be no occupation, or at best an unattractive type of employment at much lower wage scale.

Summary

1 Industrial and medical prophylaxis is the best treatment for the infections of the hand.

2 The form that the inflammation takes is often determined by the types of bacteria causing the infection.

3 Gross anatomical knowledge is fundamentally essential for proper treatment.

4 Surgical therapy should be definite and accurate, and should include physical therapy.

5 The state and the individual pay for the bad end results, but mostly the individual.

1257 DEAN ST

Discussion

DR. P. A. WADE, *New York City*—Dr Barber is to be congratulated upon his very interesting and instructive paper. I have little to add to what he has already said.

However, there are some points I would like to emphasize. *First*, infections of the hand, except for the most minor procedures, should be done in an operating room with adequate assistance and with general anesthesia. Although hand infections have of late years been elevated to their proper position in the field of surgery, I believe

there are still too many incisions made in clinics and offices. One fault, perhaps is the attitude of the patient who often considers infections of the hand and fingers as unimportant conditions. It is our duty to educate the public so that we will not meet the resistance of the patient in insisting upon admission to the hospital and proper operation.

Second, tendon sheath infections should be operated upon under general anesthesia with the use of a tourniquet, preferably an

Esmarch bandage, so that proper anatomical dissection may be carried out to insure proper drainage with the least possible amount of trauma to involved tissues

Third, local anesthesia in operations on the fingers should be used with great caution, and I believe that the practice of using, as a local anesthesia, the usual preparation of novocain with adrenalin is distinctly harmful and should never be used in digital nerve block anesthesia on fingers. Garlock reported four cases of gangrene of the finger following digital nerve block anesthesia. In all of these cases a rubber band tourniquet was used in conjunction with novocain. He did not report whether or not adrenalin was used in conjunction with the novocain. Nowadays, the drug companies make a practice of dispensing novocain with adrenalin unless the doctor insists upon novocain without adrenalin. In all probability the novocain in these cases contained adrenalin. I have recently seen

a case of gangrene of the finger following a minor procedure in which novocain with adrenalin was used as a local anesthesia. In this case no tourniquet was used, and it was undoubtedly the anesthetic solution which caused the circulatory disturbance. Undoubtedly most cases may be anesthetized with this solution without adverse results, but in the rare case there may be some susceptibility to the novocain, and especially in fingers in which the circulation has already been damaged by infection. It is more preferable to use a general anesthesia than to subject the tissues of the finger to further damage by the local anesthesia.

Fourth, I would like to emphasize one more point. A most important part in the treatment of hand infections is the post-operative care. Wet dressings, hand soaks, and the changing of dressings should be done in the strictest aseptic technic, for some of the difficulties arising in hand infections arise from secondary infections.

MANAGEMENT OF INJURIES OF THE TENDONS AND NERVES OF THE HAND

JOHN H GARLOCK, M D, F A C S, *New York City*

Many injuries of the hand which lacerate the skin involve the tendons also. Every laceration or incised wound of the hand calls for a careful examination of active flexion and extension of all the finger joints. It is certain that, if this were done consistently and operation for the repair of a divided tendon were performed as an emergency soon after the receipt of the injury, there would be fewer hand disabilities in a class of patients who depend upon proper hand function for a livelihood.

It is to be remembered that the flexor tendons possess a most delicate and unusually efficient gliding mechanism, the surrounding tendon sheath, and the vaginal ligaments over the front of the proximal and middle phalanges and the heads of the metacarpal bones. The slightest injury to the endothelial lining of the tendons and sheaths produces a marked reaction. Adhesions form quickly and bind tendon to sheath. The intensity of this reaction is directly dependent upon the extent of the trauma. Therefore, in all operative work upon these delicate tissues, the technic must be as ideally atraumatic as possible. One must think in terms of microscopic injury. This attitude to-

ward surgery of the flexor tendons may very well be applied to other problems in hand surgery. It is an ideal for which every surgeon who attempts repair of tendons or reconstruction work in the hand must strive.

In the first place, every possibility for tremor must be eliminated. The patient's hand should be fixed to the operating table in such a way as to prevent the slightest movement. The surgeon himself should be comfortably seated with his forearms braced against the table over which he is working. Asepsis in the operating room and amongst the nurses and assistants must be of the most rigid sort. To diminish the trauma incident to the operation itself, a bloodless field is indicated. This can be obtained by the proper application of an Esmarch bandage, which is of inestimable value in hand surgery. If correctly applied, one need have little fear of untoward sequelae, such as nerve palsies. The hand and forearm are first wrapped in a single layer of sterile towel. The extremity is then held elevated for a few minutes. The sterilized Esmarch bandage is started at the finger tips and rolled down the forearm, each turn being pulled as tightly as the rubber

will permit, and overlapping the turn of the bandage that preceded it. In working on the hand, one need go no further with the bandage than the upper third of the forearm. At the point where it terminates, the towelling should be of four or five thicknesses to avoid the direct pressure of the bandage on the skin. Should it be found necessary to extend the bandage to the upper arm, it is wise to have the underlying towel of six or eight thicknesses. The latter precaution is taken to avoid injury of the musculospiral nerve which lies nearer the skin here than do the nerves in the upper part of the forearm. The Esmarch bandage may either be left in this position until the close of the operation, or a blood pressure cuff may be applied to the arm above the

termination of the Esmarch which may be removed after the blood pressure apparatus has been pumped up until it registers about two hundred and fifty mm of mercury.

The surgeon should try to complete the operation within the period of one to one and a half hours. If he feels that the operation will be a long one, the additional use of the blood pressure cuff is indicated. During the course of a prolonged operation, the pressure in the apparatus may be diminished for a few seconds and then raised to its previous reading. This may be done every fifteen

Fig 1 Drawing of hand to indicate the most common sites of wounds in the fingers and palm, resulting in injury to the flexor tendons, an operative approach in each instance. The transverse incision in the distal flexion creases is sometimes used to obtain complete exposure. This, however, is infrequently necessary. The original wound in the skin and subcutaneous tissues must be completely debrided before closure. Digital incisions must avoid the anterior surface of the finger and not cross flexion creases at right angles. Great care is to be exerted to maintain the integrity of the vaginal ligaments of the tendon sheaths.

Fig 2 (a, b, c, d, e, and f) Method used for repair of divided tendons. At A, the suture material is passed transversely through the tendon about $\frac{1}{2}$ inch from its extremity. Both ends of suture which consists of fine silk, are threaded on fine straight needles. One of the needles is made to pass obliquely through tendon, coming out on opposite side. The other needle is passed through in a similar manner, coming out at side opposite point of exit of first needle. B This leaves a minimum of suture material on surface of tendon. The needles are then passed again obliquely through tendon and made to come out at opposite sides, as shown at C. Needles are then passed again through tendon and emerge at tendon-end near periphery, as shown in D. It will be noted that a minimum amount of suture material lies exposed on surface of tendon. The same procedure is carried out in the other end of the divided tendon. When knots are tied uniting the proximal and distal extremities of tendon, it will be seen that they lie buried between the tendon ends, E. They should be tied as to cause "buckling" of tendon at site of repair, F. Before knots are tied, the slack of suture in tendons must be "taken up" by pulling on ends of suture. Before the needles are made to emerge at end of tendon, a fresh accurate transverse extremity is produced by excising with a razor blade the end which has been held in an Allis clamp. Thus all traumatized tissue is excised before repair is completed.

Esmarch bandage, so that proper anatomical dissection may be carried out to insure proper drainage with the least possible amount of trauma to involved tissues.

Third, local anesthesia in operations on the fingers should be used with great caution, and I believe that the practice of using, as a local anesthesia, the usual preparation of novocain with adrenalin is distinctly harmful and should never be used in digital nerve block anesthesia on fingers. Garlock reported four cases of gangrene of the finger following digital nerve block anesthesia. In all of these cases a rubber band tourniquet was used in conjunction with novocain. He did not report whether or not adrenalin was used in conjunction with the novocain. Nowadays, the drug companies make a practice of dispensing novocain with adrenalin unless the doctor insists upon novocain without adrenalin. In all probability the novocain in these cases contained adrenalin. I have recently seen

a case of gangrene of the finger following a minor procedure in which novocain with adrenalin was used as a local anesthesia. In this case no tourniquet was used, and it was undoubtedly the anesthetic solution which caused the circulatory disturbance. Undoubtedly most cases may be anesthetized with this solution without adverse results, but in the rare case there may be some susceptibility to the novocain, and especially in fingers in which the circulation has already been damaged by infection. It is more preferable to use a general anesthesia than to subject the tissues of the finger to further damage by the local anesthesia.

Fourth, I would like to emphasize one more point. A most important part in the treatment of hand infections is the post-operative care. Wet dressings, hand soaks, and the changing of dressings should be done in the strictest aseptic technic, for some of the difficulties arising in hand infections arise from secondary infections.

MANAGEMENT OF INJURIES OF THE TENDONS AND NERVES OF THE HAND

JOHN H. GARLOCK, M.D., F.A.C.S., *New York City*

Many injuries of the hand which lacerate the skin involve the tendons also. Every laceration or incised wound of the hand calls for a careful examination of active flexion and extension of all the finger joints. It is certain that, if this were done consistently and operation for the repair of a divided tendon were performed as an emergency soon after the receipt of the injury, there would be fewer hand disabilities in a class of patients who depend upon proper hand function for a livelihood.

It is to be remembered that the flexor tendons possess a most delicate and unusually efficient gliding mechanism, the surrounding tendon sheath, and the vaginal ligaments over the front of the proximal and middle phalanges and the heads of the metacarpal bones. The slightest injury to the endothelial lining of the tendons and sheaths produces a marked reaction. Adhesions form quickly and bind tendon to sheath. The intensity of this reaction is directly dependent upon the extent of the trauma. Therefore, in all operative work upon these delicate tissues, the technic must be as ideally atraumatic as possible. One must think in terms of microscopic injury. This attitude to-

ward surgery of the flexor tendons may very well be applied to other problems in hand surgery. It is an ideal for which every surgeon who attempts repair of tendons or reconstruction work in the hand must strive.

In the first place, every possibility for tremor must be eliminated. The patient's hand should be fixed to the operating table in such a way as to prevent the slightest movement. The surgeon himself should be comfortably seated with his forearms braced against the table over which he is working. Asepsis in the operating room and amongst the nurses and assistants must be of the most rigid sort. To diminish the trauma incident to the operation itself, a bloodless field is indicated. This can be obtained by the proper application of an Esmarch bandage, which is of inestimable value in hand surgery. If correctly applied, one need have little fear of untoward sequelae, such as nerve palsies. The hand and forearm are first wrapped in a single layer of sterile towel. The extremity is then held elevated for a few minutes. The sterilized Esmarch bandage is started at the finger tips and rolled down the forearm, each turn being pulled as tightly as the rubber

ing debris and soap-suds into the wound. Following drying of the parts with sterile towels, the skin is washed off with benzine followed by ether. The extremity up to the elbow is then painted with three and a half per cent iodine, care being exerted to prevent the entrance of any iodine into the tendon sheath. I wish to emphasize the importance of this method of skin sterilization, which, in my opinion, is the correct one because I recently heard a surgeon, in reporting the end-results of a large series of hand injuries, make the statement that the tendon sheath should be liberally doused with tincture of iodine. He felt that because of this procedure alone, no infections had developed. Yet in spite of this, the end-results in a large proportion of the cases were hardly what one would strive for. It is a well-known fact that iodine, when applied to endothelial-lined surfaces, produces a violent

reaction. This is especially noteworthy in flexor tendon sheaths.

When the wound is found before operation to be ragged and dirty, obviously grossly contaminated, and the surrounding skin is covered with grime and dried blood, and there has been considerable crushing of the tissues, in addition to laceration, I feel that the repair of the tendon should be deferred until the wound has healed, the immediate interference consisting solely in a general cleansing and debridement. Two or three weeks later, one may safely undertake the repair of the tendon in a clean field. In the presence of other wounds within the initial six hours following the injury, immediate tenorrhaphy can be done with safety after the skin cleansing already described.

The site of incision for exposure of the ends of the divided tendon or tendons will depend upon the situation of the original wound. It is important to remember that the incision should always be

Fig 5 (a and b) Illustrating two problems in hand surgery. Patient received a lacerated wound over proximal digital flexion crease, caused by a buzz-saw. Finger was almost amputated. At operation both flexor tendons were found divided as were also both digital nerves of index finger. Proximal phalanx was cut almost in two. Operation consisted in thorough debridement and repair of all divided structures including digital nerves. This operation was performed in 1923. Photographs at end of two years indicate return of complete function. There is no interference of sensation in the finger, indicating regeneration of digital nerves.

Fig 6 (a and b) Laceration across lower forearm produced by broken automobile windshield. All structures in the anterior compartment of forearm were divided. Debridement and primary suture performed within two hours of accident. Active motion was started on sixth postoperative day. A posterior metal splint maintained wrist in partial flexion for twenty-two days. Wound healed by primary union. Photographs were taken at the end of one year and indicate return of complete function.

Fig 3 (a and b) Illustrating division of flexor profundus tendon of right middle finger cm proximal to its insertion. Because of extensive skin soiling, operation was deferred until thirteen days after injury, when wound was completely healed. The technic as described in text was followed. Active motion was instituted on seventh postoperative day. Photographs indicate result at end of one year.

Fig 4. (a and b) Division of both flexor tendons of left middle finger in palm at region of outer end of distal palmar flexion crease. Operation was performed six weeks after injury. It will be noted that incision is placed to one side of anatomical location of the tendons. Active motion was instituted on eighth postoperative day. Photographs were taken at end of one year.

or twenty minutes. For an ordinary primary tenorrhaphy, this is rarely indicated because the operation usually consumes less than an hour. I have never seen a musculospiral paralysis following the use of an Esmarch bandage as described.

In the performance of the operation, all tissues must be handled with as great gentleness and delicacy as possible. One must always maintain a wholesome respect for tissues and keep one's mind on their postoperative reaction. This is applicable to skin as well as subcutaneous tissues, muscles, tendons, and nerves. Instruments should be the sharpest obtainable and small in size. The surgeon must avoid heavy catgut, large knots, dead spaces, tension of sutures, mass ligation, too many stitches, foreign bodies in fat, closure with incomplete hemostasis, the use of very hot sponges, and drying of the tissues due to prolonged exposure. In

ligating bleeding points, the finest catgut should be used. The reduction of the time of operation to a minimum may be obtained by good teamwork, conservation of movements, the elimination of unnecessary puttering, and an adequate exposure of the field of operation. The foregoing is a prime requisite if one is to expect satisfactory results in the surgery of the tendons and nerves of the hand.

Flexor tendons. After the diagnosis of a divided flexor tendon is made, operation for its repair should soon follow. In the vast majority of cases this may safely be done provided that, at operation, the original wound is thoroughly debrided. A general anesthetic should always be administered. The skin of the hand and forearm must be carefully prepared before repair is attempted. This entails first a careful scrubbing with sterile soap and brush, followed by irrigation with saline. Care should be exerted to prevent wash-

tendon In addition, it permits early active motion The most efficient suture material for this purpose is Turner's patent ligature silk of about number three or four size Very fine straight needles are used Before the emergence of the silk at the end of the tendon which has been held grasped by an Allis clamp, the contused part held by the clamp is excised with a sharp razor blade so as to give a fresh transverse nontraumatized end When the corresponding ends of the silk in the two tendons are tied, it will be seen that the knots lie between the tendon ends, and that there is accurate apposition This method of suture accomplishes two things It produces a firm mechanical joining of the tendon ends and leaves the smallest amount of suture material on the surface of the tendons, thus reducing to a minimum the possibility of adhesions Following the repair of the tendon, the small wounds in the tendon sheath should be closed with interrupted sutures of fine catgut. The Esmarch bandage is then removed and all bleeding points carefully ligated The wound must be thoroughly dry before the skin is closed with interrupted sutures of fine chromic catgut.

Following the application of dressings, it has been my custom to apply a light plaster glove with the repaired finger and wrist in moderate flexion From the experimental work already alluded to, it was found that active motion can safely be started on about the fifth or sixth postoperative day Following this initial five day period, the splint is removed daily and the patient is encouraged to actively flex and extend the finger *within the limits of pain* On about the ninth or tenth day, the plaster glove may be discarded, and a dorsal metal splint applied so as to keep the wrist in flexion Finger immobilization after this date seems unnecessary because, by holding the wrist in flexion, one diminishes the intensity of contraction of the flexor muscles This dorsal splint should be worn for a period of about twenty-one to twenty-five days Our experimental work indicates that union of a repaired tendon is firm enough at this date to warrant discarding the splint. After this period, many other remedies may be utilized, such as frequent strong galvanic stimulation of the muscles to produce contraction, thus help-

ing to break adhesions, properly administered baking and massage, hot soaks, whirlpool baths, re-education exercises, etc.

While I do not question the value of these procedures and constantly utilize them, I feel that more can be accomplished by carefully controlled and personally encouraged daily active motion in the initial six or eight weeks of treatment The time element must also be considered as having a direct bearing on the eventual outcome inasmuch as an optimum result may not be obtained until a period of four to six or more months has elapsed

A not uncommon injury is a laceration across the front of the wrist with division of most or all of the structures in this situation Such an injury calls for a careful examination of the function of the small muscles of the hand, and skin sensation of the extremity distal to the point of trauma in order to determine the presence or absence of injury to either the median or ulnar nerves or both Not infrequently, it will be found that both these structures as well as all the flexor tendons have been divided by the trauma I have seen a number of cases with injuries in this situation produced by a sharp-pointed object resulting in isolated injury of either the median or ulnar nerves without involvement of the tendons It is surprising that so many lacerations in this situation are treated by suture of the skin alone without any attempt to determine the presence or absence of tendon or nerve injury

The treatment of such an injury calls for immediate operation by a competent surgeon. A thorough knowledge of the anatomy of the structures in this region is necessary for the performance of an intelligent operation which is bound to be a tedious one Following the preparation of the skin, and the application of an Esmarch bandage as already described, the wound is completely debrided. A longitudinal incision proximal and distal to the original wound will be found necessary to locate the retracted ends of the divided structures Repair of the tendons which must be accurately fitted together follows the same technic as already described A divided median or ulnar nerve may be repaired by the insertion of five or six sutures of fine silk placed only

made on the lateral aspect of the finger. Making a median longitudinal incision is a pernicious practice because the subsequent healing is bound to produce a flexion contracture. In the palm, the incision is placed lateral to the anatomical position of the tendon to be repaired. If the flexor profundus tendon has been divided at about the center of the middle phalanx, its proximal end will retract to about the region of the proximal digital flexion crease, being prevented from retracting further by the vincula tendineae

this is done, the chances for development of a flexion contracture are greatly enhanced. Very often, because of the attachment of the vincula tendineae, it will be found that the proximal ends of the divided tendons are very close to the original wound. Should it be found that they have retracted, a separate transverse incision may be made in the palm. Every effort should be made to preserve the integrity of the vincula tendineae because it is through these structures that the tendons derive most of their blood supply.

Fig 7 (a, b, c, and d) Case illustrating the early return of finger mobility after division of all the structures at the front of wrist. A complete debridement and repair was performed two hours after injury. There has been a complete regeneration of both ulnar and median nerves, as indicated in the photographs. Normal fullness of palm, abduction, and adduction of the fingers in the extended position, and opposition of the thumb, should be particularly noted.

Instead of extending the lateral incision down to this point, a transverse incision may be made in this crease, and through a small transverse opening in the tendon sheath, the retracted end may be isolated and threaded through the remainder of the sheath up to the site of division of the tendon after the suture has been inserted. By this maneuver, one diminishes the operative trauma and also preserves the vaginal ligaments of the tendon sheath. If the original wound is located over the front of the proximal phalanx, one or both of the flexor tendons may be divided. The lateral incision is here also used, but its proximal end should not extend beyond the proximal digital flexion crease, because it has been found that, if

When the original wound is located over the proximal phalanx of the thumb, it will be found that the proximal end of the flexor longus pollicis tendon is retracted very often to a point opposite the wrist joint. A separate side incision is necessary here for the exposure of this part of the tendon which may then be threaded through the sheath after the silk suture has been placed in its end, and joined to the distal end of the tendon.

In the actual repair of a divided tendon, I am thoroughly convinced that silk should be used. Experimental work which was undertaken along these lines some years ago, indicated that silk causes the least reaction and remains as an innocuous foreign body in the substance of the

motor branch of the ulnar. The remaining branches of these two nerves are sensory in function, but are just as important.

To determine the presence or absence of nerve injury, it is imperative that skin sensation distal to the injury be tested in every instance. This applies just as much to finger injuries with severance of the digital nerves as to wounds in the palm and at the wrist where the main nerves may be involved. Once loss of skin sensation is evident on physical examination, the repair of the divided nerve is indicated. This should be done at the same time that the laceration or divided tendon is repaired.

The surgical repair of nerves in the hand is not a particularly difficult operation. The results in my experience have been fairly uniformly satisfactory. The unsatisfactory end-results that I have seen have been in cases of injury of the ulnar nerve at or above the wrist. The reasons for this are not clear, but it appears that other surgeons have had the same experience. The end-results following suture of divided digital nerves have been unusually brilliant. This is probably due to the fact that these nerves are purely sensory and do not contain mixed fibers. Bunnell, of San Francisco, in an excellent article, was the first to report a series of such cases with practically uniformly successful results. Observation of such cases indicates that the period of regeneration is shorter, the nearer one approaches the tip of the finger, and is longer in cases where the injury is more proximally located. The average period of regeneration of a divided median or ulnar nerve at the wrist is about thirteen or fourteen months. Where a digital nerve has been divided at about the middle phalanx, the average period for regeneration is about one and a half months.

In the actual repair of a divided nerve, the same atraumatic technic already described should be followed. To approximate the divided ends, the finest silk should be used. I have made use of the fine needles and silk sold on the market for suturing blood vessels. Five or six sutures are placed in the perineural tissues in such a way that, when the knots are tied there will be an accurate approximation of the ends of the divided nerves.

Under no circumstances should the suture material enter the substance of the nerve. To permit repair, the involved parts should be put in a position of relaxation with flexion of the various joints. Depending upon which nerve has been repaired, this position of flexion should be maintained for a period of three to five weeks. Electrical stimulation of the muscles supplied by the divided nerve is an important factor in postoperative therapy.

Lacerations. I wish to emphasize the subject of lacerations of the hand solely to warn against the common practice of indiscriminate suturing. This applies especially to wounds on the flexor surface. If, however, the laceration receives the treatment already referred to—careful skin preparation and wound debridement soon after receipt of the injury—the situation is then different, and the wound may be safely sutured. This, however, usually requires an anesthetic and may not always be feasible. In the absence of such preliminary treatment, it is safer to be content with as thorough a cleansing as is possible under the circumstances, proper iodization of the wound and surround-

Fig 9 (a and b) Final result of case shown in Fig 8. Scars over anterior aspects of the middle and ring fingers were excised and defects covered with full thickness skin grafts taken from anterior aspect of the same forearm. The grafts "took" completely and the photographs indicate result six months later.

Fig 8 (a and b) This illustrates proper treatment for lacerated wound over front of fingers exposing flexor tendons. This patient's hand was caught in a dough mixing machine. The trauma was of the tearing and compressing type. Extensive irregularly-shaped lacerated wounds were found over front of index, middle, and ring fingers, exposing flexor tendons. After careful skin preparation, wounds were completely debrided and sutured so as to cover exposed tendons and, at the same time, avoiding undue tension. Active motion was instituted immediately. The photographs were taken on sixth postoperative day, and indicate the amount of active flexion on that date.

in the perineural tissues and without disturbing the natural position of the two segments of the nerve by rotation of either one. On more than one occasion, I have seen the proximal end of a divided nerve sutured to the distal end of a tendon or vice versa. Following complete hemostasis, the wound may be sutured without drainage. Postoperative treatment consists in placing the wrist and fingers in flexion and instituting active motion on about the fifth or sixth postoperative day. Flexion of the wrist should be maintained for a period of about three or four weeks. As soon as possible, galvanic and faradic stimulation of the muscles supplied by the divided nerve should be resorted to, in order to lessen the atrophy that takes place. Complete regeneration of a divided nerve in this situation after the operative technic as described may not be evident before the expiration of twelve to twenty-four months.

Extensor tendons Injuries on the dorsum of the hand and fingers that involve division of the extensor tendons offer a much better prognosis as to return of function than those on the flexor aspect because of the absence of tendon sheaths over the major portion of this aspect of the hand. The diagnosis is simple and the treatment evident. When, at operation, the fascia extending between the various tendons is found divided, repair of this structure should also be undertaken because of the added strength it gives the suture line in the tendon itself. A wound situated in the region of the posterior annular ligament divides the extensor tendon at the location of its tendon sheath. However, should adhesions form between the extensor tendon and its sheath at this point, the limitation of function will not be proportionately as great as when adhesions form between the flexor tendons and their sheaths. In my experience, the surgery of extensor tendons following injuries has given practically uniformly good results.

Nerves of the Hand

Proper hand function is dependent upon adequate sensation and finger mobility. Complete sensation is directly concerned with nerve integrity and motion is dependent upon both muscle and tendon function as well as complete nerve distribution. The one is as important as the other. The degree of disability that a divided nerve entails depends upon which nerve is involved and at what level the point of division has occurred. Thus, severance of the median nerve at or above the wrist produces anesthesia in the three digits most often used. In addition to skin anesthesia, joint sense is disturbed. Trophic changes appear and the patient often burns the involved fingers without knowing it. There is also a loss of power of opposition of the thumb to the fingers. Severance of the ulnar nerve at or above the wrist produces anesthesia in the area supplied by this nerve and results in a claw-hand, with deficient thumb function and loss of the fine movements of the fingers. From the standpoint of hand function, then, it will be seen that the two most important nerves in the hand proper are the thenar motor branch of the median, and the

FRACTURES OF THE BONES OF THE HAND

CLAY RAY MURRAY, M D, F A C S, *New York City**Associate Professor of Surgery, College of Physicians and Surgeons, Columbia University,**Associate Attending Surgeon, Presbyterian Hospital*

It is a matter of importance to realize that in industrial surgery today the disability time is frequently as important as the end result obtained. Fractures of the bones of the hands are among the most disabling of industrial injuries both as regards the temporary disability time and the residual permanent disability award. The reason for this lies in the delicate mechanism involved in movements of the hands and fingers and the correspondingly delicate soft part anatomy making it possible. The existence of the fracture frequently blinds us to the fact that the common causes of disability are not bony deformity and nonunion, but disturbance of the nicely and finely adjusted mechanism of tendon, joint capsule, and joint synovial pouches which normally make possible the beautiful mechanical efficiency of the hand.

Before discussing these disabling soft part changes secondary to fracture in the hand, let us briefly review the anatomy and mechanism of joint and tendon action. The tendons on the front of the hand are supplied with sheaths. Those on the back of the hand are not. In either instance, they do not lie loose in a cavity through which they slide. The tendon in its sheath is joined to the latter by a continuous broad mesotenon of areolar tissue which serves to transmit nutrition. The tendon unprotected by a sheath is joined to the underlying and surrounding tissues by a similar areolar tissue paratenon serving the same purpose. In order that tendons may move back and forth freely, as they must for adequate use of the hand and fingers, areolar tissue connections of the tendon must remain loose, delicate, elastic, and flexible. Infiltrate them with hemorrhage, or the exudation which accompanies the inflammatory reaction of injury, and allow that infiltration to become organized and you have

thickened, gross, inelastic and relatively inflexible connection of tendon to surrounding structure, relative fixation or limitation of range of tendon motion, and stiff fingers, even though bone and joint be normal. This limitation is temporary when due to infiltration by hemorrhage and exudate. It becomes permanent when hemorrhage and exudate become organized into tissue unless the thickened and inelastic new tissue can be stretched and rendered elastic—often a long slow process and often an impossibility. Even without pathology in the meso- or paratenon, if the tendon is kept immobilized the same loss of elasticity and contracture of these areolar bands occurs as in the joint capsule of an immobilized joint, with the same resultant loss of flexibility which has to be restored by stretching and exercise. Here then is, in contemplation of this anatomy and this pathology, our first indication for principles of therapy in hand fractures—get rid of hemorrhage and exudation about tendons and tendon sheaths before it organizes, and keep the tendons from fixation in one position for any considerable period of time—and this doesn't mean months—it means weeks or even days in many instances.

The second of the mechanisms, disturbance of which entails serious functional loss, is that of the joints of the fingers (Fig 1). Study of the diagram with its explanatory note will give an idea of the beauty of the mechanics involved. Obliterate the synovial pouches even partially, thicken the delicate and thin capsule merely a little, pucker or distort the glenoid ligament merely a bit, and you have limited motion and stiffness, even though the tendon mechanism be normal. Where the joint capsule is actually adjacent to or involved in the fracture line the normal healing process *in itself* may produce sufficient

ing skin, and the application of one or two strips of sterile adhesive so placed as to approximate the wound edges. In the fingers, these strips should never be applied to completely encircle a digit.

Any extensive laceration calls for an immediate operation consisting of a thorough cleansing and a complete debridement. Very frequently, one sees lacerated wounds over the front of the fingers which have been produced by a crushing force. They are usually irregularly-shaped and often extend down to the tendon sheath, exposing the flexor tendons. The great danger in these cases is

the development of a tendon sheath infection. It is felt that the incidence of this complication may be reduced to a minimum by careful cleansing of the wound and surrounding skin and a painstaking excision of the edges of the laceration. As many sutures should be inserted as are necessary to cover over the exposed tendons. Their number should be the minimum in order to avoid undue tension. I believe that tension of tissues is a great factor in the development of infections following the operation of debridement and suture for compound injuries.

Discussion

DR. MATHER CLEVELAND, *New York City*—I congratulate Dr. Garlock on his terse, lucid presentation of facts of tendon repair in the hand and fingers. I can find nothing to disagree with and merely wish to emphasize certain of his points.

To do nice tendon repair a bloodless field is absolutely necessary, and I have found a blood pressure cuff offers the best means of securing this hemostasis. If the operation is lengthy, I release the tourniquet at thirty-five-forty minute intervals.

The preparation of the skin is of great importance, and I have felt that the patient's hand should be as thoroughly scrubbed, under anesthesia if necessary, as if he were going to perform the operation. Dr. Garlock has emphasized the importance of proper skin incisions which do not cross digital flexion creases in the midline.

The use of silk for suture material is important because it has been found by microscopic section to cause less trauma to tissues and by its tensile strength it allows early active motion which is essential for the return of function.

My experience coincides with that of Dr. Garlock in that the regeneration of the motor branches of the ulnar nerve when it is severed proximal to the volar carpal ligament is very problematical.

In my series of cases, seventy-two per cent of the incised wounds of the hand and fingers, involving tendons, are on the flexor surface, while twenty-eight per cent are on the dorsal surface. This is because the hand, in use or in defense, is extended with the palm and flexor surface presented toward the machine, knife, broken glass, etc. in most instances. This also holds true for the penetrating injuries which cause infections of the fingers, tendon sheaths, and palmar spaces.

Good results in hand and finger tendon

surgery are only obtained by meticulous attention to detail. Dr. Garlock may have made it sound too easy. I have been able to get perfect results from anatomic, functional, and economic standpoints in a little over fifty-five per cent of the patients upon whom I have operated, thirty-six per cent had a useful range of motion and a hand which did not incapacitate them. The remaining two cases, or nine per cent, were failures, one from infection and the other from failure of the motor branch of the ulnar nerve to regenerate even after a second suture was performed.

The healing in my rather small series was clean in sixty per cent, while forty per cent showed some evidence of infection. This infection was of minor significance for the most part, as four of the cases rated as infected had perfect end-results. I realize that danger of infection has caused some surgeons to advocate deferring tendon repair until the wounds have healed. The difficulties of secondary suture are so great that I feel that after a careful cleaning of the hand primary repair should be done.

The time elapsing between the injury and the tendon repair is important. The longer this interval is, the greater is the opportunity for retraction of tendon ends and for infection. In this series the repair followed the injury as follows:

	Cases
Under 2 hours	8*
2 — 12 hours	5
12 — 24 hours	2
24 hours to 4 months	7

* 7 had perfect results

I have started motion in these flexor tendon cases usually within twenty-four hours and have used a rubber band, attached to adhesive at the finger tip and at the wrist, holding the finger flexed and having the patient actively extend while the rubber band pulls the finger back into flexion.

Fractures of the Metacarpals

These fractures fall naturally into four clinical (i.e. therapeutic) groups, those of the bases of the second to fifth metacarpals inclusive, those of the shafts of the same bones, those of the necks of the same group, and the fractures of the first metacarpal

Simple fracture of bases of metacarpals two to five This group presents as a

Fig 3 Gauntlet of plaster-of-Paris A—Thumb completely free. B—Edge leaves metacarpophalangeal articulations free. C—Extends to just short of elbow. Should be thin but well-hardened, with minimal amount of padding and accurately molded.

The accumulation of heat from a forty watt bulb is sufficient to produce comfortable and effective temperature with no risk of burn. The light is inside the blanket but outside the sling suspension

whole the simplest picture and best prognosis of the hand fractures in so far as the bone lesion is concerned. Where the bone lesion is merely part of a general crushing of the hand, the problem is the different one of the crushed hand, which is dealt with below

The violence resulting in these fractures is usually of the direct type—a falling object striking the back of the hand, a blow from a hammer or other tool, a dropping window sash, etc. Ipso facto there is usually a considerable amount of soft part swelling, with marked local pain and tenderness. This, in fact, constitutes almost the entire clinical picture, since there is practically never any appreciable displacement due to the firm and extensive metacarpophalangeal and intermetacarpal ligaments covering the bases of the bones. Occasionally indirect violence, such as a fist blow against a hard object,

will result in this fracture, but this is much more apt to produce either shaft or neck fractures. When indirect violence is the cause, the local pain and tenderness are apt to be less marked and more short lived

The sign which is of value in differentiating these fractures of the base in the presence of severe contusion of the soft parts is indirect tenderness. This is

elicited by pressure against the metacarpal heads in the long axis of the bone with the wrist fixed in extension. This gives pain in the fracture site at the base. In the presence of such indirect tenderness, x-rays centered on the bases of the metacarpals and taken in anteroposterior, lateral, and oblique views will show the fracture. Due to the lack of displacement, the oblique views are important, as the lateral view of the hand is usually not of much value by reason of the mutual overlapping of all the metacarpal bases

The treatment of these cases is a matter of attention to soft part pathology. There is usually no reduction needed in the uncomplicated case, and the fracture requires but a ten day or at the most two weeks immobilization in an interior moulded plaster or other splint in slight cock-up position. The pathology in periosteum, ligament, and tendon overlying

thickening to throw out the mechanism of the joint. We are accustomed to think of the normal joint capsular thickenings as the result of healing as having little bearing on ultimate joint function, but we are accustomed to thinking in terms of knees, hips, ankles, wrists, and similar large joints having gross movements. One can readily realize that a pinch of dust in the works of a grand-

trate on the capsular and synovial mechanism rather than on the bone lesion.

This conception of disability causes also makes evident the reason why manipulation of stiff fingers is so frequently ineffective—each manipulation is followed by a little hemorrhage perhaps, a little exudation into the capsular structures certainly, a little ensuing tissue produc-

Fig 1 Lateral and dorsoventral views of phalangeal articulation

A—Lateral view

a—dorsal ligament, b—ventral ligament, c—fibrous and cartilaginous plate in ventral ligament known as the glenoid ligament, d—synovial and subsynovial fold.

Of note are the thinness of the ligaments proper, the laxity of them and the synovial structure allowing free movement in the dorsoventral plane, and the ligamentous attachments at some distance from the joint margin, allowing for play in the same place.

The glenoid ligaments are really thickened fibrous plates which are cartilaginous at their points of attachment to, or merging with, the collateral ligaments. They are grooved anteriorly for the flexor tendons. Normally quite flexible, it takes but little additional thickening or fibrosis to make them stiff enough to seriously affect motion.

B—Dorsoventral view

e—Collateral ligaments, f—synovial and subsynovial fold.

Of note are the relative thickness and denseness of the ligaments as compared with the anterior and posterior ones, the closeness of attachment to the articular margin giving very little play to either side, and the relative scantiness of synovia and subsynovia indicative of little lateral mobility.

Fig 2 Elbow sling suspension

A sling of canton flannel or muslin pinned to suspension sticks suspended from cross bar. Suspension weight in reach of other hand for easy shift of position. Hand and forearm pinned into sling. Thumb free.

father clock would not be a matter of worry. But a pinch of dust in a tiny fine-jeweled Swiss watch would render its mechanism worthless.

Here then is our second lead as to the principles to adopt in treating and evaluating fractures of the hand. In fractures involving the capsule of the joint by proximity or actual invasion, concen-

tion, with further thickening and disability.

In discussing the care of these fractures we shall deal first with simple fractures involving the metacarpals, then simple fractures of the phalanges, and lastly with the compound fractures and crushes as a group.

whole philosophy of the modern conception of fracture treatment is embodied in the handling of this simple lesion, and I have therefore been led to go into some detail in discussing it, since it provides the basis for the rationale of the handling of this whole group of fractures

Simple fractures of the metacarpal shafts These may be due to either direct or indirect violence. Those due to direct violence are apt to be transverse, and to show angulation, usually directed dorsally and open volarly, as their deformity. Those due to indirect violence are apt to be oblique or spiral and add to the angular deformity various degrees of over riding and lateral displacements of the fragments. In either instance there is some shortening of the bone and consequent recession or dropping of the knuckle prominence for the bone or bones involved. Both types may, of course, occur under minimal violence without displacement, in which case the diagnosis is made by local signs plus indirect tenderness elicited as described under fractures of the metacarpal bases. Those showing a spiral line of fracture, which may extend practically from head to base at times, can be produced by purely torsional strain on the tightly gripping hand. As in fractures of the metacarpal bases the soft part pathology is most marked in the cases due to direct violence which in this group, however, constitute the minority.

The principles of treatment are precisely those outlined under the discussion of the metacarpal base fracture. When the fracture shows no displacement, the treatment programs are identical. When displacement exists, the program must be modified in accordance with the necessity for reduction of the deformity and maintenance of that reduction until adequate healing has occurred.

It has been fairly widespread traditional practice to treat fractures of the metacarpals by bandaging the hand and fingers over a roller bandage until such time as union has occurred. I do not believe that under present day conceptions of the purpose of fracture treatment, such procedure is ever justified by any fracture of the metacarpal. If there is no displacement the immobilization of the fingers is undesirable, purposeless, and

may be harmful. If there is displacement, such a procedure tends to maintain or increase it. The practice should be relegated to the limbo of those discarded methods which can be labelled "simple, but ineffective."

If the deformity existing is merely an angular one, and the fracture line is transverse, manual correction can be usually readily accomplished, and the reduction can be maintained by a carefully moulded circular plaster gauntlet with little or no padding, extending from just

Fig 7 Finger pin traction—"head-on" view. Note moderate dorsal cock-up.

proximal to the metacarpo phalangeal joints to just distal to the elbow with the wrist in slight dorsiflexion, and allowing full elbow and finger motion (Fig 3). If the soft part swelling is marked, the physical therapy measures described under fracture of the metacarpal bases, plus, if necessary, suspension in elevation until it is reduced sufficiently to make circular plaster both safe and effective is, in my experience, a better procedure than the attempt to reduce and hold a reduction in the presence of marked puffing of the hand. Even in cases with marked puffing, the use of immediate elevation, constant low degree heat of simple type (Fig 4) and static brush discharge will reduce the swelling within twenty-four to forty-eight hours to a point where circular plaster can be safely and effectively applied. The usual mistakes in the application of plaster are the attempt to substitute voluminous padding or tightness of application for accurate moulding, the blocking of the metacarpo-phalangeal joints, the extending of the plaster to but a short distance above the wrist giving ineffective leverage for

Fig 5 Finger pin traction—palmar view. Plaster gauntlet, "banjo" wire incorporated in plaster, elastic traction with screw adjustment, thin strip aluminum yoke. Plaster should be as light weight as is consistent with rigidity. "Banjo" bar is drilled at intervals. Elastic attached to hooked end of threaded rod passed through drilled hole. Set screw adjustment tightens or loosens pull.

the fracture produces what late and persistent symptoms there may be. These symptoms are local tenderness, a visible "bump"—which looks bony but is usually not—and pain on forceful grasping with the hand or forced flexion of the wrist. The amount of motion at the metacarpocarpal joints is minimal, but is enough to produce pain in forceful movements of the wrist if the ligaments are markedly thickened for a considerable period of time. The periosteal and ligamentous

Fig 6 Finger pin traction—dorsal view

thickening may produce prolonged local tenderness, and the tendon pathology may result in some persistent pain, and thereby some weakness on firm grasping with the hand and forced movements of the wrist.

The best safeguard against the annoying persistence of such symptoms is therapy directed toward the removal of early soft part pathology, before it can become organized into persistent tissue change. Since there is characteristically little or no displacement of the fragments we can remove the splinting for such treatment as often as need be from the beginning. As in so many other traumatic lesions, physical therapy is of value here early. Its value late—two or three weeks after the injury when hemorrhage and exudate have been organized into tissue—is small. Static brush discharge and autocondensation applied within a few hours of the injury may do a great deal to minimize the amount of soft part infiltration. Hot soaks two or three times a day, low millampereage diathermy once or twice a day, if combined with finger exercise within pain limits on a railroad schedule basis—every hour on the hour—for five minutes or so in the hour, represent all that is necessary in the way of active treatment in the first five to seven days. In addition, sling elevation with the hand over the opposite clavicle or shoulder between treatments, or in those with extreme swelling, bed rest with the hand in elevation by a suspension sling beneath the elbow (Fig 2) should be carried out. It is obvious that circular plaster in these cases is a handicap, since it obviates much of the early attack on the soft part pathology which is the basis of late symptoms.

Under such a regime the recovery from a fracture of this type should be both complete and rapid. It would probably be complete under any method of treatment, but in industrial cases the time of convalescence is an all important factor, as has been pointed out. If the part is merely immobilized for two or three weeks, as is a common practice, at the end of that time being subjected to physical therapy, and if the finger exercise is not from the beginning put on a railroad schedule, then one is apt to get the annoying persistence of symptoms referred to above. It seems to me that the

exercise is carried out as in the preceding group. This method of treatment allows of a maximum maintenance of function during the course of fracture healing and a minimum of disability time after the fracture is healed. Its only disadvantage is the theoretical risk of infection due to the use of pins. With decent surgical technic, and with the pin sites sealed by a cotton collodion dressing, and with adequate supervision of the post reduction care, this should not be sufficient to constitute a valid objection to the method. If it is considered inadvisable to use skeletal traction, some form of skin traction must be substituted. It has the definite disadvantage that it is less effective mechanically, that it immobilizes all the joints in the affected finger, that it is apt to keep slipping, and that attempts to apply it extensively and firmly enough to

prevent slipping may result in circulatory difficulty with skin damage or gangrene. Some of the methods which can be utilized are illustrated in Fig 11, with note as to their good points and dangers. Under this method the results are less apt to be satisfactory anatomically, and the convalescence time is apt to be longer. Occasionally, with marked deformity, an open reduction is necessary through inability to get satisfactory reduction by other means. This is rarely true when only one metacarpal is involved, and almost never true when skeletal traction is used. Fixation at operation is difficult, as catgut, silk or wire usually has to be used, and the fixation accomplished is not enough to allow of active motion without splinting, it is our feeling that operative reductions in these cases should be avoided, and can be if skeletal traction is adequately used.

Fig 11 *Skin Traction*

A—Multiple spiral strips covered by Ace type of woven elastic bandage. Spreader is essential. Holds well but there is possibility of circulatory interference.

B—Glove finger (leather) glued to finger. Ten cent piece in finger tip of glove acts as spreader. Holds well but less chance of circulatory disturbance.

C—Lateral adhesive strips with or without Ace bandage—*Not to be used*—lateral application is serious circulatory risk.

D—Anterior and posterior strips do not hold well

E—Japanese finger basket holds well, but there is definite circulatory risk.

Fig 12 A—Deformity of metacarpal neck fracture. Note palmar angulation of head on shaft and the impaction of the palmar aspect. An apparent paradox in functional disturbance exists. One would assume that with flexion deformity, there would be limitation of extension. But extension (a) is full, and the limitation is in flexion (b) due to the soft tissues crowding forward and giving mechanical interference.

B—Method of reduction. A weavers clamp of metal, having a pivoted flat button at (a) is screwed down tightly over two small felt pads (b). A sudden tilting of the clamp as indicated by arrows, the hand being held fixed by an assistant forces the head fragment backward as it also tends to disimpact it.

Fig 13 *Tendency of roller bandage to increase the deformity.* The bandage, following the direction of the small arrows produced the general effect of arrow A with the tendency to force B on the head fragment.

maintaining correction, and the substituting of amount for quality of plaster, resulting in a heavy, cumbersome, and disabling weight. Finger exercise within pain limits on the "railroad" schedule previously referred to is essential from the beginning, and intermittent elbow exercise as well. When not exercising, sling elevation of hand as previously described is indicated. The sling is gradually discarded so that by the end of seven to ten days the patient can be allowed to use the hand in its plaster encasement for everything—in fact, must be urged to do so. Under this method such a transverse fracture, with angular displacement, can be returned to clerical work wearing his gauntlet in a week or so, and ten days to two weeks may see many manual workers at least at light work. The plaster is worn until union occurs—three to five weeks on the average. If active use of the hand and arm has been enforced during this period there is but little further disability time, and the need for late physical therapy is minimal. If the arm and fingers have been allowed to remain inactive, swelling on use, stiffness of fingers, wrist and elbow, and prolonged convalescence may be the result.

When an oblique or spiral fracture with overriding exists a different procedure is called for. Reduction and maintenance of reduction in these cases calls for a traction force. It can be applied in various ways. The best way is that which will allow of the minimum of interference with function during the process of the bone repair. We have found that to be skeletal traction by means of a wire passed through the proximal phalanx, as close to the web of the fingers as possible. A thin flat aluminum loop is then placed over the ends of the pin, and through a rubber band traction is applied by a banjo splint. The plaster casing in which the banjo is held has a palmar forward projection at the proper cock-up angle to correct any tendency to angulation when combined with the proper angle of traction. Enough tension is applied to the rubber band traction to correct overriding. The plaster incasement in this instance should also extend to just below the elbow, and should allow full motion of the fingers not in traction (Fig 5 to 10). The use of skeletal traction through the proximal phalanx will allow of early motion in the two interphalangeal joints of the affected finger. Sling elevation and

tion of this rather arduous treatment. In a manual worker a moderate amount of depression into the palm may constitute a definite indication for the treatment described particularly in the right hand in right-handed individuals, and the left hand in the left-handed. As will be noted a small amount of traction only is needed. It has therefore hardly seemed worthwhile to use the skeletal form, although if ap-

pulp, just distal to the end of the distal phalanx as recommended by Böhler. The former I have employed and consider unsatisfactory by reason of both the discomfort entailed and the nail damage resultant. The latter I have never employed. It has been highly recommended by Bohler, and it is claimed to be painless and without risk of infection or soft part slough. I have seen it in operation in Germany,

Fig 17 A—Common direction of traction and position of fixation in first metacarpal base fractures. B—Tautly stretched musculature. C—"Snuff box."

Fig 18 Proper direction of traction and position of fixation. (See text)

Fig 19 Types of marginal phalangeal fracture

A should be started on intermittent active motion promptly. B is subluxated, and replacement with immobilization to maintain position is apt to result in stiffness. C is the so-called baseball finger in which the extensor tendon attachment is torn out and with it a small fragment of bone. Hyperextension immobilization works well in this type of case.

In all these lesions the capsular lesion is by far the most important.

plied through the proximal phalanx, it has all the theoretical advantages which it has in the shaft fractures. The immobilization time is short—10–14 days—and for this reason wire traction has not been felt to have the practical value which it possesses in theory. In the shaft fractures, where three to four weeks immobilization is the rule, the situation is different. The traction is therefore made by one of the means of skin traction (Fig 11).

There are two other forms of traction which may be employed in these cases, as well as in the phalangeal cases to be considered below. One is by silk or wire loop through the finger nail. The other is by a wire loop passed through the finger

Austria, and England. I have never been able to convince myself that it had anything but disadvantages as apposed to skeletal traction. I am, therefore, not ignorant of the method, but am completely inexperienced in its use, and have nothing to support my aversion to it but a conviction that it is not as effective as skeletal traction and must be at least as dangerous, if there be danger in either method.

Fractures of the first metacarpal. These are listed as a separate group because of the fact that they involve the thumb, and because their treatment is commonly carried out on unphysiological and unsound mechanical lines. The same principles and the same methods in general are car-

Fractures through the metacarpal necks
These are commonly caused by indirect violence, due to a blow directed against the knuckle. The common story is a fall on the back of the hand or the clenched fist, or a blow on the back of the hand. The real etiology of the majority of them is a blow of the clenched fist landing on an unexpectedly hard portion of another individual, such as the skull,

and sling elevation will allow of progressive active motion with a short disability time. If the angulation is marked, and the prominence in the palm easily palpable, reduction and maintenance thereof is indicated. This certainly can not be accomplished by bandaging the hand over a roller bandage. If anything this serves to maintain or increase the deformity. The fragments are usually impacted and hy-

Fig 14 Pure hyperextension (A) obviously tends to increase the deformity. Theoretically traction in hyperextension (B) should tend to correct the deformity. Actually there is no such appreciable effect.

Fig 15 A—Plaster gauntlet extending well up towards elbow, with right angled palmar turn distal to metacarpophalangeal junction. Traction C uses phalanx as a lever over fulcrum B with resultant effect D tending to lift head dorsally. End A of plaster dorsally holds the shaft fixed.

Fig 16 Three types of first metacarpal base fracture

A—requires traction and fixation as described in text. B is susceptible to manual replacement and any adequate fixation. C requires the same treatment as A, but is far more difficult to get satisfactorily reduced, and involves the carpo-metacarpal joint.

or, due to inadvertently missing the target altogether, landing on an adjacent wall or similar object. The characteristic deformity is a forward angulation of the head into the palm with a "dropped knuckle." The characteristic disability, when there is one, is some limitation of volar flexion in the metacarpo phalangeal joint, and the complaint of pressure pain over the palmar prominence when a hammer, wrench or screw driver has to be used. It is comparable to the metatarsalgia which is characteristic of abnormal weight bearing on one of the metatarsal heads in disturbances of the so-called anterior metatarsal arch in the foot. These fractures are, as might be expected from the nature of the violence, usually impacted. If the angulation is but slight a few days immobilization with the early physical therapy already alluded to

per-extension of the phalanges tends to increase the deformity, although it is commonly used as a method of reduction. The distal fragment is small and manual reduction is difficult, frequently impossible, for this reason. We have found reduction, where indicated, best accomplished by the means illustrated in Fig 12 to 14. When reduction is secured it can best be maintained by the mechanism illustrated in Fig 15, the same mechanism utilized in a comparable fracture, that of the supracondylar fracture of the femur. As will be noted, active use of the fingers not involved is possible, and the treatment is in principle and practice that already indicated for the other groups. In a clerical worker, if the "dropped" knuckle does not in itself constitute an unsatisfactory result, considerable deformity should be present to warrant the institu-

maintained, stiffness of the involved joint may be permanent. The possibility of this outcome when fixation is practiced is great. The possibility is minimized if banjo splint elastic skeletal traction is used with the plane of the banjo traction changed several times daily, with active motion against the traction in its various positions on the "railroad schedule" previously referred to, and with early elevation and constant low heat to get rid of as much hemorrhage and exudate infiltration in the tissue as possible. (Fig 5 to 10)

Primary operative excision or replacement of the avulsed fragment and suture of the torn capsule has been suggested and attempted, but the results are not at all good, since the operative trauma added to the trauma of injury merely increases the amount of thickening of the delicate capsular structures in the healing process with resultant stiffness.

It is important to realize that the mere thickening occasioned by the normal healing process in the capsular lesion may be sufficient to cause some stiffening of the joint, and that the end result is dependent far more on this factor than on the x-ray picture.

Crushes and Compound Fractures

From what has already been mentioned in reference to the importance of soft part scarring and its effects on the function of tendon, joint capsule, and synovial pouches, it is obvious that compounding of hand fractures is a serious complication, both from the standpoint of the amount of new tissue produced and from the risk of super-added infection to which bone, joint, tendon, tendon sheath, and the closed hand spaces are exposed. The actual bone lesion fades into relative insignificance in comparison with these risks. Even when crushing of the tissues without compounding complicates the fracture or fractures, the fibrous tissue production in the crushed tissue in and about the various structures detailed above is of much more import to us than the actual bone lesions. In compounding wounds, complicating hand fractures early, gentle, but thorough debridement of all dead and devitalized tissue is essential. It must be done with care and pre-

cision and a minimum of violence. Tendon and nerve tissue must be proven intact, or if damaged, must be repaired after the debridement but at the time of primary treatment. Late repair of hand tendons is difficult, late repair of hand nerve injuries not only difficult, but frequently impossible. In order that scar tissue shall be kept at a minimum and that tendon and nerve repair, if done, may have some chance of successful outcome, the prevention of infection in the compounded, and often crushed, tissues is of paramount importance. For this reason I shall here briefly recount an adequate method of debridement.

Having determined that circulation to the hand as a whole is intact, a tourniquet is applied above the wrist. The wound itself is then packed gently but firmly with sterile packing, and a green soap and water cleansing of the skin of the whole hand is done, using lots of soap and water, plenty of time, but no violence. The old type cleansing by a vigorously wielded brush added trauma to that already present. It is better to substitute time and cleansing material for vim and vitality. If the injury has been occasioned by machinery, and oil and grease are present, benzine may precede the use of soap and water. Following the soap and water cleansing such shaving as may be indicated for dorsal

Fig 21 Suspension traction detail (Compare with Fig 5 to 10)

Fig 20 Suspension substituted for the banjo splint traction

ried out as in other metacarpal fractures. Fracture of the base of the first metacarpal is commonly marked by a greater or lesser degree of adduction deformity of the shaft on the base, in contradistinction to the fractures of the bases of the other four metacarpals. When this is marked, or when the fracture line invades the joint, correction of the deformity is indicated (Fig 16). When it is mild and the joint surface is not involved, the treatment as for other metacarpal fractures without displacement is in order. The traction methods, using the banjo splint, elastic skeletal traction by preference or others by virtue of necessity, are the indicated means for correction and maintenance of correction of deformity. But this is commonly practiced (Fig 17) against the tightly stretched adductors and flexors of the thumb, and in my own experience has been very unsatisfactory in its results. In addition, any stiffness which may result hinders adduction and flexion of the thumb, essential motions for a useful hand. I have found that the best anatomical and functional results are secured by traction applied, as shown in Fig 18, with the thumb adducted and flexed parallel with the plane of the extended fingers

and pointing in a line passing above the tip of the little finger. In this position all the finger tips can be applied to the tip of the thumb, and if there is any limitation of flexibility in the metacarpophalangeal joint it is in adduction and extension, much less important and valuable movements. When the first metacarpal shaft is involved with displacement, the same indications are present. It is interesting to note that by the use of skeletal traction through the first phalanx, the active use of function in the interphalangeal joint can be preserved, and apposition of the finger tips can be practiced throughout the healing of the bone lesion.

Simple Phalangeal Fractures

These are by far more disabling than the metacarpal fractures. The anatomical and physiological reasons therefore have been presented in the introduction to this paper. The principles involved in treatment of the shaft fractures are precisely those presented for treating fractures of the metacarpals, and are carried out by comparable methods. Those without displacement are treated as are the similar metacarpal fractures. Those with displacement are best treated by traction methods, and the same remarks apply to them as apply to the metacarpals. The actual appliances are shown in Fig 5 to 10. The prognosis in simple shaft fractures should be good by these methods both as to end result and as to the time element involved. The treatment following the reduction by elastic traction in the proper planes is that described for metacarpal fractures similarly treated. Finger stiffness is more apt to follow rigid immobilization without traction because of tendon fixation and soft part thickening by reason of organized hemorrhage and exudate.

There are in the simple fracture group, however, a class of fractures prone to give trouble. They are illustrated in Fig 19 and represent an avulsion of the articular margin with or without subluxation of the finger. The reason for the disability in these cases lies in the soft part changes in the torn capsule and synovial folds and the glenoid ligament disturbance, and even when adequate reduction has been secured and is shown by x-ray, and has been

Summary

Fractures of the hand are a source of frequent severe disability in industry

The causes of disability lie in the tendon and joint changes rather than in difficulties with the bone lesion

These changes are part of the normal healing process, and are disabling in the hand because of the delicate mechanism of the structures involved, which may be thrown out of gear by the thickening occasioned by normal healing

Compounding and crushing greatly increase the risk of disability

Treatment methods embodying manual reductions and plaster immobilization are least calculated to produce good results

Treatment methods involving skeletal traction, active mobilization within pain limits, and early attack on soft part pathology are best calculated to produce good results

Where joint capsule is involved some disability may be unavoidable, even under the best of treatment

Meticulous attention to detail, frequent observation, and untiring patience are among the most important factors in securing satisfying results. End results must be evaluated economically from a dual standpoint—that of the nature of the result, and the time required to secure it

Progress Report of Subcommittee on Curricula Study, M. O. Magid, M.D., Chairman

1 Diseases of the Oral Cavity of Medical and Dental Interest, Samuel Feldman, M.D. Discussion by Leo Spiegel, M.D. and Henry Dunning, D.D.S., M.D.

2 Medical Problems in Orthodontia. Bernhard W. Weinberger, D.D.S. Discussion by Ralph Waldron, D.D.S. and Edward Mason Griffin, D.D.S.

2 15 P M CLINICAL MEETING

Presiding, Henry Joachim, M.D., Pres. Kings County Medical Society and Wm J. Buntin, M.D., Pres. Richmond County Medical Society

1 Lesions in Oral Cavity. Presentation of Patients—Clinical Pathological and Roentgenological data. Adolph Berger, D.D.S.

2 Vitamin Deficiency Conditions in Children—Presentation of Patients. Reuben Turner, M.D.

3 Clinic—New York Institute of Clinical Oral Pathology. Cases to be presented by Raymond Gettinger, M.D., Herman L. Reiss, D.D.S., and Meyer L. Rosoff, D.D.S.

4 Radical Antrum Operation. Cases illustrating the superiority of the Intranasal Route over the Canine Fossa Approach. Simon L. Ruskin, M.D., and Max Halle, M.D.

Note Discussion or questions after each group of cases

8 15 P M STATED MEETING

First District Dental Society

Presiding, Jacob B. Schneer, D.D.S., Pres. First District Dental Society and Chas. E. Farr, M.D., Pres. N. Y. County Medical Society

1 Executive Session.

2 The Responsibility of the Dental Profession in the Early Diagnosis of Intraoral Cancer, Hayes E. Martin, M.D.

The object of this meeting is to call attention of the members of both professions to the close relationship existing between systemic and dental diseases and to stimulate more interest and greater cooperation between the practitioners in the care of their patients, to the end that the public shall receive better health service.

The meeting will be held under the auspices of the First District Dental Society, Second District Dental Society, Bronx County Medical Society, Kings County Medical Society, New York County Medical Society, Queens County Medical Society, and Richmond County Medical Society.

M. O. MACID, M.D., *Chairman*

ORVILLE S. LONG, D.D.S., *Vice Chairman*

ROY D. RIBBLE, D.D.S., *Secretary-Treasurer*

ALBERT F. R. ANDRESEN, M.D.

THEODOR BLUM, M.D., D.D.S.

WILLIAM MCGILL BURNS, D.D.S.

LAWRENCE J. DUNN, D.D.S.

JOHN STANLEY KENNEY, M.D.

FRANK R. MAZZOLA, M.D.

MORTIMER B. GENAUER, M.D.

injuries is done. The skin is then cleansed with alcohol, and then with ether. A 3½ per cent solution of iodine is then applied, allowed to dry, and the wounded area draped. The sterile plug is then removed from the wound, and a meticulous removal of dead, grossly contaminated, or frayed-out tissues is done, using a sharp scalpel and not a scissors. The latter crushes tissue. This is done in layers circumferentially, changing the instruments for fresh ones for each layer, or cleansing them between layers. The skin, the subcutaneous tissue, the fascial planes, the subfascial and tendinous planes, and the fracture site are done as separate layers. By changing the instruments between layers we keep from insuring the fact that surface contamination will be carried to the depths of the wound. During this procedure we carefully note the condition of tendons, nerves and, if exposed, joints. The wound is then lavaged, using a small soft-tipped rubber catheter with gallons of normal saline—not with a few ounces. If grease is present in the wound itself, this is preceded by ether lavage sufficient to remove it. There is no use of antiseptics which may injure the tissues as well as organisms, and we depend entirely on the mechanical factors of meticulous debridement and prolonged mechanical lavage of the surfaces left after debridement. The catheter is inserted to the depths of the wound and the lavage carried on from the depths outward. The saline container is elevated sufficiently so that a fair amount of force is given to the stream. Let me emphasize the point that gallons, not ounces, of saline is necessary. The speed of the procedure is of much less importance than the meticulous nature and completeness of the debridement and the thoroughness of the ensuing lavage.

Time becomes of paramount importance, however, in reference to the interval allowed to elapse between time of injury and the time of debridement. A wound treated within a few minutes to an hour of injury presents the problem of getting rid of surface contamination. A wound treated three, four, five or more hours after injury often represents a futile effort to get rid of infection which has actually penetrated into the tissues beyond our reach. We should think of debridement in terms of minutes after injury in calculating our chances of avoiding infection, not in terms of hours.

Following this debridement and lavage, such tendon and nerve injuries as are

present should be repaired as simply as possible. The tourniquet is then removed, and any bleeding points becoming apparent are clamped and ligated. A few loose sutures may then be used to bring skin edges into loose approximation. A few only should be used, enough to prevent wide gaping of the skin, and no suture should ever be placed which causes tension. If the skin edges can not be loosely and easily approximated, they should be allowed to gape and the wound very loosely packed with vaseline gauze. If it has been possible to approximate the skin edges loosely, vaseline gauze strips are laid over it and a loose fluffy dressing applied. We are now ready to treat the fracture *per se*. The treatment of the fracture is carried out preferably by the use of the traction methods described for simple fracture, using at first bed rest with skeletal traction in suspension as illustrated in Fig. 20 and 21 by preference, to be followed by banjo splint elastic traction as illustrated by Fig. 5 to 10 when wound healing and subsidence of swelling and infiltration allows. The general care of the fracture is, once the wound is satisfactory, exactly that detailed for the simple fracture. It is of course unnecessary to state that a very careful watch must be kept for the first three or four days for evidence of beginning infection, and that if it presents itself, it must be adequately and promptly dealt with. The skeletal suspension, without plaster or other splint, lends itself ideally to the observation and care of the soft part damage.

Brief mention should be made of one common form of compound injury—that of the nail if it is loose, and should, I avulsion or loosening of the nail, but with separation and comminution of the distal portion of the terminal phalanx.

The debridement should be done here as elsewhere, but should include removal of the nail if it is loose, and should, I believe, always include the *removal* of the separated distal fragments of the phalanx. Quicker convalescence, less chance of painful and tender finger ends and of stiff terminal phalanges, and less chance of infection are the advantages of this procedure. It has, so far as I know no disadvantages.

sistance through a widening or narrowing of arteries and arterioles in which the greatest resistance lies. Widening of the capillaries alone can not increase the blood flow of an organ very materially since the capillary resistance itself is only about a tenth of the general resistance of the arterial stream bed. Mechanisms for vascular widening or narrowing serve for the regulation of heat loss, of the functions of the sexual apparatus, and for the nutritive requirements of different parts. Some of these, like the blood flow through the sexual organs and for purposes of heat regulation, are mediated apparently through definite nerve paths. The factors for the distribution of blood for other purposes are less definite and in addition to nerve impulses and the effects of hormones from endocrine glands, we must consider other humoral or chemical factors, especially the acid base equilibrium in the tissues, result of lack of oxygen, effect of intermediary products of metabolism, and influence of certain substances like histamine, acetylcholin, and adenosine, definite chemical substances that exist normally in certain body tissues, probably in loose combinations with larger molecules from which it is thought they may be split off and exert in the normal physiology of the body effects that can be demonstrated in the study of their pharmacology. This rather special subject of study and research is dubbed by Sir Henry Dale³ autopharmacology or the chemical regulation of certain functions by natural constituents of the tissues. Still other materials have been studied by English⁴ and German⁵ workers, and by Major⁶ in this country—tissue extracts that show a definite vasodilating action but which are of unknown chemical composition. Kallikrein is still another highly active vasodilator substance first obtained by Frey and Kraut⁷ from normal urine and later found to exist in relatively large quantities in the pancreas. These workers considered and spoke of it as a circulatory hormone but its status is still unsettled.

Let us return for a moment to the minute volume output of the heart in order to emphasize a regulatory mechanism of great importance. We appreciate the importance of regulation when we realize that the heart minute volume at rest in man is about four liters and that with in-

tense physical work it mounts to twenty liters or more. There are several regulatory mechanisms at work but the point of primary importance is not a change in the heart action itself nor in its nervous excitations, but in the diastolic filling of the heart which in turn depends upon the amount of blood flow in the large veins. The healthy heart throws out all the blood that flows into it from the veins, it cannot expel more than it receives. The regulation of the venous flow back to the heart hence assumes a very important aspect. Here must be considered the veins themselves, intrathoracic pressures, and the so-called blood storing organs or blood depots, notably the spleen and the liver. The veins themselves are under nervous and hormonal control. The spleen is known to contract during physical work, after blood destruction, in anoxemia, and after adrenalin. Similarly the liver empties under the influence of adrenalin even up to sixty per cent of its weight in blood. With a widening of the veins, filling of the store houses, and retention of blood in the periphery, the venous pressure falls, the return flow to the heart is insufficient, the heart is poorly filled, the minute volume output sinks, the arterial blood pressure falls, and we have the setting for peripheral circulatory failure familiar in acute infectious diseases, surgical and traumatic shock, histamine shock, etc. Henderson⁸ and his associates have recently described a technic for the determination of pressure within a muscle. They believe that the tonic tissue pressure throughout the body combined with the negative pressure in the thorax that is largely dependent upon the tonus of the respiratory muscles determine the "effective venous pressure" that in health assures the venous return. On this basis, failure of the circulation in illness and after physical injuries is largely due to diminution of general body tonus and stagnation of blood in the flaccid tissues.

In the current literature, there are quite a number of articles⁹ dealing with the circulation time or velocity of blood flow, terms that are used almost interchangeably. Since the fundamental work of Blumgart¹⁰ and Weiss (1927), several different methods have been devised. The circulation time of the blood may be defined as the time required for a particle in

CERTAIN ASPECTS OF BLOOD FLOW

THOMAS P. SPRUNT, M.D., *Baltimore*

It is usually stimulating and helpful though not necessarily immediately fruitful to renew our acquaintance with the fundamental factors and to review recent additions to the knowledge of subjects with which we are working in medicine.

There is no system of the body of greater importance to the physical therapist than the circulation of the blood and the various mechanisms that control and regulate it. He may be called upon to aid in the treatment of patients with heart disease, arterial hypertension or hypotension, arteriosclerosis, other diseases of arteries or veins, and in addition, he is constantly aspiring to influence the blood flow favorably in his efforts toward the amelioration of diverse ailments.

The purpose of the circulation and the object of all its regulatory mechanisms is that each tissue should at any moment receive the blood supply necessary for its work. For this purpose we have the anatomical system of the heart, the arteries, arterioles, capillaries, venules, veins, and their own intrinsic blood vessels and nerves.

From the physiological angle we think in terms of the minute volume output of the heart, blood pressure, blood velocity and circulation time, blood volume flow, peripheral resistance, arteriolar or capillary constriction or dilatation, venous pressures, blood depots, blood volume, and venous return to the heart.

The regulating factors of the circulation are numerous, very complicated, some of them well-studied, others little known, and probably still others entirely beyond the present conception of the physiologists.

The peculiar properties of the heart muscle and its regulatory mechanisms are perhaps the best studied and best known of all but with these we shall not be immediately concerned. Of vast importance for the whole circulation is the autonomic nervous system with its cardioaccelerator and cardioinhibitory fibers, its vasoconstrictor and vasodilator fibers involving the arteries, arterioles, capillaries, and

veins. There are afferent and efferent impulses mediated through numerous reflex arcs with centers in the brain and the spinal cord, and with axone reflexes in the periphery. There are certain peripheral centers of nervous activity, especially the carotid sinus that exerts a commanding influence upon the whole circulation and is now the object of intensive research.¹ The nerve fibers of the carotid globus and in the bulb of the internal carotid, together with the depressor nerve from the root of the aorta are all afferent nerves, very sensitive to changes in pressure within the aorta and in the carotid vessels. Variations in these pressures set up afferent nerve impulses that result reflexly in variations in the heart rate, in blood pressure and in blood flow, in addition to their effect upon the respiration and other physiological phenomena.

The larger arteries and veins are probably in large part controlled through autonomic nervous impulses, but even at this level it is impossible to differentiate entirely such impulses from the effects of well-known hormones from endocrine glands, notably epinephrin and pituitrin. Of the many physiologists who have contributed to this knowledge, the work of Cannon² is particularly important and interesting in emphasizing the role of epinephrin in mediating and accentuating sympathetic nervous effects. As we approach the peripheral arteries, arterioles, and capillaries, our knowledge is less assured for in addition to the maintenance of the heart minute volume and of the general blood pressure that influence the general circulation, we must consider the additional mechanisms that divide up the minute volume output of the heart according to the need of the different and separate organs. During intense work the amount of blood to an organ or tissue is increased several times over that which occurs during rest and the question arises how this variable blood flow is brought about. Here there is generally recognized a differential change in the peripheral re-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

meters of blood per 100 grams of tissue or organ per unit of time. The blood supply in different organs for each 100 grams of tissue per minute is given as follows:¹⁸ Stomach 21 c.c., intestines 71 c.c., spleen 58 c.c., liver, arterial 25 c.c., liver, venous 59 c.c., liver, total 84 c.c., brain 136 c.c., kidney 150 c.c., thyroid gland 560 c.c. By the use of the calorimeter method the blood flow through the hand of a healthy young man has been found to be about thirteen c.c. per 100 grams per minute, and for the foot about one-third to one-half that in the hand. There is an interesting comparison at varying degrees of temperature. At 32° C (approximately the normal temperature) the flow of blood in the hand was thirteen c.c. per 100 c.c. of tissue per minute. At 26° C the flow was 5.5 c.c. of blood per 100 c.c. of tissue per minute, and at 46° C the flow was 26 c.c. of blood.

Of great interest to us, though in quite a different direction, is the recent article by Allen¹⁷ on how arteries compensate for occlusion, an arteriographic study of collateral circulation. Such demonstrations emphasize the abundant provision the body has made for collateral arterial circulation and recall the experiments of Leriche¹⁸ some years ago in which he showed that portions of all the major arteries in dogs, even including a part of the aorta, might be resected at the same time and the animal's circulation be handicapped very little.

The study of the peripheral circulation, arterioles, capillaries, and venules, is of great interest, and you are probably familiar with the various methods in use. Here again are used the plethysmograph, calorimeter, and microscope for the study of capillaries, skin color charts, venous pressures, and skin temperatures. You are doubtless familiar with Kovac's¹⁹ work in capillaroscopy and with Bierman's²⁰ recent summary of the potentialities of skin temperature studies. Elliot²¹ has recently published a paper on the study of acrocyanosis in which he has devised ingenious charts for the comparison of skin color adapted somewhat from suggestions made previously by Lewis. Grant²² has recently studied the return of tone in capillaries and arterioles after complete denervation of

the part. He believes that this regain of tone is due to a substance circulating in the blood of the nature of a hormone and having an action quite similar to that of epinephrin, but it is present and its action persists even after the removal of the adrenal glands. The work of Sir Thomas Lewis²³ ten years ago on the blood vessels of the human skin and their responses remains a classic. You will recall that as a result of his experiments he found that numerous and widely different forms of stimulation yielded in common three distinct events. These were (1) the primary and local dilatation of the minute vessels of the skin, (2) widespread dilatation of the neighboring strong arterioles brought about entirely through a local nervous reflex, and (3) locally increased permeability of the vessel wall. In explanation of this complex mechanism, he postulated the release of a histamine-like substance and considered it a normal metabolite that is responsible for many of the normal vascular reactions as well as for those occurring under conditions of stress. These studies, it seems to me, make it seem quite probable that many of the reactions of the skin and other tissues to physical therapeutic procedures are really defense reactions on the part of tissues to outside agencies and are nonspecific as far as the particular therapeutic method is concerned.

If you should be interested in following somewhat further the modern conception of the regulatory mechanisms of the circulation, I would refer you to two interesting summary articles that appeared last year: one by Fleisch²⁴ on the physiological mechanisms, and the other by Bickel²⁵ on the regulation of the circulation in pathological states.

In a brief paper, one can but touch upon the important trends in physiological research concerning the circulation. It may be useful to us to realize the complexity of the subject and the confusion of the multiplicity of regulating factors that we may influence in our daily therapeutic procedures. Certainly the more the physiologists can discover and the more we can learn from them, the more fruitful should be our efforts.

the blood stream to pass between two chosen points. It is obvious then that no figures concerning circulation time are of any significance until the two chosen points are specified. The circulation time between such points is dependent upon the mean velocity of the blood, hence an increase in circulation time in any given area is significant of a decreased velocity of blood in that area, and vice versa. Most methods are based upon the principle of injecting into a superficial vein some relatively harmless material that can readily be detected at some distant point in the circulation. The Mayo Clinic workers inject a radioactive substance into the jugular vein and detect the passage of this substance through the femoral artery by means of an ionization chamber closely applied to the artery. The arm to lung time may be detected by injecting a small amount of ether into a cubital vein and detecting the first odor of ether on the breath. The arm to face time is determined by the injection of histamine and the detection of a flush on the skin of the face when the capillaries in that region are reached. Similarly the arm to tongue time may be estimated by the use of decholin or saccharine, the end point being the distinctive taste. In the same individual under uniform conditions, the velocity of blood flow is relatively constant. It varies of course with different physiological conditions and also in various pathological states. Of the latter, the velocity of blood flow is markedly retarded in cases of marked heart failure and in the incipient stages of this condition the retardation of the blood flow may be one of the earliest detectable indications. Blood velocity is retarded in myxedema with its slow rate of basal metabolism and in polycythemia with its marked increase in viscosity. The rate is greatly accelerated in hyperthyroid states and in fever, both spontaneous and therapeutically induced. The influence of therapeutically induced fever on the velocity of blood flow has been studied by Kissin and Bierman,¹¹ and again recently by Kopp.¹²

From the physiological standpoint, according to McCracken¹³ and his associates, the velocity of the circulation is increased after exercise and during digestion. It is also definitely accelerated after chilling to a degree productive of shiver-

ing and after exposure to an environmental temperature sufficient to elevate the rectal temperature of the body. They report also the effect of various drugs on the circulation time. Very interesting observations were those by Herrick, Essex, Mann, and Baldes,¹⁴ and also McCracken, Essex and Sheard¹⁵ on the influence of the digestion of food in dogs on the blood flow in the femoral, carotid, and mesenteric arteries, and the external jugular vein. For the determination of the volume rate of blood flow in these various vessels they made use of the modified thermostromuhr method of Rein and for the circulation time the ionization method above mentioned. It seems to have been assumed in physiology that during digestion blood is shunted to the digestive tract at the expense of the blood flow elsewhere. Contrary to current belief however these investigators found that the blood is not diverted from the somatic tissues to the visceral organs during digestion. Instead of a decrease in blood flow in the femoral and carotid arteries and the jugular vein, there is a marked prolonged increase during the digestive cycle. This was true also in the mesenteric arteries. The time of the onset and the duration of the increased flow was influenced by the character of the food taken, but the magnitude was relatively the same regardless of the type of food ingested. In general the highest values for blood flow obtained during digestion were about twice those obtained after an eighteen hour fast. The increase in blood flow following a meal was accompanied by an elevation in the pulse rate and by a shorter circulation time. Such a finding would seem suggestive of the idea that under various physiological conditions there may be less differentiation in the distribution of blood flow than we have been accustomed to believe.

Other methods of estimating blood flow include the use of different forms of the stromuhr, the use of the plethysmograph, and especially for an extremity the calorimetric method since the rate at which heat is dissipated from the hands or feet (e.g. into the water of a bath) will be directly proportional to the rate of movement of the blood to these parts. Instead of expressing results in terms of velocity of blood flow the figures are often transposed to read so many cubic centi-

GONOCOCCUS FILTRATE (CORBUS-FERRY) AS A SKIN SENSITIZATION TEST FOR GONORRHEA

CLYDE K. CONRAD, M D , *New York City*

The American urologist has, in the last few years, added another preparation to his armamentarium. Corbus-Ferry gonococcus filtrate is enjoying an enviable role as a specific antigen, an antigen which stimulates antibody formation through skin immunity. There is a very rapid accumulation of literature relating to the success of this product. One is led to believe that here at last is a specific aid in the treatment of gonorrhea.

The specificity of this type of antigen therapy immediately suggests the feasibility of using it as a diagnostic aid in obscure and residual types of gonorrheal infection.

There is no doubt that the diagnoses of acute gonorrheal urethritis, in the majority of cases, is a simple and comparatively easy procedure. However, a certain number of cases are not so easily diagnosed. In the obscure or residual type of infection a skin sensitization test, for the presence or absence of a gonorrheal infection, would have a very definite value.

It was decided to test the value of this filtrate as an aid to diagnosis. One hundred male cases were carefully selected, fifty cases gave a history of never having a gonorrheal infection, fifty cases gave every clinical and laboratory evidence of having a gonorrheal infection in various stages of complication or cure. These cases were given an intradermal injection of Corbus-Ferry gonococcus filtrate. Concurrently they were given a dose of the bouillon and normal saline used in the preparation of the filtrate. The dose and site of medication being the same in each case. The dose of each ingredient used was 1 c c. The extent of the reaction was measured each twenty-four hours until it entirely faded.

Chart I shows fifty cases having gonorrhea with positive smears. In this chart ninety-eight per cent of the cases show an average of 2.32 cm. of reaction forty-eight hours after injection.

Chart II shows fifty cases never infected with gonorrhea. In this chart only eighteen per cent of the cases show an

CHART I—GONORRHEA WITH POSITIVE SMEARS (50 CASES)

CHART II—FIFTY CASES NEVER INFECTED WITH GONORRHEA

LOVE LAUGHS AT LAW SMITHS

The Montana doctors warned the law-tinkers at the state capitol, it seems, not to pass their brass-bound marriage law, but the legislators thought they knew it all and threw the doctors' advice out the window. Now they wish they hadn't. They were trying to keep up with the procession of states that require medical certificates of fitness for wedlock, and evidently thought that while they were doing it they might as well get the jump on the rest and leave the procession a mile behind. For marriage is not what it was in grandpa's day.

It used to be that a minister, a willing couple, and a ring were the only prerequisites for a first-class wedding. Seldom did a physician get tangled in the process, except as a groom or guest.

But times have changed, says *Medical Economics*. Today more than half the states have statutes which bear directly on the physical fitness of those about to marry.

In some of these states,* physicians are as essential to wedlock as are ministers and ritual, court clerks and licenses. Brides and grooms alike must prove their freedom from venereal and other diseases by producing a certificate signed by a licensed physician. Provision is made for a fee of from three to five dollars, varying with the state.

This year Montana felt its lack of a fit-to-wed law. It went the limit, there-

fore, and enacted one (effective July 1) which demands that a doctor certify every prospect for marriage license as being *entirely* free from infectious, communicable, and inherent diseases. Immediately people ceased getting married in Montana. No physician would issue the type of certificate required and run the risk of being discredited afterward, when some latent disease, not apparent at the time of the examination, cropped up again. Patients were advised to wed in other less stringent states.

Montana doctors criticized their legislature freely for not consulting the state medical association before enacting the "gin marriage law."* For a while after it was passed it looked as though the state would remain weddingless.

But love found a way. A moth-eaten statute was dug up which permits contract marriages. Now nuptial-minded Montanans merely file a joint statement with a court clerk, promising that they will "love, honor, and obey." And, quick as an official stamp can be applied to the document, they're man and wife.

As a result, people are now flocking to Montana from neighboring states and from Canada to get marriage contracts. Diseased or clean, they may wed freely. The state that tried to do a medical job without medical advice is worse off than it has ever been.

*Notably Alabama, Louisiana, North Carolina, North Dakota, Oregon, Texas, Wisconsin, and Wyoming.

*Expected to reduce the incidence of gin-inspired, hasty nuptials.

DIAGNOSIS AND TREATMENT OF ACCIDENTAL POISONING IN CHILDREN

JOHN AIKMAN, M D , *Rochester*

In 1930 I read a brief article¹ before this section on the incidence of strychnine poisoning in the United States. A more complete report was later published² in the *A.M.A. Journal*. Attention was here called to the menace to children brought about by the use of strychnine in bright-colored, sugar-coated cathartic and tonic tablets which are commonly purchased by the laity and frequently left within reach of the runabout child. It was pointed out that one-third of the deaths from accidental poisoning in children under five years of age were brought about by strychnine. Since then there appears to have been a reduction in deaths from strychnine but accidental poisoning still produces many unnecessary deaths. The problem of the management of these accidents is brought about by the multitude of articles that may be taken by children about the home and farm, also by the ever-increasing number of new drugs and poisons that are constantly being introduced. The subject of poisoning and its treatment dates back to earliest time, but modern chemistry has added to the problem more than to its solution.

The direct experience of any physician in the management of poisoning in children is limited, and the advice to be found in text books proves useless when some new and heretofore unknown poisoning is encountered. Our knowledge of modern chemistry and toxicology is also limited, especially after a few years out of college. While one will occasionally see groups of one type of poisoning, the cases are likely to be scattered.

Through the advice and encouragement of Dr. Joseph Brennemann³ the writer has attempted elsewhere to list the poisons that may be taken, the outstanding symptoms and such treatment as has been found of value. Repeatedly, poisoning occurs from articles that we have not considered and reports of such cases will be appreciated. All new and

unusual forms of accidental poisoning should be reported in medical literature.

The incidence of accidental poisoning in small children as well as the wide range of poisons that may be taken about the home and farm has already been presented,⁴ but very little was said about diagnosis and treatment and it is this phase of the subject that we will here consider.

We know that mortality rates do not show the true incidence of accidental poisoning because simple and non-fatal cases of poisoning frequently occur in the practice of physicians. While it is impossible to estimate the number of cases of poisoning that are never suspected or detected, the number must be very high. This is especially true in severe acute illness or in cases of sudden death. Zangger⁵ quoted by Pfandler and Schlossman states that only twenty per cent of poisonings are recognized. The other eighty per cent are either missed entirely or recognized too late for treatment.

As most of the children are too young or too frightened to give correct histories the most important item in the history is missing, and unless the physician has acute poisoning in mind the illness or death goes down unexplained or is covered by a blanket diagnosis such as acute gastroenteritis or bronchopneumonia—and the truth is never known.

With a history of the accidental ingestion of poison, the diagnosis is ready made and treatment is the only problem. Sometimes even the parents fail to remember or to be impressed with the fact that the child has three hours before taken a number of pills intended for adults. This was shown in one of our cases of strychnine poisoning. Few poisons give a clear clinical picture. If the possibility of poisoning is kept in mind a solution may be found to very peculiar cases that are first considered as infections.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

CHART III—GONORRHEA WITH POSITIVE SMEARS AND OTHER INFECTIONS (16 CASES)

CHART IV—NO GONORRHEA BUT OTHER INFECTIONS (22 CASES)

average of 2 cm of reaction forty-eight hours after injection

The question arises as to whether or not other infections might not intensify the reaction in cases infected with gonorrhea. Such was not the case as Chart III will show.

Chart III includes sixteen cases having gonorrhea with positive smears and with other infections present at the time of the test. Among these infections were the following:

Six cases of syphilis, four injuries with infected wounds, two incised abscesses, two chancroids of penis, and two carious teeth and chronic tonsillitis.

In this chart all of the sixteen cases show an average of 2.32 cm of reaction forty-eight hours after injection which compares favorably to Chart I.

The possibility of other infections having an influence on the value of this test as a diagnostic procedure was immediately suggested, but Chart IV shows that there is no apparent influence from other infections when a gonorrheal infection is absent.

This chart includes twenty-two cases never infected with gonorrhea but having other infections at the time of the test. An occasional case has more than one diagnosis, as follows:

Five cases of acute bronchitis, three acute appendicitis, five fractures, four syphilis, one phlebitis, one carcinoma of the stomach, one corneal ulcer, three acute tonsillitis, one peritonitis, two osteomyelitis, and two peptic ulcers.

In this chart fourteen per cent of the 22 cases show an average of .07 cm of reaction forty-eight hours after injection.

Conclusions

Gonococcus filtrate (Corbus-Ferry) has a definite value as a skin sensitization test for gonorrhea.

It is not particularly influenced by the presence or absence of other infections.

In this series of cases there were no false positive nor false negative tests.

300 W 54 St

hair and while this was being removed in the accident room, he suddenly lost consciousness. The interns were at loss for diagnosis until the matter was cleared by the chief resident physician who recognized poisoning from carbon tetrachloride used as a solvent for the tar. Carbon tetrachloride is used in industry as a solvent for gums, resins, and fats, in cleaning solutions such as "carbona," and also for dry cleaning. "Tetra" is sometimes used for drying hair after shampooing. It is employed as a fire extinguisher under the name Pyrene. Carbon tetrachloride is of value in the treatment of hookworm infection. When inhaled it produces irritation of the mucous membranes and bronchopneumonia has followed. It is both a circulatory and respiratory depressant. It will produce anesthesia and is twice as toxic as chloroform. Severe poisoning has resulted when exposure to the fumes has occurred in dry cleaning, and its use as a fire extinguisher especially in unventilated places has caused serious results. Very marked liver degeneration occurs in severe poisoning.

Intoxication from alcoholic beverages may occur in children even to the point of coma. Gasoline or its vapors may produce nausea, inebriation, coma, convulsions, cyanosis, and death. The odor of alcohol or gasoline assist here in diagnosis. Barbituric acid derivatives have a widespread use in self-medication and may be accidentally taken by children leading to unexplained unconsciousness, the same may be said regarding other sedatives and of derivatives of opium.

While convulsions are characteristic of strychnine poisoning, overwhelming amounts of other poisonous agents will also produce convulsions. Pyrethrum, sodium fluoride, arsenic, camphor, gasoline, kerosene, volatile oils, poisonous plants, and innumerable drugs have caused convulsions. While we were suspicious of poisoning in one case of strychnine poisoning, it was not until the mother finally recalled that her child had three hours before eaten cathartic tablets that we knew definitely with what we were dealing. The convulsions were not characteristic enough to make differential diagnosis from severe toxic convulsions accompanying gastroenteritis,

pneumonia, etc. In the typical case of strychnine poisoning from eating cathartic tablets, belladonna is also present and may produce a high temperature, as in one of our cases, to still more confuse the picture. After seeing such cases one wonders how many cases of unexplained deaths from convulsions may have been due to similar poisoning.

Children unconscious or in convulsions give no histories, and likewise, histories from frightened children between one and three years are unreliable. Older children guilty of misdeeds are apt to avoid rather than assist you to the truth. All of these may throw us from the right track.

Cyanosis is always an alarming symptom to both parents and physicians. When it appears suddenly and unexplained in children who have previously been well, poisons must always be suspected. The methemoglobin cyanosis produced by acetanilid and phenacetin has been recognized for years, but we are less familiar with the same type of cyanosis produced by many of the benzene derivatives which are widely used as solvents for gums, resins, fats, shoe dyes, and other dyes. They are used in cement for shoes, for auto top dressings, shellacs, varnishes, quick drying paints, rubber cement, stains, and dyes.

In April 1935 a girl of four years of age living near Kodak Park was seen to be very cyanotic. On examination I suggested poisoning from some benzene product. The father and mother were both chemists and assisted in searching for the cause. The mother had noticed a strong odor about the home but thought that it was from some chemical being used at Kodak Park. A coat that the child had been wearing was brought in. The coat and especially one sleeve gave a strong chemical odor. For a time we thought that the poison had come from a bottle of shoe dye remover that a neighbor had thrown in an ash can. Some time after the child recovered, the father discovered that a small bottle of anilin had been spilled in his chemical cabinet and decided that the child had here obtained the poison.

Two interesting types of poisoning with cyanosis have been noticed in children. *Laundry marks* on diapers have caused anilin poisoning when these diapers have been placed on the skin. Thirteen out of thirty-two infants in one

Neal⁶ recently reported three fatal cases of thallium poisoning that were at first diagnosed as encephalitis following chicken pox. The diagnosis was confirmed by spectroscopic examinations.

I am sure that one fatal case that I diagnosed as gastroenteritis several years ago was in truth arsenic poisoning due to a small child eating rat poison placed in the garage. Examination of the vomitus would have saved a great deal of trouble. Arsenic is found in various rodenticides, paint, fireworks, fruit sprays, and is quite widely used in medicine. The symptoms occur from one half to one hour after ingestion of the poison and can easily be mistaken for gastroenteritis or so-called cholera infantum. Stomach contents, stools, and urine should be examined for the drug. Phosphorus which is also used in rat poisons and fireworks will give gastrointestinal symptoms two or three days after the poison is taken.

Sodium fluoride as used in various insect powders produces severe gastrointestinal symptoms. In unexplained puzzling diarrheas occurring in runabout children living in the country, mushroom poisoning must be considered, especially that due to the *amanita muscaria* or "fly amanita" or the ingestion of poisonous plants. Cathartics eaten by children may also produce severe and even fatal diarrhea. Wholesale poisoning by infected food is easily detected by the group character of the accident. Nicotine widely used as an insecticide in gardens and green houses, said to be found in "Nico Fume liquid" and "Black Leaf 40" will produce gastrointestinal symptoms, but it also produces dyspnea, collapse, and coma.

In sudden and overwhelming collapse poisons must be considered. One of my patients went into sudden collapse and nearly died in his father's camp from eating some poisonous plant. Prompt lavage by a physician also on vacation nearby, saved the child. As in so many of these cases, they were unable to obtain an accurate history from the small child and no chemist or botanist was available to assist in the diagnosis. Cases of sudden cyanide poisoning in children have been reported from Western states. These children have crawled under tent-like

coverings where hydrocyanic gas was being developed to kill tree insects. In cases of collapse and convulsions, one must remember that some drug may have been taken hours before and the symptoms delayed due to the nature of the poison or to hard insoluble pills.

When sudden loss of consciousness occurs poisoning must always be considered. A fourteen year old girl and three younger brothers, in an unconscious state, were recently brought to the Genesee Hospital at eleven P M from a neighboring town. Another child aged seven was found drowned in a bathtub of water with the older girl hanging over the side of the tub. The officers believed that the girl had, in a fit of temper, poisoned the whole family. To complicate matters a small amount of arsenic was reported in some of the gastric contents obtained from one of the children. The officers and newspaper men were too anxious to make a crime out of the matter. However it was fairly obvious that arsenic was not the answer. It was pointed out that a hasty diagnosis might result in embarrassment of physicians and officers and in possible grave injustice to the girl. As the parents ran a green house, nicotine was considered. Carbon monoxide was suspected, but without a complete history could not be diagnosed. On return to consciousness the fourteen year old girl gave a clear story of having noticed fumes from a leaking stove and confirmed our suspicions of carbon monoxide poisoning. Looking back the diagnosis seems easy. The cases were not typical and the history was one of poisoning with intent to kill. No one had noticed or reported any gas in the house. Spectroscopic examination of the blood would have been a great aid in diagnosis.

When patients are found in closed garages with running automobiles or in rooms filled with charcoal fumes, a diagnosis of carbon monoxide poisoning is easy. The case stated and similar interesting cases prove that carbon monoxide poisoning may cause a serious diagnostic problem.

A peculiar case of unconsciousness occurred in another hospital. A boy had been admitted with a scalp injury. A large amount of tar was found in his

minations of bone are of assistance in lead poisoning

In making a differential diagnosis great assistance may be secured from chemical and biological examinations of the vomitus, blood, and urine. The spectroscopic examination of the blood will detect methemoglobin, and carbon monoxide hemoglobin. Thallium and other poisons may also be so detected by the spectroscopic examination.

Treatment prophylaxis Therapeutic accidents can best be avoided by writing and then carefully reading all orders for drugs. This includes orders on charts, in order books or on prescriptions to be filled by the pharmacist. All directions for parents or nurses in the home should be written and explained with even greater care. Dangerous drugs should be approached by smaller than the desired dosage until the susceptibility and tolerance have been tested. If dangerous drugs like bichloride of mercury are to be used, only the amount necessary should be ordered. Bichloride and other poisons are a menace on the medicine shelf.

Medicines should be kept well out of the reach of children. Drugs should be covered or well-corked. Left-over medicines should be thrown away and parents should be advised against keeping dangerous drugs in the medicine closet. Drugs such as bichloride of mercury, phenol, etc., should be distinctly marked "poison." Bright-colored sugar coatings are dangerous on any tablets containing poisons as they are so frequently mistaken for candy by children. This is especially true of cathartic tablets such as Hinkel's cascara, A B S, or A B S and C pills. They cause more fatal accidents in infants than any other poisons.

As has been stated the majority of accidental poisonings occur in small children just able to run about. The general tendency to put all things in the mouth and to mistake poisons for food or candy lead to these casualties. Nearly all such occurrences are due to carelessness on the part of some adult. General education of the public would prevent a portion of these, but the human factor must always be considered when poisons are kept about the home or farm. Rigid laws requiring the proper labeling of all poisonous articles, marking them as Poisons,

is the best safeguard. Dangerous poisons should never be used when non-poisonous articles will accomplish the same result.

Active treatment Active thorough treatment should be started at once, parents should be advised over the telephone regarding emetics such as powdered mustard in warm water to be given before you reach the case. Removal to the hospital is often of great advantage. Lavage by stomach tube or catheter should be thorough and repeated. Caution must be observed in poisoning with acids and alkalis also with children in convulsions. We have seen one child die in convulsions as the tube was being passed. Today the immediate intravenous use of luminal sodium, amytal sodium or other soluble barbiturates might prevent such a death. Advice regarding treatment for some new poison may be difficult to obtain. Latest advice regarding more common poisons should be available for immediate use, especially in hospital emergency departments. Mimeographed outlines like that prepared by Hanzlik¹² for the San Francisco Department of Health gives such instruction. Such an outline can be easily replaced or changed when necessary.

The administration of solutions containing sodium bicarbonate, potassium permanganate or animal charcoal may be of assistance and can do little harm. In poisoning with heavy metals, sodium thio-sulphate (U.S.P. sodium hyposulphate) commonly known in photography as "hypo", one to ten gm in water may be safely used.

Man has always sought for and believed in antidotes, but such agents are mostly of questionable value when overwhelming amounts of poison have been taken. Recent conflicting reports regarding the value of methylene blue in carbon monoxide and cyanide poisoning and in the use of sodium formaldehyde sulphoxylate in mercury poisoning are confusing. In any case of poisoning the amount taken, the susceptibility of the patient, and the amount of the poison absorbed before lavage must be considered when records are reported.

In profound poisoning artificial respiration, oxygen carbon dioxide inhalation and repeated transfusions must be kept in mind.

maternity nursery were so poisoned ⁷ all recovered *Black shoe dye*⁸ containing either nitrobenzene or anilin has produced poisoning in older children when shoes recently dyed black have been worn for a few hours. It seems only necessary for the fumes to come in contact with the skin. The marked general cyanosis that occurs due to the formation of methemoglobinemia is very alarming until the cause is found. Infants are apathetic, gasp for air, and may develop collapse and even convulsions. Headache, chills, general weakness, vertigo, somnolence, nausea, and even stupor occur in older children, and even death has been reported. Recovery, however, is the rule. Poisoning has resulted when nitrobenzene has been given by mistake instead of oil of bitter almonds. Unfortunately nitrobenzene is sometimes called artificial oil of bitter almonds, thus causing confusion.

Benzene products as used in moth poisons also produce cyanosis. Such a case was seen by Dr Marion Morse of Endicott, N Y.⁹ A child after eating parachloronitrobenzene became severely prostrated and cyanotic. This product is sold without warning as to danger and information regarding treatment was not available. Repeated transfusions were given but the cyanosis due to methemoglobin lasted several days before recovery. Oxygen was also administered. Moth preventatives of this type are widely used. Cyanosis due to nitrite poisoning may sometimes occur after the administration of bismuth subnitrate.

A chapter could be devoted to the skin rashes produced by drugs. As these usually occur from medication the diagnosis is not difficult. However, we have all seen erythema, dermatitis, and other conditions that were very confusing until an idiosyncrasy to drugs being administered was discovered. Atropine, barbituric acid derivatives, salicylates, bromides, phenolphthalein, and other drugs frequently cause embarrassment.

Atropine in itself is annoying in other ways, as it is widely used in the treatment of children, and mild cases of poisoning frequently occur. The flushed skin, fever, rapid pulse, dilated pupil, and dryness of the throat quickly pass if the drug is discontinued. Very high tem-

peratures may occur, as high as 106°F in one case. We have seen extreme abdominal distension, very rapid respirations, and marked discomfort in small or newly born children who have received too much atropine. We also saw seven fairly severe cases of poisoning in school children who had been poisoned by atropine prescribed by mistake for homatropine for use in the eyes. They had mild delirium, and all recovered. Within the last year a child was seen for sudden and unexplained dilatation of one pupil. Use of atropine was denied. An ophthalmologist was so certain that atropine had been used that the parents recalled that the child had handled a cork from a bottle containing some medicine for vomiting. This medicine was atropine. Atropine poisoning may occur in dispensary practice when the drug is ordered in both the pediatric and eye clinics. Poisoning may result from cathartic tablets when atropine or belladonna are combined with strychnine as in A B S, or Hinkle's pills. The berries of deadly nightshade may produce serious poisoning.

The development of respiratory symptoms may sometimes be traced to inhalation of powders such as zinc stearate or inhalation of strong acid fumes. Warning¹⁰ reported a high incidence of bronchitis and pneumonia in twenty-three cases of kerosene poisoning. Nose drops containing menthol have also produced respiratory symptoms such as choking, dyspnea, and cyanosis. Unexplained nephritis may be due to poisoning.

The improved methods for estimating the lead content of blood, urine, and hair reveals a much higher rate of lead poisoning than has previously been suspected.¹¹ The ultimate effects of small doses of lead result, we are told, in many obscure symptoms that are now being missed by the medical profession.

Various syndromes may be associated with "subchronic" lead poisoning. Symptoms are extremely variable and may stimulate mental disease, acute peritonitis, gall-bladder disease, and renal colic. Early symptoms are anorexia, nausea, weariness, constipation, headache, eye-symptoms, and circulatory manifestations. Careful laboratory examinations for lead poisoning should always be considered in the study of obscure cases. X-ray exa-

AN OLD REMEDY BOOK

LOUIS J BRAGMAN, M D, *Binghamton*

Practicing in the country town of Elbridge, N Y, one hundred years ago was a doctor by the name of David Wilson On February 11, 1834 he turned to the first page of a notebook he had just purchased, and began a series of entries The first notation is of a remedy for cough in tuberculosis, the last, in 1859, is a formula for the preparation of pickled ham! A survey of some of the items listed in this remedy book gives a cross-section of the pharmacopeia in use a century ago in central New York.

For consumption, take a piece of double refined loaf sugar as large as a walnut, drop one drop of spirits of turpentine [sic] upon it, and take it in the morning fasting Increase one drop every morning till nine mornings if the stomach will bear it, then skip nine mornings Commence again and take it as the stomach will bear, every day till the cough abates

For cough, take maple liverwort—that which grows on soft maple. Steep it in vinegar or water, and sweeten with loaf sugar Dose as much as the stomach will bear

For jaundice, take hog's gall and steep it in spirits Dose one tablespoonful three times per day

For contracted sinews from rheumatism, take the marrow of a horse's bones and oint the patient with it and wrap him up in blankets

For swellings and inflammation from wounds or bruises, take chestnut tree leaves and sweetapple tree leaves and boil or steep them strong in water, then apply them to the parts affected as warm as the patient bears, also wash the parts with the tea warm Continue to apply the leaves hot and rub the part with the tea till the swelling and inflammation abate, then dress the wound with simple salve or ointment.

For diarrhea, take common puff balls and stew them in fresh butter or beat them up with eggs and bake them, or steep them in water or brandy

Two cancer cures are listed take balm of gilead leaves, beat them fine and apply them as a poultice, or take mutton suet, add to it one teaspoonful of the filings of pure brass, apply the mixture as a plaster to the sore, and keep it on till it heals To the latter prescription a notation is added *This has never failed*

A prescription for scalds and burns which was borrowed from one Dr Little is prepared as follows Take one lb of lard, one ounce of sulphur, one tablespoonful of tar, one teaspoonful of pulverized verdigris, and mix them well together cold. Apply the ointment to the burn with a feather and do not wrap it up with clothes or bandages

To make castor oil palatable for children, take the quantity you wish to give, boil this a few minutes with the same quantity of milk, then sweeten with a little sugar and stir

For swollen breasts, take one lb of rosin, one-half lb of bee's wax, one-quarter lb of mutton tallow, one tablespoonful of black pepper Melt these together without burning When melted pour into cold water, then work it into equal parts of British oil, turpentine, and spirits of camphor

A diebetic [sic] pill is compounded as follows Phosphate ferri, one dram, pulv aloes, twenty grains, gum arabic, q s Make into twenty pills Dose 1—3 times per day

For a fever sore he recommended crocus martis, two ounces, sulphas zinc, one ounce, in two quarts of rain water The following was efficacious in dyspepsia sulphate soda (Glauber salts), six ounces, epsom salts, eight ounces Dry them in an oven till the water of crystalization is entirely evaporated, then powder finely with two ounces of carbonate magnesia, and keep stopped closely Of this, one teaspoonful was dissolved in water and taken in a gill of lemonade two or three times daily

The prescription of Dr Reese for cholera was used by Dr Wilson It contained sulph. ether and compound spts of lavender, of each one ounce, tinc of opium, two drams, oil of cloves, ten drops Dosage one teaspoonful for an adult, for children in proportion To be repeated as often as necessary

A vermifuge was comprised of castor oil, eight ounces, wormseed oil, one and one-half ounces, spts turpentine, two drams, carbonate soda, one-half drams Dose one teaspoonful once an hour

A formidable formula for a panacea contained no less than twelve ingredients

Tincture of opium, one gill
Liquorice, dissolved, six gills
Tincture of anise seed, one gill
Tincture of camphor, one gill
Tincture of elicompani, one gill
Solution of sal tartar, one-half gill

Discussion

DR FRANK VAN DER BOGERT, *Schenectady*

—It is difficult to add anything to so complete a study of poisoning as that which Dr Aikman has made. His paper, however, contains several suggestions, the value of which may well be emphasized.

The importance of the proper labeling of poisons cannot be overstressed. I learned my lesson years ago before I became a "compleat" pediatrician. An adult to whom I had given a $7\frac{1}{2}$ gr tablet of bichloride of mercury, dissolved it and drank most of the solution. It had been carefully labeled as poison with the directions to use externally and I am willing to admit that my first act upon learning of the accident was to secure, for evidence, the properly labeled envelope. Fortunately the solution had been taken immediately before a breakfast of four eggs which if undercooked may have had something to do with the favorable outcome.

Drugs to be valuable in treatment must be potent and probably all of us in practice frequently prescribe those which if taken in overdose might prove dangerous, hence it has been my custom to carry with me on my daily rounds labels to be attached to every glass or bottle left with a patient. Such a procedure may occasionally cause suspicion but the drinking of a glass of clear solution mistaken for water has occasionally occurred. The warning may read "Dangerous in overdose" rather than "Poison."

Dr Aikman calls attention to the danger inherent in the sugar-coated pill and preparations designed to simulate candy. While writing this, I received a telephone message that one of my patients had eaten a number of sweet and flavored calomel tablets left for her brother and which she had heard me inadvertently call candy. She needed them but I confess guilt of the methods I criticize. Attractive and palatable liquids may be as dangerous. We have records at the Ellis

Hospital of poisoning due to cheracol and oil of wintergreen.

In my opinion palatability should not be considered in connection with medication even in the child. From early life, children should be made to realize that the bad must be accepted with the good. With the right attitude upon the part of the parent or nurse bitter medicine is as readily taken as sweet. I have never found any difficulty in giving castor oil without orange juice. An appetite for medicine should not be encouraged, nor can unpleasant taste be depended upon as a safeguard. It is astounding what children will eat and drink. I have known a little youngster to eat a cake of bluing and I have had a patient whose mother could not send her to the drug store for castor oil because she would drink it before she got back. Some children are said to love castor oil. We have a hospital record of the death of a child of $5\frac{1}{2}$ years after drinking the greater part of a pint of whiskey and some anisette. This means that dangerous preparations, whether camouflaged or not, should be kept out of reach of children and to do so, the cooperation of the family physician may be required.

The difficulty of obtaining satisfactory histories in children has been discussed. It must be realized, however, that the fact that the problem is put up to the physician is sufficient evidence of the possibility of danger and justification for lavage at least. Failure to institute treatment because of uncertainty may be fatal. I have had such an experience a child seen by another physician who was apparently not impressed with the story, died in convulsions five hours after he was first seen. He had evidently, as the mother feared, swallowed some of the sugar-coated pills containing strychnine against which Dr Aikman has warned. Even if the preparation may be not known to be dangerous the psychology of a stomach washing may be a warning not to repeat the procedure.

A Utica paper recently by a slight slip printed the intriguing news that "plans for the year will be made by the material welfare committee of New York State Medical

Society here tomorrow."

If the State Society ever has a "material welfare committee," many will wish them quick action and good luck.

scorn. There were endless quarrels "He was a lazy, incapable, good-for-nothing person, who should not have married if he could not feed his three children and should not have taken a girl away from a decent home where she had plenty of better opportunities"—All the good, comfortable years were forgotten.

The children, who used to be chummy with him, were taught to shun their father and to laugh at him. They were left more and more with their grandmother while mother disappeared from the house for several hours daily and later nightly.

Patient did his best to find a job, but to do that was difficult and when he did land one—he became a clerk in a dry goods store—it was too late for his rehabilitation. Wife, children and mother-in-law had disappeared. He knew who had replaced him, but could never find out where they had all gone. What were his complaints?

"Nervousness, shaking, aches in various places, impossible to concentrate, crying without any reason, unable to work."

"The boss sends me away, saying I am too nervous. Doctor, I cannot go on like this. Something must happen. I keep on thinking, Where are my children? Why can't I be with them?" he said with an expression of infinite sadness.

His physiognomy was that of the typical hypochondriac.

For four years he had not gone to a

movie, had not read a newspaper, had seen but few friends and at rare intervals.

He was convinced that he was suffering from some physical disease, although all the physicians—general practitioners—under whose care he had been had told him there was nothing the matter with him. Examination, indeed, showed no evidence of organic pathology. Basal metabolism, upon which he insisted, was also normal.

Sexual intercourse? Yes, he had had it two or three times, but it was due to the urge of a woman, an old acquaintance from his boyhood days, now a widow, who wanted to live with him. He could not make up his mind and was rather cool to her proposal.

Consolation was out of the question. Nor would it have been fair, he was entitled to his sorrow.

However, there was the remedy. His boyhood love or semi-sweetheart.

Encouragement in that direction, assurance about his somatic normality, and rationalizing talks with a view of giving him a new philosophy of life and changing his viewpoint as to what was really worth while, gradually improved his condition. Teaching him to relax from his tenseness was successful and helpful. To be sure, he was not cured, but he could smile again and live with his new woman who accepted him as he was, and work. He ceased complaining.

Down and Out

A man of forty, married and having two children and living with his family. He was seen at the height—or depth—of the economic crisis, around 1932, when even home relief did not exist or was difficult to get.

He had been strong and healthy until a few months before, when the last of his savings had gone. He had had several occupations. Originally a coal miner, then a labor leader, at the head of his local in the trade union. Later he was an office worker and had some other jobs which I have forgotten. Recently he had been drifting, trying to make a living, but failing. Finally he was peddling various objects on ships, attempting to sell them to sailors.

He had studied in a well-known labor college and used to be very sociable.

But now, he was uninterested in anything, brooding the whole day, sitting in the house, without the least will power. He was not even able to worry, although "rent" seemed to have remained a deterrent, as at its mention, he would become panicky with fear.

He came with his wife. When asked what seemed to ail him he said his legs were weak, he had lost weight and mentioned a number of incoherent complaints. But she gave better information. He could not sleep, didn't care about anything, was "nervous," sad, refused to eat, or to go out, or to see friends. Since she had found some odd jobs for herself the situation was somewhat less desperate. But he could not attend to the children, therefore she didn't dare to leave the house. Moreover, she was afraid he might do some harm to himself.

Bad as the condition seemed in this case, the success of the treatment, consisting of conversations, was surprisingly rapid. The patient, stunned and humiliated by his inability to earn a living began to trust and believe the doctor, regained confidence in himself, which enabled him to renew his old connection and look for work. While this did not solve his problem entirely, as his first earnings were scant, it was a good start. He has been well ever since.

Tincture of balsam tolu, one gill
Loaf sugar, six ounces
Water of horehound, one pint
Emetic tartar, two scruples
Tincture Bloodroot, one gill
Tincture of myrrh, one gill

Mix the whole together and it will be fit for use. Dose for an adult, from $\frac{1}{2}$ to one teaspoonful $\frac{1}{2}$ hour before meals

Other formulae were for physic pills, colic pills, piles, tonics, bitters, itch ointment, dentrifice, and cold wash Intermingled

also with veterinarian remedies were assorted directions for the preparation of white paint, mead, cream soda drink, and beer He listed a decoction to destroy bed-bugs, and a formula for a laundry powder, and he concluded with the aforementioned method of pickling ham The remedy book of Doctor Wilson shows him to have been a family physician in more than the usual sense.

43 MAIN ST

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, D R P H, New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

A Little Genius

A mother brought her little boy of four because he was "nervous," full of temper, restless in his sleep

He was a very slim and extremely vivid child I had seen him once at his home, ill with some children's disease, in a dark room in the rear of a house, the door opening on a stoop in a narrow courtyard I remonstrated with his mother for living in such rooms, which were bad for the entire family, but especially for the child At that time she explained that, in a decent neighborhood, that was all she could get for the low rent she was able to pay However, as she told me later, my threats of future calamities had had effect and she had moved away to better quarters, although in a poorer section

But this time the child was tortured in another way This mother had great ambitions for him, her only one She had heard about the famous violinists who had begun to study in their childhood and she was sure that he too would achieve success if he started early So he took lessons and she saw to it that he practiced for long hours daily Even to our consultation she carried his violin, as they were both coming from the appointment with the teacher

The boy had but little leisure and rarely played in a childish way, except with his mother She claimed that the other children would spoil him, would drag him down from the high pedestal upon which she had placed him As if that was not enough, she had obtained for him an engagement on the radio where he would recite once weekly and would be paid five dollars The mother coached him the whole week and made him speak sentences and words which he did not understand

There was great danger both for the mental and the physical condition of this child The most eloquent language of which I was capable could do no justice to the seriousness of the situation. But my talk was inadequate and unconvincing, at least to this mother She continued to work her child until worse symptoms developed

His fits of anger were more frequent and lasted longer He refused to eat even those foods of which he used to be fond

Then only the mother gave up her plans and freed the child As soon as he was allowed to play with other youngsters and had none of his former worries, he began to improve. Within a few weeks he was cured

Humiliation

This is a simple story of a man who was unhappy because he had been humiliated from many sides It was more than an ordinary inferiority complex. It was a high degree or rather a bad form of maladjustment which began with his misfortunes Possibly some psychiatrists might discount the events in his life as of minor importance or as contributing factors only, in the causation of his mental troubles That he

always had a tendency to hypomania is indubitably true But from all the information that could be gathered he apparently went along smoothly until four years ago when the following things happened

He lost money and with it his business and his dominant position in the family

His wife, for a long time enticed by her mother, who "hated" our patient, now finally dared to throw at him all her accumulated

research and study goes to Drs Kimball and Gudakunst, but without an intelligent physician in the key position of the Detroit Board of Education this work would have been impossible.

We congratulate the city of Detroit on the wisdom which selected a man of Dr Burt R Shurly's standing and attainments to be at its educational headquarters. Were more such men in key positions their influence and guidance might make more acceptable the proposals of sociologists generally.

An Invaluable Precedent

Medicine is not alone in welcoming the outcome of the State's action against the Life Extension Institute in New York City. By upholding the statutory ban on the practice of medicine by corporations, however well-intentioned, the decision strengthens similar prohibitions in other professions. Interdiction of physical examinations by the Institute, even though unattended by treatment, shows that it is not necessary to perform all the acts pertaining to a profession in order to come within the meaning of the law, performance of a single professional act constitutes professional practice.

The precedent set in this particular case will go far to maintain the integration of all professions and individual responsibility therein. In law, as in medicine, private practice has suffered greatly from corporate encroachment. Title companies, government agencies, have taken over many lucrative branches of the law, with the result that qualified members of the bar are denied the economic opportunity that should be theirs. This destruction of the normal incentives stifles initiative, inhibits the constant striving for self-improvement which is essential to high professional standards, and drives many with the requisite mental and moral qualities into more lucrative pursuits. What is true of the law in this respect is equally applicable to medicine, dentistry, and other professions.

It is not to be assumed that the decision

in the Life Extension Institute case will operate solely to the profession's advantage. There is nothing in the service rendered by such corporations that cannot be done at least equally well by the private practitioner, either at his office or, in complicated cases, in the hospital. As a matter of fact, it is universally conceded that the health examination has the best chance of eliciting significant data when it is performed by the family doctor, who is familiar with the patient's heredity, past medical history, and social and economic environment.

Discussion of this case is incomplete without a word of praise for the fair attitude maintained throughout by Referee John Caldwell Myers, Deputy Attorney General Ullman, and the attorneys for the Life Extension Institute. In an action to uphold basic provisions of the medical practice laws, they have displayed a high degree of legal conscience and public spirit.

A Formidable Enemy

Rises in the mortality from diphtheria warn the profession that this dragon of childhood is momentarily subdued but not conquered. When immunization is pressed diphtheria morbidity rates drop—under favorable conditions actually to zero. As soon as vigilance is relaxed, its incidence increases.

Physicians should not wait for health departments and welfare agencies to launch periodic drives for diphtheria immunization. It is the contention of organized medicine that every practitioner is a health officer, at all times fighting in the front lines. It should not require spectacular campaigns to persuade him to take the offensive against a preventable disease. Every medical man should consider himself responsible for all the children in all the families in his care. He should suggest inoculation at the proper time, and, if parents hold back, explain the rationale of prophylaxis and the danger inherent in its omission.

A Doctor's Influence on an Educational Problem

It has always been our contention that when sociology and medicine meet, that medicine necessarily must take the leading role. Our antagonisms to propositions and schemes embracing medical problems advocated by other than those with a medical background and training were never aroused because they were proposed by nonmedical men, as by the fact that they demonstrated so little knowledge of the medical viewpoint. Therefore we are wont to advocate not only the integration of medical opinion in all these schemes, but actually to agitate for the leadership of medical men in them.

A case in point is that of Dr Burt R Shurly of Detroit. He is no politician, nor office seeker. He is a very eminent physician who has had signal honors paid him by professional and academic societies. Knowing the needs, and anxious to help, he accepted a position on the Board of Education of Detroit. Today, in the published announcement of the results of a study on educational and therapeutical aspects of epilepsy among school children, by Drs Kimball and Gudakunst,¹ the work of a good medical man on a sociologic problem again finds justification.

Briefly, Shurly made it possible to collect all the epileptic children of school age in one central school. They were collected at their homes and returned to them. They were intensely studied while in the special school, and the factors of heredity closely elicited. They were subjected to a treatment based on the suggestions of Choroschko of the Metchnikoff Institute which consisted of daily intramuscular injections of two c.c of a ten per cent concentration in liquid form of lipoids from sheep brain, prepared for this work by the Parke, Davis and Company laboratories. The results were gratifying. Of one hundred and six so treated, 123 per cent were apparently cured, 50.9 per cent were definitely improved, and in 36.8 per cent no improvement was noted. Another fact was ascertained. For the six months that forty or more boys were kept together at school, they had sixty per cent fewer seizures per day at school than they formerly had had at home. Similar results were observed among a group of girls. It seems that for the majority of them, they are physically better off in school than at home, and it was possible to develop a special plan of education for them because the very nature of their disease prevents them from utilizing ordinary methods of education.

Of course, the credit for the painstaking

¹ Kimball, O. P. and Gudakunst, D. D. A Study of Epilepsy in Detroit, *Jour. Michigan State Med Soc.* p 641, October 1936

liquid petrolatum is absorbed and is stored in the liver where it produces a fatty infiltration¹ In addition, the continued ingestion of the oil tends to deplete the organism of fat-soluble vitamins

What bearing this has upon psoriasis is problematic Yet people suffering from this type of dermatological lesion have been known to exhibit pustular eruptions whose exudate was of oily consistency These patients all told of having taken large quantities of liquid petrolatum What is of added significance is that studies of the involution of psoriatic lesions have established the value of demineralization in the treatment of this disease

Final judgment cannot be passed concerning the relationship of psoriasis and liquid petrolatum The attention of the profession is directed to the published reports and to a reconsideration of the broader problem of the inertness of this drug

CURRENT COMMENT

"*LORD HORDER OPENED the discussion on the subject, 'The Strain of Modern Civilization,' before a large audience in the section of physiology of the annual meeting of the British Association for the Advancement of Science. He said that from the early days of the primitive curse life had always imposed a strain on mankind. That was the penalty we paid for living at all. There was, however, implicit in the title of the discussion the suggestion that the stress of modern life had new elements and was excessive. * * * Behind the screen of headache, indigestion and fatigue inquiry revealed the anxiety factor. In the sphere of microbic diseases we had new diseases for old. There was an increase of those more subtle germ diseases called 'subinfections,' in which the virulence of the microbe was low while the susceptibility of the host was high. In many of these the germ came from within and not from without.*

"As to the cause, it was almost platitudinous to speak of the anxiety connected with the competition of living and the equally grave sense of international insecurity, of the pace at which we lived and of the precariousness of life itself in the streets, so

that we seemed to live by accident rather than to die by it, of the monotony and drabness inherent in the long hours of physical and mental effort of many workers, of the exciting nature of our amusement, and of noise, needless, stupid, provocative. He would add another cause, more subtle but none the less recognizable, the slackening of the moral code in the sphere of increased freedom of both sexes

"* * * It is seldom that a physician makes a political pronouncement, and however eminent he might be, one from such a source would not receive much attention. However, what Lord Horder said has received widespread notice in the press. He saw little hope for the people through mass movements, whether Fascist or Communist. When individual freedom had been sacrificed he saw no chance of achieving that control in the spiritual sphere through which he believed salvation could come to the human race. What matter the color of men's shirts if these were soon to be their shrouds? 'A plague on both your blouses,' he said to the accompaniment of cheers. Concerning numbers, he was much more interested in the quality than the quantity of our people. When the clash came, if come it must, between two hordes of the new barbarians—civilized barbarians if they liked—it might well be that the salvaging of the world or its doom might depend on whether northern and western Europe and America had been able to preserve an individualized society or, like the two opposed masses in the dictator countries, had yielded to the tremendous pressure of what might prove to be a bastard civilization and had caught the infection of despair. If our own individualities refused to be tub-thumped or intimidated into a pulp, all might be well. * * * He could only state his faith in the individual and in the enormous potentialities of the human spirit. Was it not a handful of individuals who guided the vast experiment proceeding in the east of Europe, another handful that drilled humanity in the center, and one individual alone who balanced himself dramatically as on a tight rope before the breathless crowd of the South? If physicians had a political color, like lawyers, it must needs be Liberal. A rebirth of that spirit in British political life would be one of the best medicines that our strained lives could have administered to them."—From the regular London correspondent to the *Journal of the American Medical Association*, under date of September 19, 1936, in the October 31, issue of the *JAMA*

"No DOUBT you've heard it often—the argument intended to prove that state medi-

¹ Gaul, L. E. N. Y. STATE J. MED. 36 1219, 1936

This is a sphere of worthwhile, legitimate activity for the private practitioner, and one he cannot afford to neglect. For poor patients the immunizing serum is available without cost.

If physicians are apathetic about pressing immunization against diphtheria—a safe and proven prophylactic measure—they cannot complain if government agencies invade the field of disease prevention and make it their own. Once they are established there, the tempting domain of therapy is in plain view and easily reached.

The best way to avoid large scale state medicine is to keep to a minimum government health activities—preventive or therapeutic—involving actual ministrations by a physician to an individual. This can only be accomplished if the private practitioner recognizes his duty to wage an aggressive fight against preventable disease.

Induced Hypoglycemia as a Therapeutic Measure

In 1930, Sakel¹ reported on the use of insulin in connection with the treatment of morphine addicts. He noted that the hypoglycemic state, which developed despite the administration of carbohydrates, produced a quieting effect on the motor excitments observed during the withdrawal period. Upon extending this form of therapy to patients suffering from schizophrenic disorders a marked improvement was noticed following its use.

In general, the method of treatment consists of gradually increasing the stages of hypoglycemia until coma, and oftentimes epileptic seizures are induced. Needless to say, the patient must be hospitalized and scrutinously watched since this regime of treatment is not without danger. From the first phase, wherein increased salivation, twitchings, and profuse sweating are accompanied by a subjective sense of mental calm, the patient is brought into

the second or so-called "shock-phase." Here normal reflexes disappear, and the subject becomes comatose. Tachycardia, irregularities in respiration, and motor disturbances not unlike that of a decerebrated animal are evident. Convulsions of an epileptic nature often ensue. Following this phase, the administration of the shock-dose of insulin is lessened in frequency until schizophrenic and psychotic manifestations have disappeared.

Any hypothesis which at present can be advanced for the rationale of this therapy must be purely tentative. Glueck,¹ who states that eighty-five per cent of all "paranoid patients who had been ill less than six months recover their normal health" after repeatedly induced hypoglycemic states, feels that this is a type of cellular therapy which supplements the psychoanalytic treatment. The insulin shock puts the brain cells at rest and permits reparative processes to take place, while the pathological pathways are eliminated and the pre-psychotic tracts are regenerated. The role of the insulin-antagonists—the adrenal and pituitary—which are activated during the hypoglycemic state, may also play an important role.

Here is something to conjure with. It deserves extensive trial. Anything which holds out but a ray of hope for our charges suffering from what is now called functional insanity calls for a thorough investigation. It is even possible that other diseases may be found to respond to hypoglycemia induced by insulin.

Psoriasis and Liquid Petrolatum

No other drug has caught the popular fancy or become symbolic for "absolute safety" like mineral oil has during the past quarter of a century. Here, at last, was a "safe" cathartic because not only was it not absorbed by the body but it also was inert during its passage through the intestinal tract. From experimental data available, however, it seems that

A Correction

In the October 15 issue of the Journal (page 1570), an error occurred

A list of the members of the Committee of Economics was published with their addresses, telephone numbers, and assignments to certain sections of the state in case of advice that might be needed for benefit of the society

Instead of Dr Frederick Stephen, it should have read Dr Frederick S Wetherell

A Protagonist for Socialized Medicine Speaks

929 Marcy Avenue
Brooklyn

To the Editor

In your Oct. 15, 1936 issue appeared an article entitled "The Country Doctor" (p 1538) Everyone knows that the New York State Medical Journal is a vast propaganda machine against Socialized Medicine, yet this "Country Doctor" article is the best article why we should have "Socialized Medicine" It is the most illuminating article in favor of it. It tells the truth, whereas your "On the Witness Stand" by J W Walch is chock full of lies

Sincerely,

NAT KANNER, M.D.

P S Print this in your next issue I dare you!

DOCTORS DO NOT WANT SECURITY"

Newspapers around the State are quoting under prominent headlines the statement of Dr Floyd S Winslow, President of our State Society, that the doctors "do not want to be secure. We want to remain insecure." He made this striking declaration in his address at Ithaca on Sept. 17 before the meeting of the Sixth District Branch To quote in part

We need to be told these things over and over again. The advocates of socialized medicine lure the profession with the siren song of bureaucratic jobs, assured income—security—false security We do not want to be secure. We want to remain insecure. We want to continue to be required to give our very best to every patient, or lose out in the gentlemanly competition which exists within our ranks This is an incentive that operates to our insecurity, but to the security of the patient. We prefer the discipline of private practice which keeps us on our toes, to an assured income under bureaucratic control where our highest ambition is more likely to be to keep ourselves solid with the politicians who have taken over the job of running our profession.

I repeat, security for the doctor means insecurity for the patient

And it cannot be too emphatically put that it is incumbent upon us, by the pursuit of such measures as these, to prevent those whose occupation is to talk about medical care, from inaugurating visionary proposals tending to prevent us, whose occupation is to provide medical care from keeping faith with our patients and with the public. We have been accused of thinking only of our bank accounts when we oppose compulsory health insurance. When did we ever think in terms only of our bank accounts? Where is there another profession which is so impersonal in its primary objects, working so surely, and so effectually, fighting every kind of disease, driving out of existence, if it were possible to do so, the very source of our income?

Today the American public is the recipient of the best medical care in the world, and I need not bother you with the statistical evidence that with few exceptions, our death rates are below all those countries where the doctor's activities have been painfully made the object of the state's beneficence.

(The full address will appear in a later issue—Ed.)

DOCTORS GET BOOTLEG MONEY

Word by wireless to the New York Times tells of a police raid the other day on the Cafe Edison, headquarters of the American Medical Association in Vienna. The head waiter and other employees were arrested

for illegal dealings in dollar notes, which were being exchanged at prices showing a big discount on the official rate for the schilling. It was stated that more than 100,000 schillings were exchanged at this cafe.

cine is the only logical way out 'Look at our postal service,' you are urged, 'There's a successful example of state socialism!'

"Well, let's really have a look! Postmaster Farley has pointed with pride to a \$5,000,000 postal service surplus. It sounds impressive. The only trouble is that the postmaster achieved this statistical feat by deducting \$70,000,000 for subsidies and free mailing privileges and by reducing the quality of postal service.

"Socialization—whether of the post office or of medicine—always seems extremely profitable and worthwhile, unless you are one of those skeptics who just won't take a fellow's word for it!"—This from William Alan Richardson in the October issue of *Medical Economics*. The following bit is from the same pen "Amid all the ballyhoo about socializing medicine, we have yet to hear of a plan that will take the indigent out of the lap of the profession. This phase of the medical-care problem is assiduously avoided by our reformers.

"Granted that groups of physicians in certain cases have been able to obtain some compensation from local authorities for the care of the indigent, satisfactory arrangements of this kind are few and far between. Furthermore, the fees afforded by them are pitifully lean.

"Instead of focusing their entire attention on the 'neglected' middle-class patient, those who seek a change in the present order might better give some thought to the charity question. There's a stickler that needs an answer."

"THE SCARCITY OF PHYSICIANS in public affairs indicates that medical men almost more than any other body of men take no active interest in the affairs of the nation and its governmental subdivisions. To be sure, there are a few who are active in public affairs, but physicians should realize that before any constructive health legislation can become a law there should be medical men—real physicians—men who have practiced medicine and know the difference between health and the lack of health—acting in the capacity of advisors.

"* * * It is not suggested that all med-

ical men should suddenly be seized with public spirit, for that cannot even be hoped for * * * Still, there are physicians—many of them—for whom business, due to their success, has become a secondary issue. As human beings these men now feel the desire to relax and enjoy the fruit of their labor. However, we can pray that perhaps one of these men—perhaps two or three—might sacrifice a little of their well-earned leisure to the public weal. A few doctors who possess intelligence, spirit, courage, which attributes the laity has been taught to believe inherent in all medical men, could work wonders in public work. These men, by actively entering the field of public affairs, could live down the accusation that politics is a 'dirty game.' Obviously, a little constructive medical legislation would dispel the vapors of bungling legislation which is being enacted by many legislators who are ignorant of the work being done in medicine. The successful doctor is the logical person to do this job"—From the *St. Louis County Medical Society Bulletin* of October 23.

THE AMERICAN HOSPITAL is the subject of an editorial in *The New York Times* of October 23, from which we quote in part " * * * Mr. Winthrop Aldrich, at a gathering of the trustees of private hospitals in this city * * * put these institutions (the hospitals) among 'the most precious things in our American life'—precious because the noblest of human virtues has here a highest realization. If it 'frets the saints in heaven' to see how many desolate creatures on earth have 'learnt the simple dues of fellowship in a hospital,' how much rejoicing there must be over the conscious and voluntary giving to make such social comfort possible.

"There are positive reasons for maintaining private hospitals, their benefit blesses both those who receive and those who give. There are also reasons negatively holding against the transfer of these agencies of human fellowship to public support and administration, lest one of those human values which determine the high degree of civilization be diminished or lost."

ARTIFICIAL SYNTHESIS OF VITAMIN B1

Announcement is made by Dr. R. R. Williams, Chemical Director of the Bell Telephone Laboratories, and Dr. J. K. Cline of the Research Laboratories of Merck & Company of the artificial synthesis of vitamin B1. Other important collaborators in the work have been Professor H. T. Clarke, Dr. E. R. Buchman and Messrs. R. E. Waterman

and A. E. Ruehle. The earlier work was done at Columbia University and the later phases at the Research Laboratories of Merck & Company. This development marks the culmination of twenty-six years of intensive experimental effort by Dr. Williams on this the first of the vitamins to be discovered.

Historical Article*

A HISTORY OF MEDICINE IN THE STATE OF NEW YORK AND THE COUNTY OF MONROE

FLORENCE A COOKSLEY, B A , M A , Rochester
Librarian, Rochester Academy of Medicine

Part I Outline of History of Medicine in the State of New York

Chapter III

Repeal of the State Medical Laws

Recommended by Commissioner State Society opposed to entire repeal, Quacks allowed to practice Decline of County Societies Organization of independent Medical Societies, Change in practice of medicine, Progress of State Societies Break in State Society

Now we come to a great change in the medical affairs in the State, occurring in 1844. Some might consider this period as a Dark Age in the history of medicine in New York State, beginning with that year. This change was brought about by the inadequacy of the law to control quackery. While Monroe County did not initiate the feeling against State regulation of medicine, it did begin an investigation into its effectiveness. Dr. E. M. Moore of Rochester was president of the State Society in 1874 and he said then that a committee of three had been appointed in 1844 by the Monroe County Society to study the question of State regulation. The members of the committee were Dr. Reid, "who firmly attached his name to the method of reducing dislocation of the hip by manipulation," Dr. Backus, "then a member of the State Senate and who became prime mover in the establishment of the school for idiot children at Syracuse," and Dr. Moore who said

In this country, there happened to be a pestilence of Thompsonianism of marked virulence and Dr. Backus produced the passage of the act now in force. This form of quackery, under the name of Electricity, has still a feeble hold on the community but I strongly suspect that legislation does little or nothing to prevent or sustain any form of practice and the law as it now stands, in this particular, is nearly as it should be.

This committee appointed by the Monroe County Medical Society wrote to all the State Societies asking if those states had laws regulating the practice of medicine and

surgery and if so, what they were. Thirty-two states replied. Never having such a law were eight states—New Hampshire, Rhode Island, Pennsylvania, Virginia, North Carolina, Kentucky, Tennessee, and Missouri. Ten states formerly had laws but repealed them—Maine, Vermont, Massachusetts, Connecticut, Maryland, South Carolina, Alabama, Mississippi, Indiana, and Ohio. Four, including New York, still had laws—New Jersey, Georgia, and Louisiana. A number of these State Societies spoke feelingly of the flourishing of quacks and patent medicines.

The Commission appointed by the State Society reported that quackery and patent medicines abounded everywhere despite law and penalties and that public opinion was not tolerant of laws regulating medical practice. They recommended (1) that in the present state of the public mind, all penal and prohibitory enactments are inexpedient, (2) that it is conformable to the spirit of our public institutions to leave perfect liberty to all to practice medicine, being amendable only for injury done, (3) that all legislation relative to the practice of medicine and surgery, as in all other arts and sciences, should aim to encourage, by affording such privileges as may be necessary to its highest prosecution, (4) that the important, if not the only remedy against quackery, is medical reform, by which a higher standard of medical education shall be secured.

Dr. Green, president of the Herkimer County Society, said in 1845¹

In order to render the profession more respectable and more worthy of the confidence of the public and at the same time to take measure

* Continued from our November 1 issue.

DISTRICT BRANCHES

Second District Branch

The thirtieth annual meeting of the Second District Branch of the Medical Society of the State of New York will be held at Garden City in the Garden City Hotel, November 19

The program begins at 10 A M and continues until 5 P M, with intermission for lunch (12 to 1)

Six comprehensive exhibits on the subjects listed below will be shown. All phases of the subjects will be illustrated, and every possible graphic method utilized—charts, models, photographs, x-ray films, gross and microscopic pathological material, and actual apparatus used in diagnosis and treatment.

1 The modern concept of tuberculosis and how it should be treated

2. Diabetes—its routine treatment How to

prevent emergencies which occur in diabetes and how to treat them if they occur

3 What every practitioner should know about the diagnosis and treatment of fractures

4 How can we find cancer early, and what can be done when it is found?

5 Newer knowledge concerning lead poisoning

6 Recent advances in our knowledge of the phylogeny, anatomy, and physiology of the blood forming tissue. How this knowledge has effected our treatment of blood diseases

During the afternoon there will be a meeting of the Woman's Auxiliary with program and entertainment for the ladies

At 7 P M the annual dinner is scheduled to be followed by dancing. A short business session will be held immediately after the dinner for the election of officers

THE LEGAL MUDDLE OVER INSANITY

Insanity, which is quite apart from mental disease, is a monstrous creation of lawyers causing many evils. This was declared dramatically by Dr Smith Ely Jelliffe, at the New York Academy of Medicine on Oct. 8

In his address for the laity, about "The Historical Background of Psychiatry," Dr Jelliffe, editor of the *Journal of Nervous and Mental Diseases* and veteran alienist of countless legal battles, traced the concept of "insanity" to ancient Roman lawyers

Thick-headed, aggressive, possessive minded, impatient of Greek scientists, these Romans created the muddled thing called "insanity," he asserted.

Said Dr Jelliffe of American lawyers and courts today

Side by side with the concept of mental disease there has run this legal monstrosity, insanity. Few there are who can separate the concepts. Thus we hear the asinine statement, "So-and-so is medically insane, but legally sane."

Insanity is not a medical concept. It has no place in psychiatry, the science of mental diseases

Only courts of law can make insanity. Definitions of insanity vary more or less in the 48 States of the Union, although they all follow a uniform pattern. If a person has mental disorder or defect of a degree sufficiently

variant from the average judgment of his fellows, he shall be judged incompetent, irresponsible, insane. He shall become a ward of the State, with respect to his liberty and his property

How the different legal definitions confuse us was shown by examples. New York law sends a killer to the electric chair, holding him sane, if he knew the nature and quality of his act and its wrongness. But New Jersey law will judge him insane even if he knew what he was doing and that it was wrong, provided he was unable to resist an impulse to kill

The absurdity of the whole procedure from a scientific viewpoint was described as more poignantly patent considering certain chemical effects on the mind. Dr Jelliffe stated that

In alcoholic intoxication, delirium of fever, ingestion of thyroid substance or too much insulin, causing hypoglycemia, a man does not know the nature and quality of his act, or that it was wrong. Even the alcoholic phase might be a symptom of epilepsy, many drinking sprees are. Then where are we?

The law in relation to matters of psychiatry is full of such dumb cluck tricks. To pull their own chestnuts out of fire, lawyers roar about the venal alienists. The public doesn't know the legal tricks and are always hoodwinked. The procedure usually is a farce from beginning to end

also many had obtained the medical degree easily and carelessly from some of the medical schools. We read that same charge in 1825 by Dr Manley in his annual address. He explained that the medical societies erred because of the latitude of construction given the provisions of the law. He charged the medical schools with giving too limited courses and accepting students unprepared by education to take up medical studies. He deplored the wholesale manufacturing of physicians.

The Monroe County Society passed resolutions which are recorded in the State transactions concurring in the wisdom of the revision of the law but recommended that all physicians continue to support County and State societies. The law, as most of the practitioners interpreted it, no longer required that all practicing physicians be members of the County Society, although many of the County Societies argued that no such change had been made by the new regulation. One benefit was claimed by members of some of the County Societies, who said they were no longer compelled to accept any licensed physician as a member but were free to elect whom they chose, making membership a privilege rather than a right and also giving them the power to disapprove an individual by refusing him membership. Further changes wrought by the new law were that there was no penalty for practicing medicine without a license. Both medical men and quacks considered this a recognition of quacks as medical men, to the delight of the quacks. These quacks of whatever persuasion or claims now practiced openly and charged fees for their doubtful services. The public which had so earnestly desired freedom of choice, could now knowingly or ignorantly choose anyone to treat the sick. Many were unable to distinguish between pretender and physician. Often they did not know whether Dr Blank had an M. D. after his name, or, if he had, what it indicated. We notice that in the early Rochester directories that some who had been listed as "Botanick Doctors," after this time were listed as simply Dr Blank, without any explanation regarding the omission.

The medical profession was much to optimistic in thinking that the public would distinguish between physicians and quacks. Dr Brismade said at the State meeting in 1858

I believe there is not a town or city in this State, in which there is not more money paid to irregular practitioners of various names and for nostrums and patent medicines, than is received by regularly educated physicians of those towns and cities and I am inclined to think the number of diseases partially treated and maltreated in this random way is fully as great as those submitted to more rational treatment.

We may understand the gullibility of the public in believing the claims of these false practitioners when we remember the high ethical standards of the true medical men which forbade advertisement of any kind and observe the self laudation of the pseudo-physician. We appreciate their pseudonym, "quack."

Stephen Rogers, M. D., President of the New York Medicolegal Society in 1872 said

During the last fifty years, the idea has been very prevalent and has been vehemently advocated by some of the most prominent men of this State, that improved education of the people would correct the liability to imposition by medical imposters. But it must have become apparent to every observing physician that this is a purely utopian idea. The people of our day have a right to the assurance that those who offer to serve them as physicians are intelligent in the subject and it is the plain business of the profession to do all possible to provide that certainty. In the opinion of this author, public confidence was destroyed and legislative control of the practice of medicine discontinued, on account of professional avarice and corruption in connection with medical colleges.

In that same year, Dr Rogers remarked to the New York State Medical Society

The accumulated evidence goes to convince us that neither the acts nor resolutions of medical societies nor of medical colleges nor even their united action, unaided by the strong arm of the law, will ever assure the people that the sign "Doctor" on a door or on a circular or on a card is a guarantee that his knowledge of medicine justly entitles him to claim public confidence.

While medical societies may guard themselves from evil and criminal association, they have, at present, no power by which they can protect the people from this danger and contamination. If there be no sectarian discussions, no further wrangling over therapeutic doctrines, which the public will never appreciate, but a united effort upon this grand requisition of education, the public will support it.

There seemed to be little bitterness in the medical societies because of the repeal. They

for its improvement, I would urge that the time of study be extended and the requirements as to qualifications for entering the profession be more exacting so that a sufficient time be required in preparation of the study. In this way will it be raised so far above quackery that the public will easily discern between their respective claims to patronage and respect which is due it.

The Select Committee on Petitions, praying for repeal of laws restricting medical practice, said in the conclusion of its report, "A people accustomed to govern themselves and boasting of their intelligence are impatient of restraint, they want no protection but freedom of inquiry and freedom of action." The State Society remonstrated against repeal of all law regarding medical practice and humbly asked for modification, requiring only (1) that the candidate asking to be examined for license, prove that he studied with an authorized practitioner, that he was twenty-one years old, of good moral character, had competent knowledge of the English language by submitting an essay on a medical subject, (2) that he had attended one full course of lectures at an incorporated medical college, (3) that he pass an examination before the Censors of the State or County Society and receive a license to practice, (4) having satisfied these requirements, the president to give a certificate which should be filed with the county clerk. The *Albany Evening Atlas* reported² a Mr. Scott's impassioned address before the Senate that year wherein he charged the medical men of the state of many things, including intolerance and want of knowledge and progress in their profession. He concluded, "The people of this State have been bled long enough in their bodies and pockets and it is time they should do as the men of the Revolution did resolve to sit down and enjoy the freedom for which they bled."

Mr. Carpenter, of the Select Committee, seemed to have even less appreciation of the medical profession for he said³

There are many who believe that the study of the healing art may be pursued to as great advantage by the inquiring and enlightened mind by reading the great book of Nature, which a wise and bountiful Providence has spread before him and obtain from it as great a knowledge of the healing qualities of roots and plants, flowers and leaves, as can be obtained from the study of musty books in the halls of the institutions of *materia medica*, and having acquired this knowledge and proved

the efficiency of his botanical preparations, he is as much entitled to the confidence of the public and should be allowed the same privilege to receive compensation for his services as is granted to the licensed practitioner.

In this day of restricted medical practice, with high educational requirements, required licensing, and with heavy penalties inflicted upon the unlicensed practitioner, the ignorance of that time and the lack of appreciation of the profession upon the part of the law-makers and of the public, is almost incredible. That the protection which the law had been giving the public against quackery should be regarded as a restriction of the freedom of the people now seems ridiculous.

So it came about that after eighty-four years of legislative regulation of the practice of medicine, the laws were repealed in 1844 and the door flung open to any who cared to enter.⁴

Consequently the learned and the ignorant, the physician and the empiric, enter the arena even-handed to compete for public favor. The laws of 1844 repealed nothing and exacted nothing which impaired the requirements of the previous statutes in regard to the study of medicine, the qualifications of physicians or the powers, functions and duties of medical societies. The scope and intention of the whole act is to open the practice to all who choose to avail themselves of the permission and to submit to the penalties which, in certain cases are therein provided and not to interfere with medical men, medical societies or medical colleges or universities.

The medical profession had felt since the organization of medical societies, that the association of physicians and surgeons was to their mutual benefit in the exchange of ideas and experiences and in the excitement to emulate or excel. They felt that the examination of students not only aroused the ambition of the student and improved the quality of new practitioners but also excited the pride of the censors themselves and a desire in them for an improvement in medical practice. The public did not recognize that the former laws were for its protection but rather considered them a grant to monopoly for the physician's benefit alone. Dr. S. A. Cook, in addressing the Rensselaer County Medical Society, said that the profession itself was partly to blame for this misunderstanding, for many had been admitted to practice without proper qualifications by careless County authorities and

never quite a hundred. The average attendance at the annual session of this Society for the first decade was sixteen, for the second decade twenty-three, the third, thirty-six, the fourth, forty-six, the fifth, sixty-four, the sixth, one hundred forty, while for the past eight years the attendance has averaged one hundred fourteen.

Nearly one-half of the presidents and one-fourth of the vice-presidents have been professors in medical colleges. Two-thirds of the presidents and nearly one-half of the vice presidents were dwellers in populous cities. Eighteen counties have furnished all of the presidents for sixty-two years, two counties have filled three-fourths of the terms, twenty-four counties have furnished vice-presidents, four counties have filled this chair twenty-five terms and the presidential chair forty-seven terms—in all a little over one-half of the time.

Albany has had ten presidents, who have served nineteen years and five vice-presidents who served eleven years. New York (City) has also had ten presidents, covering sixteen years and three vice-presidents. Next in order comes Oneida, which has filled the chairs eight years with presidents and three vice-presidents, Otsego, four and eight, Monroe, three and none, Onondaga, two and four, Columbia, two and three, Madison and Erie, each two and one; Chenango, one and four, Cayuga, one and three, Kings, one and two, Cortland, Dutchess, and Westchester, each one and one, Chemung, one and none, Herkimer and Montgomery, each five vice-presidents, Oswego, two, Broome, Chautauqua, Fulton, Greene, Ontario and St. Lawrence, each one vice-president for single terms.

We are indebted to this president for giving us this data regarding the workings of the State Society. Other statistics were needed and had been asked for by the State Society for some years—the vital statistics of the State. In 1858 the vice-president of the State Society remarked that according to the census of 1855, there were more than 6,000 physicians in the State and that if one in six of them reported four cases much would be contributed to the general knowledge concerning diseases in the State. In 1857 the State Society asked the County societies to pass resolutions to secure a uniform and permanent registration of births, marriages, and deaths. Here again, was found the need for cooperative effort between the County Societies.

Another outstanding feature of the period was the development of independent County and State Societies. The New York Pathological Society met twice a

month, the New York Society of Statistical Medicine met monthly, the New York Academy of Medicine, the Medical Association of Southern Central New York, and the Buffalo Medical Association held regular meetings. From these societies came annually 4,500 pages of medical material, of which about 3,500 pages were entirely original.

Frequently state presidents in their annual messages told of changes in the practice of medicine. President Alden March in his semi-centennial address in 1857 said that twenty years earlier club-feet and crooked eyes were seen frequently on the streets but had become scarce since the introduction of tenotomy. Less than fifty years before, compound dislocation of large joints demanded amputation, now decayed bone was being removed, joints excised, and limbs saved. Knowledge of *materia medica* had greatly increased and a nearer correct view of prophylactic and hygiene measures entertained. "In the first sixty years of the eighteenth century, one-half of the population lived over twenty-seven years. In the latter forty-years, one-half exceeded thirty-four years of age. At the beginning of the present (19th) century, one-half exceeded forty years, and from 1838 to 1845 one-half exceeded forty-three years. The average longevity at these successive periods has been increased from eighteen years in the 16th century to 43.7 by the last reports." Contrasted with the less than one-half dozen medical schools in the United States in 1807 and about the same number of hospitals, there existed in 1857 forty medical colleges or associations where medicine and surgery were taught and about twice that number of hospitals were scattered about the United States. Speaking of advances made in related sciences, Dr. March said that, "half a century ago organic chemistry was not known as a branch of chemical science. Within the last few years organic chemistry has made enormous steps but they still too evidently are the unsteady tottering steps of a young giant."

We have spoken of the high ethical code adopted by the medical profession in this state and how it was maintained and enforced through the years. It fashioned a pattern of behavior for a physician and a gentleman. Admiring the profession for

still continued to examine medical students and to issue licenses. It was the general opinion among them that the only legislation needed was to "provide a body of competent physicians and to give the public the means of recognizing them, leaving to the prudence of individuals to choose discreetly, and that all attempt to coerce people to discretion was wrong in principle and unsuccessful in practice." This was not the first time that the medical profession had this erroneous opinion. At the time of the passing of the law of 1844, a committee of the State Society in making a report regarding its repeal which had been suggested, said

We have laws enough and good laws. Quackery must be suppressed, not by legislation but by enlightening public opinion as to its dangers. The dignity and respectability of our profession is to be promoted not by asking for legal privileges but by an increase of individual zeal and a more cordial cooperation. It is a great error to suppose that a repeal of the restrictive laws put the physician on a level with the quack and takes away the barrier which separates them. The barrier which separates the two classes is formed by the higher attainments and honorable deportment of the members of the latter, and this is a barrier which depends on us to make higher and higher. It is the one which quackery will not surmount and which no legislative enactments can break down.⁵

Perhaps we can speak of the period we have just been describing as beginning the second era in the history of organized medicine in New York State. The first began properly in 1806 with enactment of the law to establish State and County Societies and ended in 1844 with the repeal of legislative regulation of the practice of medicine.

County organizations now began to decline, and in some of them the regular meetings were discontinued. Physicians stated that they were too busy, that it was difficult to leave patients to attend meetings, that the expense and loss of time was too great and also that the proceedings were neither interesting nor profitable. We must remember that transportation was then difficult and expensive as well as time consuming. The State Society tried to make the practitioners see that the law requiring all physicians to join a County Society had not been changed. That part of the law had not been repealed, it is true, but neither was there provision made for

enforcing it. The Transactions of 1858 state that the licensing power granted by statute, to the State and County Societies had become a dead letter as the college diploma almost covered the ground. That year no licenses had been issued by the State Society. Another reason for sustaining County Societies was the needed support of the State Society and of the American Medical Association. Each County Society was entitled to as many delegates to the State Society as that county had representatives in the State Legislature and the State Society in turn sent delegates to the National convention.

Pleading for stronger County Societies, President Weym said at the State meeting in 1872

An element like a medical organization, regularly and earnestly sustained, has so often proved the means of resisting error among the people, of inducing obedience to the standard of ethics and of individual profit and advantage to its members, that its value cannot be adequately estimated. No one who has observed the evidence of medical growth and strength will question that incalculable good develops out of professional intercourse that has passed beyond the technicalities of constitutional amendments and the alteration of by-laws and attained a condition that savors of legitimate scientific improvement.

One more presidential address may be quoted in part because of its historical and statistical information. It is that of Dr. George Jackson Fisher, president of the State Society in 1875. He said

In 1806 when the law to incorporate medical societies was enacted, the State of New York was divided into thirty-five counties and now into sixty. The entire population was then 700,000 and now 4,000,000. Then about 800 doctors, such as they were, practiced medicine without ethics or organization or legal restraint and now 6,000 physicians, such as they are, make up the ranks of our State medical army—not a few of these still sadly in need of regulating. Albany then had 1,000 houses and 7,000 inhabitants, now 80,000 people. Buffalo then had 1,508 inhabitants and now is eleventh in the United States with 120,000 inhabitants. Where were Troy, Utica, Syracuse, and Rochester? They had no existence [1806].

The attendance at the first meeting (of the State Society) was twelve, at the last, two hundred fifty-five. It did not reach twenty-five until the fourteenth annual session. Forty-two years passed before the attendance reached fifty and during the first half century it was

ence upon organized medicine. Dr Hans B Gram, the first homeopathic doctor to come to this country, arrived in New York City in 1825 and was the sole practitioner of that school for two years but within ten years a New York Homeopathic Society had been formed with nine members and in 1841 a new organization, the New York Homeopathic Physicians Society was founded. The State Homeopathic Society was organized a little later King gives the following numbers of early homeopathic practitioners

1852-	301	1880—	968
1857~	433	1899—	1203
1870-	727	1904—	1206

That the homeopathic practitioners were regarded as quacks for many years is evidenced by the many disparaging remarks made in the annual presidential addresses of the State Medical Society. As we study the State medical annals we are persuaded that some of the so-called homeopathic quacks were without doubt, truly quacks hiding behind the standard of homeopathy and committing misdeeds in its name.

The Transactions of the New York State Medical Society contain an address by Dr Thomas Blatchford, president of the Rensselaer County Medical Society in 1842, fifty-five pages long, on the subject of homeopathy. In defining homeopathy he compares it to a "footless stocking without a leg." In scathing language he condemns the claims of homeopathy and its pharmacopeia. He quotes from two letters from past presidents of the State Society, one from Dr John B Beck of New York who says he knows of nothing more absurd than homeopathy and one by Dr John Stearns of the same city, who calls homeopathy the most sublimated imposture ever registered in the annals of medicine.

Again, in 1845 the Transactions record an address given before the Herkimer County Society by its president, Dr L Green. He said

While we can not but lament the vices and folly of human nature, if we examine closely we shall find that wherever ignorance bears sway there quackery flourishes most and that this is the soil in which it is fostered and nourished and in which it grows most rapidly and luxuriantly all grades from her who scrupulously adheres to "yarb and root" teas, and him who deals in vapor baths, lobelia and cayenne pepper glysters and who most religiously eschews the use of all minerals what-

ever, through the long list of cancer doctors, Indian doctors, German doctors, Hydropathists, to him who practices after the algebraic principle, that two negatives make an affirmative, who prescribes one evil to cure another of like magnitude, or in other words, would add fuel to *put out* the fire, who will undertake to cure a most inveterate case of fever and ague with an infinitesimal portion of medicine in a specified time—we will find that each separate system owes its origin and continuance and existence to either ignorance and credulity, avarice and ambition, superstition or all combined. All these systems, like their predecessors, must and will have their day as long as the causes above cited exist, but it is a fact by no means encouraging, that while each system in its turn explodes or dies a natural death, numerous others rise up "Hydra" like to occupy its place, while the true science of medicine has continued steadily to advance, unshaken by false and absurd theories—but gradually, progressing and improving, has at last attained a stand among the professions second to none.

In the same volume, Rensselaer County again casts its disapproval upon the new treatment in an address on the progress of medical science by Dr Simon A. Cook. Speaking of impostures, he stated, "True, the influence of amulets and charms and incantations has passed away but we have in their places the mumeries of magnetism, the ravings of Thompsonianism and the infinite follies of Hahnemannism." At the annual meeting of the Monroe County Society in 1845, its president, Dr E. W. Armstrong said, "The absurdities of homeopathy have already been sufficiently exposed, to convince those who will take the trouble to examine and reflect, of its utter worthlessness and that as a system, if system it may be called, it has no foundation but the vagaries of a disordered mind or the deliberate but ignoble design of immortalizing the name of its author, at the expense of common sense, truth, and decency." Dr Armstrong, like many others of his time, predicted an early ending of the practice of homeopathy.

In 1847 the Transactions give an address by Dr Joseph Bates who spoke at the annual meeting of the Columbia County Medical Society. He spoke of quackery in its various forms and in condemning those who were advocating the "electric theory" said, "I should suggest a heated oven at the temperature of 500 degrees Fahrenheit to cure every man or woman, practicing Mesmerism, Homeopathy, Hydropathy,

its high standards which it struggled to maintain, it comes as a surprise and shock to learn, while reading through the old Transactions, that this same fine old code became a stumbling block and finally created a rift within the rank of the State Society, a break that caused a twenty year separation of old professional brothers, separated from each other in two State Societies and at the same time, causing them to be cast from the fold of the American Medical Association. The same great organization, the American Medical Association had been formed through the efforts of the members of the New York State Society and it was with grief that the New York men received the ultimatum that the doors of that body were absolutely closed to them.

That we may better understand how this break came about, it will be necessary for us to retrace our steps and consider briefly the rise of homeopathy in the State of New York, for it was disagreement regarding the recognition of homeopathic practitioners which caused a change in the code of ethics and at the same time the rift in the State Society.

Chapter IV

The Two State Societies and Their Union

Formation of the A.M.A., Rise of Homeopathy Feeling against Homeopathy, Legalizing of Homeopathic practice, the New Code, Split in State Society and formation of another State Society the two Societies united in 1906

To New York State has been given the credit of founding the American Medical Association. The first attempt to form this society came in 1839 and the second in 1844 but it was two years later that success finally came. The object in organizing the American Medical Association was to raise the standard of the profession by closer supervision of medical schools. Many schools had opened and competition was great among them and in order to attract students, terms of study were shortened requirements for entrance were lessened, and examinations for graduation simplified. It was impossible for any one state or a small group of states to remedy this condition. It could be done only through the concerted efforts of all the state societies, acting together in a national organization.

By invitation from the New York State Society, delegates from many medical institutions and societies assembled in New York City in May 1846 and appointed committees to prepare plans for a national society. This new society was to consider standards of medical education and also to prepare a code of ethics and a nomenclature of diseases. It was to be an organization in which members "shall collectively represent and have cognizance of the com-

mon interests of the medical profession in every part of the United States." In May of the following year the American Medical Association was formally organized in the city of Philadelphia.

In this manner the largest and no doubt greatest medical organization in the world was created and New York State is recognized as its founder. The ethical code of the New York State Society had been in existence for many years and the new code of the American Medical Association was not greatly different. Proud of their code and of their part in forming the National body, the members of the New York State Society sat in bitter grief when this same code was made the cause of a break in the State Society and its expulsion from membership in the American Medical Association. In order that we may understand the entire cause of this separation, we must consider briefly the rise of the practice of homeopathy in this state and discover why the gradual recognition of the homeopathic practitioners led to the quarrel in the State Society.

The early history of Homeopathy is interesting and is discussed at length in the four volumes by King¹. We can only mention its rise in this state and its influ-

Transactions of 1862 include resolutions from the New York Academy of Medicine protesting against the employment of any homeopathic physicians in the army, their methods being closely allied to quackery and such appointment would dissatisfy and dishearten the medical staff of the army, "who understand the true character of homeopathy and who have entered the service of their country with confidence that the government would strive to elevate the standard and promise the efficiency of the medical staff" The State Society approved the resolution.

About that time, the County Homeopathic Societies began to organize, beginning with that of Albany County in 1860. By 1865, most of the counties had been organized and their societies met regularly. Homeopathic hospitals were erected in various parts of the State, the one in Brooklyn growing out of the old Brooklyn Homeopathic Dispensary which opened in 1852. Children's hospitals, hospitals for women, and maternity hospitals were erected by the homeopathic men who had been refused admittance into the "regular" institutions.

Another class of medical practitioners, the Eclectics, sought recognition by the Legislature. We learn little of the Eclectics from the transactions of the State Society, the name being mentioned but seldom and then, merely as one in a list of so-called quacks. In 1865 this medical society was also recognized by law and an unusual situation now arose. Dr Henry R. Hopkins in his inaugural address in 1903, said

In 1857 the unity of the medical organization of the State of New York was broken by the creation of a second system of societies, State and Counties, having the same general and local powers and privileges as those authorized in 1806 and in 1865 was still further interrupted by the authorization of a third system of medical societies, State and local, and since that date there has existed in our State the monstrous anomaly of three distinct classes of physicians having equal authority to practice medicine and equal privilege to enjoy the honors and emoluments of that practice, that this unfortunate condition of medical malorganization was inimical to the best interests of our profession, history will abundantly attest.

In 1867, two years after the Eclectics were legally recognized, Dr Joseph C Hutchison stated in his presidential address to the State Society, in commenting upon this triple system of medical practice,

"Today the enlightened and skillful votary of legitimate medicine occupies in our State the same legal standing as he who sacrifices his common sense and his conscience in the fraudulent practices of the most odious quackery." So for many years the State of New York had three Medical Examining Boards, with greatly varying examinations and requirements.

Dr Hutchison also told of the struggle with the homeopaths during the summer which had just passed, while the cholera epidemic endured in New York City. The Sanitary Committee of the Board of Health had recommended that permission be granted to homeopathic physicians by the city to assist in a given proportion of the hospitals but the Board of Health ignored the recommendation. Dr Hutchison in strong terms criticized the Committee for thus exposing the patients to inefficient care and also charged the members with a violation of the ethical code in countenancing quackery.

Rebuffed at every hand but heroically carrying on, we find the Homeopathic practitioner finally coming into his own. How that came about is another dramatic chapter in the unusual history of the New York State Society.

We may say that the first act of the new drama opened on February 7, 1882 when Dr Abraham Jacobi, president of the State Society, on the first day of the annual meeting called upon the Committee on the Code of Ethics to report on proposed amendment of the code and it was voted to devote the entire evening to consideration of the report. The report was read, discussion was opened and Dr D B St. John Roosa of New York spoke at length against acceptance. He objected that many of the out-worn and controversial parts of the code had been retained but the rules governing consultation had been so worded that a practitioner could call into consultation any one whom he chose, "be he homeopath, eclectic or the seventh son of the seventh son, an Indian doctor or whatsoever he be." Dr Roosa offered instead of the proposed code, this simple one.

With no idea of lowering in any manner the standard of right and honor in the relations of physician to the public and to each other, but on the contrary, in the belief that a larger amount of discretion and liberty in individual action and the abolition of detailed and specific rules, will elevate the ethics of the profession,

Thompsonianism or any other form of quackery, or for making and vending any kind of nostrum" In no less bitterness are the homeopathic practitioners condemned by Dr W Hooker reporting for the Committee on Medical Education to the American Medical Association, which report is republished in the New York State Transactions of 1852 He stated that only character and education should admit anyone to practice medicine and that the great majority of homeopaths were uneducated men or superficially educated He asserted that physicians who had become converted to homeopathy and therefore expelled from the medical societies had been expelled for the wrong reason They should have been excluded not for their opinions but for misdemeanors, "any act by which they associate with the common herd of homeopathic practitioners is a misdemeanor, which is a proper ground of expulsion"

May we pause here to state, that in citing these opinions of leading men in the medical profession, we criticize neither those condemning nor those condemned Unless we can show the animosity and bitterness which existed between the so-called "regulars" or "allopaths," and the homeopaths and demonstrate how homeopathy through great trials, came to a position of importance and strength, we shall be unable to give a clear picture of the circumstances leading up to the split in the State Society We are trying to portray how year after year, the feeling against homeopathy grew and was publically expressed until the great change came, when this unanimous disapproval in the State Society ceased and dissension came into the ranks of the State and County Societies

To cite a few more examples of the expressions of hatred for homeopathy, in the 1853 records, Dr Jonathan Kneeland, president of Onondaga County Society at the annual meeting classed "as heretical practices, homeopathy, hydropathy, physopathy, kinesopathy and their kindred fallacies, crono-thermalism, mesmerism, animal magnetism, eclectism, etc." Dr Edward H Parker, president of the State Society, addressed that honored body at its annual meeting in 1862 and, in speaking of the credulity of man, gave examples of man's simple belief and added, "I draw my illustrations from the homeopaths only because they happen to be just now the most

fashionable of quacks" Again, it was the president of the State Society, Dr Daniel P Bissell in 1864, speaking on medical progress, who said that instead of looking upon homeopathy as a harmless folly or a useful satire on medicine, the public should be awakened to a sense of its debasing and destructive effects "Duty demands," he said, "that we should consider and expose these changing errors and impostures as they arise and take care meanwhile that they find no shelter or protection under the garments of truth and medical science."

In his anniversary address in 1875, the president, Dr George Jackson Fisher, calls homeopathy "the most stupendous fraud of the present age, the greatest delusion and the most subtle snare with its system of specifics and potencies, its infinitesimal pharmacy and therapeutical juggery"

But what were the practitioners of homeopathy doing during this time of condemnation from the members of the State Medical Society; were they sitting in quiet hope that the storm would pass or were they striving for a place in the sun? They were not sitting still Refused admission into the State and County Societies, they organized their own societies They built their own hospitals and medical schools and published their own books and periodicals, but only after long years of struggle, during which time their membership grew in numbers and strength

A homeopathic medical school was founded in Philadelphia as early as 1848 but the Legislature at Albany refused to charter such a school in New York State in 1846 and again in 1853 In 1880, however, a charter was granted to incorporate the Homeopathic College of the State of New York in New York City Nine years later its name was changed to the New York Homeopathic Medical College. The law of 1844 required the licensing of all physicians and the medical societies refusing admittance to practice any that were homeopaths, these men were subject to the law for practicing without a license until, in 1857, the Legislature of the State allowed the homeopathic societies to incorporate. This act is spoken of as the legalizing of homeopathy

During the Civil War homeopathic physicians, claiming that many of the soldiers preferred homeopathic treatment, offered their services but were refused. The State

State Medical Association, the new and second State Society. This volume records a meeting held on February 4 and 6 of that year, the day before and the day after the memorable meeting of the New York State Medical Society, when the new code was upheld. Seventy-six attended the meeting on the fourth. Dr Austin Flint of New York County offered a resolution that a new organization to be known as the New York State Medical Association be formed. Its immediate object should be to support the old code and be a part of the American Medical Association. Dr E. M. Moore stood alone among the speakers, asking that the resolution be laid on the table for one day until the New York State Medical Society had met and a vote taken on the new code, that vote then being in order. Dr Moore further suggested waiting for another year or even five years if necessary, until there was a change of heart in the old organization. However, a vote was finally taken upon Dr Flint's resolution and carried unanimously, it being understood, apparently, that if the vote in the old State Society should unexpectedly repeal the new code, then the new organization would be unnecessary.

The new code was ratified in the old State body the next day. The new organization met a day later, elected its officers, appointed committees, divided the state into districts, and prepared for incorporation. Dr H. D. Didama was chosen president. The first annual meeting was held the following November in New York City. From that time on, until 1906, for twenty-two years, there existed two medical societies of the State of New York, unhappy years for both organizations. Because we must bring this record to a close, we must omit the transactions of the two societies during those years of alienation, years during which little was accomplished for medicine through legislation, and relate how they gladly amalgamated once more. Members of the old State Society who had met as brothers year after year, now met in hostile camps, thinking of each other only with bitterness. They differed upon a matter of principle and each thought himself right. But rancor and bitterness lessened as the years passed. Younger men entered the group, understanding little of the old struggle and caring less. They saw only the futility of the two societies and the older men forgot

their bitterness and longed for the association of the old friends still living. Their grief at separation had outlasted their anger at its cause and they yearned for reconciliation. Many of the men, old and young, had joined both societies and more and more the two organizations grew alike.

Again we turn to the presidential addresses to witness this change of sentiment. Dr Henry L. Elsner, president in 1902, asked for greater liberality in the admission of members into the State Society. He said that the State Legislature did not discriminate in its treatment of any school. "We know no pathy, dogmas have long since faded from our memories. Let us continue to exert our influence in favor of unification of the profession, our doors are open to all who practice rational and practical medicine, to all who are willing to discard dogma and who have given the State proof of proficiency and are of good moral character." He stated further, that the time had come for a final effort having for its object, the gathering of the profession of this State under a single banner upon a liberal platform and with representation in the American Medical Association. He recommended that the Medical Society of the State of New York appoint a committee of five to confer with an equal number representing the New York State Medical Association for the purpose of formulating a plan which should have for its object the reorganization of the regular profession of the State, this body to be in affiliation with the American Medical Association, this committee to report at the next meeting. The president's recommendation was adopted.

While the New York State Society delegates were excluded from the American Medical Association, the members of the State Association were received by that body. Dr John A. Wyeth, president of the New York Medical Association in 1901 was president of the American Medical Association the following year, when the National organization met at Saratoga Springs. When the State Association "extended the olive branch" to the older State Society, as Dr Alvin A. Hubbell, president of the State Association in 1902, said in his annual address, one of the inducements offered, was membership in the American Medical Association. He said that no progressive physician could afford not to

the medical profession of the State of New York, as here represented, hereby resolve and declare, that the only ethical offenses for which they claim and promise to exercise the right of discipline, are those comprehended under the commission of acts unworthy a physician and a gentleman.

Many delegates arose, some to agree with Dr Roosa that the code should be discarded entirely, others to state that a code was definitely needed. Dr E M Moore of Rochester moved an amendment to Dr Roosa's substitute, proposing that the subject be brought before the American Medical Association for consideration first. Dr Moore agreed with earlier speakers that the A.M.A. code was unusual and said he had investigated its source and found it had been copied almost verbatim from "a treatise written by Dr Samuel Percival in 1760, in accordance with the condition of society presented in England at that time, which was entirely aristocratic, governed by the law which regulates the relations between patron and client." Dr Moore's motion was lost.

Most of the discussion on the proposed new code was upon the question whether homeopaths might be called in consultation in cases. That morning, the president, Dr Jacobi, had remarked in his opening address that a change had come in the situation in the State. He said the homeopaths had made overtures to the profession, claiming that they no longer differed in practice and Dr Jacobi recommended that therefore the old boundaries should be abolished. After much discussion a vote was taken and the report of the Committee on the Code was adopted, 52 voting for and 18 against.

The next year, 1883, the president, Dr Harvey Jewett in his opening address stated that news of the adoption of the new code had not been well-received, that county societies expressed dissatisfaction with the code as unbecoming to the dignity of the profession and revolutionary in its nature and disorganizing in its tendency. He also stated that the American Medical Association had refused admission to the delegates from New York because the new code was too progressive and too liberal in spirit in reference to established rational medicine existing at the time. The objectionable clause was the one permitting consultation with any legally recognized practitioner of medi-

cine. He asked that the Society consider the code again whether to confirm, modify or abolish it.

After letters from numerous county societies were read, objecting to the new code, a motion was carried to repeal the new code, permitting the old code to stand and a new Committee to suggest changes at the 1884 meeting. In 1884 the code again came up for consideration. It was claimed by many that at the time of its adoption, there were too few delegates (70) present and that the membership at large, while knowing that a change in by-laws was to be suggested, did not know that so radical a change was contemplated, nor if they had known, would have approved. The membership of the County Societies resented the fact that the National Association had closed its doors to the New York State delegates.

Dr H D Didama spoke of the meetings of the State Society which before 1882 had been joyful occasions, scientific matters being discussed without acrimony and delegates parting reluctantly as brothers. Since 1882, he said, angry discussion had taken the place of friendly debate and the Society was divided into factions threatening a permanent rupture with old friends turned into lasting enemies. Dr E. Mott Moore read an article from the *Journal of the American Medical Association* of 1884, in which the members of the National organization are reminded of the formation of that body in 1847 in Philadelphia, the delegates having assembled upon the call of the New York State Society members, also that the New York State men assisted in forming the laws and the code and that it was the duty of the New York State Society before changing its code, to bring the matter to consideration before the National organization.

The resolution of Dr Didama of the year before, was then brought to vote. *Resolved*, That all action taken at the annual meeting in 1882, in regard to changing the Code of Ethics, be repealed, leaving the code as it was before such action was taken. There were one hundred five votes cast in favor of the resolution and one hundred twenty-four against. Thereby was the new code established.

For the second scene in this drama, we turn to the transactions of July 1884 of the first regular meeting of the New York

rollment of 10,000 New York State practitioners in the American Medical Association, constituting twelve per cent of the membership of the National body. By 1924, the activities of the State Society had expanded to such an extent, that it was necessary to increase the dues to ten dollars a year. A salary to the Editor of the *STATE JOURNAL* was one of the expenditures now made possible. Another important activity of the Society, the giving of postgraduate lectures before the County Societies, was also begun the following year. The amending of the Medical Practice Act was probably the most important transaction in the years that came after.

With the enumerating of these few activities of the State Society, we conclude this part of the record. Much has been omitted of the great work the organization has done through the years. Walsh in his history has related many of these important transactions. Many more of interest might be told. This limited history of organized

medicine in the State of New York has been written, as was stated in the beginning, that a better understanding might be gained of the Medical Society of the County of Monroe and its transactions and to the story of that Society we will now proceed.

Since the one hundredth meeting of the State Society and its reunion that year, 1906, great good has been accomplished in the State, in matters of medical interest and all this is reflected in the acts of the County Societies. While the story of this later work would lack the dramatic appeal of the earlier history, it is no less wonderful and productive of good to the public and to the medical profession itself. Its telling must be deferred to another record.

We turn now to the story of the Monroe County Society and endeavor to catch the reflection of the great work of the State Society.

MORE ABOUT THE SOVIET MEDICAL PARADISE

Another glimpse of the rather spotty heaven of socialized medicine in Soviet land is given us in an article well subtitled "Paradise Imagined," by William Henry Chamberlin, in *The American Mercury*. He writes

Much is made of the socialized features of the worker's life in the Soviet Union, of the State medical aid, the rest homes, the number of workers at the opera and theater, etc. A good deal of valuable social work has been done in Russia, as in other countries, since the War, but when the benefits of the Russian workers are closely examined a good deal of the glamor tends to disappear. Take, for instance, the quality of socialized medicine. Here we have the interesting recent testimony of Mr. Edmund Wilson, whose writings characterize him as a definitely sympathetic observer of the Soviet Union. During a trip to Russia, Mr. Wilson contracted scarlet fever and spent six weeks in a hospital in Odessa. It is not likely that Mr. Wilson, as a foreign visitor, was assigned to the worst hospital in the city, which is the third largest city in the Ukraine. His report on the sanitary conditions which he witnessed is, to put it mildly, unfavorable.

The bathrooms were garbage piles. The hospital was infested with flies. The wash basin with running water was used for face-washing, dish-washing, gargling, and bedside purposes.

Mr. Wilson's faith, however, was proof against this test. He adopted a method of interpretation which is sufficiently common to call for some analysis. From the deplorable condition of a Soviet hospital in 1935, he deduced how frightful Czarist Russia must have been before 1917. Somehow this suggests the explanation of the patriotic Hungarian hotel-keeper who, in response to a guest's complaint about unpleasant nocturnal insects in 1930, replied, "Well, you know those dirty Roumanians occupied Budapest in 1919."

Several personal experiences have led me to believe, that, whatever may be said for the theory of socialized medicine, its practice in the Soviet Union leaves a good deal to be desired. Once when my wife was in Sochi, a Black Sea resort where malaria is rife, she asked in a drug store for quinine. She was told that the supply was so limited that it could only be sold to persons who already had contracted the disease. The servant of a friend broke her arm. She went to the clinic where she was entitled to free treatment and was sent away by a physician with the assurance that it was nothing serious. Only when her employer engaged a private physician did she receive proper treatment. It is noteworthy that anyone who can afford to patronize the experienced doctors and dentists who still maintain private practice almost invariably prefers to do so, instead of exercising his legal right to free treatment.

be a member of the A M A. and that the only Society in New York State affiliated with it, was the State Association "Then let us," he said, "one and all, seek to impress this fact upon our neighbors and without hostility or controversy, endeavor to enlist them with us and by a process of absorption wipe out the lamentable division of the profession of our State and thus bring it once more into unity."

Two years of active negotiations followed, during which time the committees of the two bodies combined as one with Dr Abraham Jacobi, "the Virchow of American medicine," as chairman. So stated President Algernon T Bristow at the annual meeting in 1904. He said that nearly a quarter of a century ago the State Society had been rent in twain by a dissension which had its origin in a question of principle. Each side had viewed the question from a different viewpoint and the difference seemed irreconcilable. However, "changes in medical education, the establishment of medical examining boards, the elevation of the standard of requirements and the slow progress of advancing years which heals all wounds and finally composes all differences, have made it possible for our brethren, who left us so many years ago, to return to us, who gladly welcome them."

Articles of consolidation were read and adopted. The two societies joined as the Medical Society of the State of New York, with one treasury, with all members of each eligible for membership in the State and County Societies, with the code of the American Medical Association as a suggestive and advisory guide for members in their relation to each other and to the public. Fully expecting that the union would be completed the following year, the members were deeply disappointed to find that a legal technicality stood in the way. It was not until December 9, 1905, that at a special session of the Supreme Court meeting in Rochester, the order was signed consolidating the two medical societies. The first meeting of the united members was held in Albany on January 30, 1906, at which auspicious time, the one hundredth meeting was celebrated.

At this meeting a letter was read from Dr Lewis S McMurty, president of the American Medical Association, inviting the

New York State Society to send its quota of delegates to the next meeting of the National body, to be held in June. The president of the State Society, Dr Joseph D. Bryant, happily announced at this State meeting, that the Medical Society of the State of New York would be fully represented in the House of Delegates of the A M A. The new State Society with over six thousand members now became, as it had not been for many years, a powerful body working for the protection of public health through legislation, raising the standards of medical education and medical practice.

With the close of this interesting drama of misunderstanding, separation, and final joyful reunion in the State organization, we conclude this part of our record. The thirty years which have passed since the reorganization of the State Society, have brought important legislation and changes. The year 1906 was a most successful year after twenty years of divided efforts. The treasury which had shown small yearly balances or sometimes deficits, ended that annual session with a balance of \$3,094 01, with all bills paid. At the time the vote for amalgamation was taken by members of the State Association, 1,517 voted aye, two no, and 295 cast no vote. There were, therefore, over 1,800 members in the Association. Yet when the two memberships were combined, it was found that the old group had gained only 423 members. One cause for the desire to amalgamate had been that so many men had joined both groups and the expense of supporting two State Societies had been excessive.

During the one hundred years of its existence, the Medical Society of the State of New York had been meeting in Albany in January or February. In 1875 a law had been passed in the State Legislature permitting the Society to meet in another city providing a year's notice was given. The law was disregarded and finally forgotten until in 1909, it was revised to permit both a change in meeting place and a change in time. Since that time, meetings have been held in various cities of the State in the month of April or May.

A few other interesting events were the passing of a bill to establish a single, joint Board of Examiners in 1907 and, in 1908, a law requiring registration of physicians by the State. In 1922, there was an en-

that all County cases first be hospitalized in the County Hospital and then, if deemed advisable, they may be transferred to other hospitals" This resolution was carried and the president appointed Doctors Davidson and Brittan

The Economics Committee recommended that the society accept the fee schedule adopted by the Metropolitan area for compensation work and the recommendation was carried.

The guest speakers, Dr Marie P Warner and Dr Benjamin Warner, gave an enlightening discussion on contraception and its technic, illustrated by slides and moving pictures

Dutchess County

ENDORSEMENT of the health institute held Nov 6, when the dissemination of literature on syphilis was discussed, was given by the Dutchess County Medical society at a regular meeting in the Amrita club in Poughkeepsie on Oct. 14 The institute included a meeting in the afternoon at the Vassar Alumnae house and another at night in Poughkeepsie high school

The guest speaker at the medical society meeting was Dr Maximilian A. Ramirez, F.A.C.P., physician at the French and St. Vincent's hospital in New York city His topic was "A Practical Discussion of Allergy"

DR NELSON R. BORST, seventy-nine, oldest practicing physician in Poughkeepsie, has made it known that he plans to retire after forty-six years of active service. He plans to depart in the near future for Florida where he will spend the winter "I'm going to quit. I've been in it long enough," Dr Borst said

The retiring physician was Democratic candidate for mayor in 1915 and served on the Board of Education for eight years and six more on the Board of Health He has been a member of the staff of St. Francis hospital and a member of the courtesy staff of Vassar hospital

Dr Borst intends to continue his pursuit of outdoor sports which includes hunting and fishing in the Adirondacks and golf

Erie County

DR. DAVID LAWRENCE REDMOND, who died in Buffalo on Oct. 13 at the age of seventy-three, had practiced medicine in Buffalo for half a century He received his medical training at the old Niagara Medical University, later merged with the University of Buffalo Medical College.

DR. C. C. KOESTER of Batavia was elected president of the Buffalo Ear, Nose and

Throat Society at the annual meeting in Buffalo He served as vice-president last year The society is composed of specialists in the Buffalo area and holds monthly discussion meetings

Essex County

DR JOHN BREEN of Schroon Lake was elected president of the Essex County Medical society at the annual meeting held at the Elk's restaurant in Ticonderoga. He will take office on January 1 to succeed Dr J. A. Geis of Lake Placid. Dr L. H. Gaus of Ticonderoga continues as secretary

The meeting was attended by 18 members of the county society who received Supervisors Ward, Murdoch, and Carr who discussed medical relief cases Assemblyman Thomas A. Leahy talked on medical legislation

Greene County

A GROUP OF FRIENDS of Dr Horace G. Baldwin, headed by Dr George W. Bassow, presented him with a new, four-door de luxe Buick sedan, recently, says the *Catskill Recorder* The presentation was held at the Baldwin home in Tannersville and showed the high esteem in which Dr Baldwin is held by his many friends and patients in the Summer colonies of Elka Park, Onteora Park, Twilight Park, Platte Clove and Catskill, and local residents of Hanes Falls, East Jewett, Tannersville, and Hunter, as well as a number of local organizations The idea originated with an anonymous resident of Twilight Park and met with hearty approval. The gift was made purely as an expression of good-will which the community holds Dr Baldwin in, who has devoted thirty-two years to Mountain practice.

AT THE 130TH ANNUAL MEETING of the Medical Society of Greene county held at Walters' Hotel in Cairo on Oct. 13, the following officers were elected

President, Dr T. Earl McQuade, of Coxsackie, vice-president, Dr Alton B. Daley, of Athens, secretary, Dr William M. Rapp, of Catskill, treasurer, Dr Mahlon H. Atkinson, of Catskill; chairman of committee on public health, Dr M. K. Colle, of Catskill, chairman of committee on legislation, Dr P. G. Waller, of New Baltimore, delegate to State Medical Society, Dr Norman S. Cooper, of Athens

Dr Thomas Parks, of New York City, was the speaker of the evening The meeting was preceded by a dinner

Kings County

THE NEXT REGULAR monthly meeting of

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested.

Albany County

THE OCTOBER MEETING of the Medical Society of the County of Albany was held in the Auditorium of the Albany College of Pharmacy, October 28. The Scientific Program "Coronary Heart Disease," Vice-Presidential Address, Dr Charles A Perry

Bronx County

THE UROLOGIC STAFF of the Morrisania City Hospital will give the following lectures for the general practitioner of the Metropolitan area, who are invited to attend Time 3 to 4 P M

Nov 19, "Urogenital Tuberculosis," Dr John Duff

Dec 17, "Prostatic obstruction," Dr John J Roth.

Jan 21, 1937, "Treatment of gonorrhea in the male," Dr Terry M Townsend

Feb 18, "Hematuria," Dr John Duff

Mar 18, "Non-specific infection of the male genital tract," Dr John J Roth

Apr 15, "Stone in the urinary tract," Dr Terry M Townsend.

May 20, "Practical urological diagnosis and treatment," Dr John Duff

June 17, "Renal infection of non-calculous origin," Dr John J Roth

Broome County

THE BROOME COUNTY Medical Society met on Oct. 16 at the Binghamton City Hospital and listened to an address by A. H Aaron, MD, Professor of Gastro-intestinal Diseases, University of Buffalo, on "Diagnosis and Treatment of Common Gastro-intestinal Diseases"

OUR LADY OF LOURDES hospital medical staff announces completion of its reorganization, headed by Dr William A. Behan as president of the staff, with Dr Blinn A Buell as secretary, and the following new committees

Executive H I Johnston, John J Cunningham and Howard W Davis, credentials, S D Molyneaux, John D Bowen and Walter J Farrell, interne, George T Vogt, H P Griffin and C J Marshall, record Emil C Mrozek, John J Brick, I Smith and Hyman Snererson

Chemung County

GREAT INTEREST is evident throughout the State in the negotiations going on for determining public welfare medical and hospital costs. In Elmira the appointment

of a Medical Advisory Board to control hospitalization costs for public relief patients is announced by City Manager Hunter in a letter to Dr Arthur C Smith, president of the Chemung County Medical Society

The committee will consist of two city physicians, a physician each from the Arnot-Ogden and St. Joseph's Hospitals, Mrs Jane Watson, home relief director, two City Councilmen, and the City Manager

The letter to Doctor Smith

I spent the greater part of last week at a conference of New York State Commissioners of Public Welfare in Albany and was not surprised to learn that the general feeling throughout the state is that public welfare medical and hospital costs are entirely too high. In fact, the average in the state is less than the cost in Elmira and is still considered too high by the state officials

As you know, I have made every conscientious effort during the past three or four months to reduce the cost of this branch of welfare to the city and the taxpayers and we have had several conversations on this subject. It is recommended to me by the New York State Department of Welfare that some sort of medical advisory board be established in Elmira and conforming with this recommendation I am asking that you appoint a physician to this committee from the Arnot-Ogden and St. Joseph's Hospitals

The committee is to consist of Doctor Larson and Dr Creighton, the two city physicians, the two doctors which I am asking you to appoint, two members of the City Council, Mrs Watson, director of public welfare and myself

The intention of this committee is that we may, through our combined efforts and better knowledge of the situation, find and put in practice whatever methods can be devised for better service and lower costs and I will appreciate the co-operation of yourself and the Medical Society in this effort.

Delaware County

DR WILLIAM M THOMSON, of Delhi, Secretary, reports that the Delaware County Medical Society met at Stamford on Sept. 15. A resolution was moved by Dr Brittan and seconded by Dr Davidson that "a committee of two be appointed by the President of this Society to petition our County Board of Supervisors asking them to designate the Delaware County T B Sanatorium as a clearing station for all county T B cases, making it compulsory

that all County cases first be hospitalized in the County Hospital and then, if deemed advisable, they may be transferred to other hospitals" This resolution was carried and the president appointed Doctors Davidson and Brittan

The Economics Committee recommended that the society accept the fee schedule adopted by the Metropolitan area for compensation work and the recommendation was carried.

The guest speakers, Dr Marie P Warner and Dr Benjamin Warner, gave an enlightening discussion on contraception and its technic, illustrated by slides and moving pictures

Dr Thomas Parks, of New York City, was the speaker of the evening The meeting was preceded by a dinner

Kings County

THE NEXT REGULAR monthly meeting of

the Medical Society of the County of Kings will be held at the MacNaughton Auditorium, 1313 Bedford Ave., on Tuesday evening, Nov 17 The program

"Acute and Chronic Bacillary Dysentery, with Especial Reference to Chronic Distal Ileitis and Chronic Ulcerative Colitis", Joseph Felson, M.D., Bronx (Lantern Slides)

"Chronic Regional Ileitis and Coloileitis, from the Pathological and Surgical Point of View," Albert A Berg, M.D., Manhattan (Lantern Slides)

Also given at the MacNaughton Auditorium are the Friday Afternoon Lectures at 4 30 P M

November 20, Joseph C. Aub, M.D., Boston, "Clinical Aspects of the Normal and Disturbed Calcium Balance."

December 4, Harry Wessler, M.D., Manhattan, "Surgical Indications in Thoracic Disease."

December 11, Gregory Schwartzman, M.D., Manhattan, "The Role of Bacterial Reactivity in Infections and Anaphylactic Processes"

THE MATERNITY CENTER DIVISION of the Brooklyn Visiting Nurse Association has adopted a four-point program in the further advancement this year of its efforts to safeguard the health of mothers and new-born babies and to assist in the movement to reduce the maternity and infant mortality rate in Brooklyn Mrs Albert W Meisel, chairman of the division, announces

The four-point program is as follows

1 To assist the Committee on Maternal Welfare of the Medical Society of the County of Kings in the study of all maternal deaths as they occur in Brooklyn

2 To arrange groups in Brooklyn to be addressed by physicians on the subject, "What Constitutes Adequate Maternal Care."

3 To conduct classes giving instruction in pre-natal, infant and post-natal care to expectant mothers

4 To compile and maintain a current resource file on all maternity facilities in Brooklyn

Madison County

THE ANNUAL MEETING of the Madison County Medical Society was held at Hotel Oneida, in Oneida, on Oct. 27 The program "Appendicitis in Childhood," Dr C C Curtiss, Syracuse, N Y "Pernicious Anemia," Dr Ellery G Allen, Syracuse, N Y Illustrated by lantern slides and diagrams President's Address "Hematology," Dr R L Crockett, Director of Madison County Biological Laboratory, Oneida, N Y

An effort is being made to organize a Ladies Auxiliary

Monroe County

THE RISING PERIL OF THE drunken driver

was discussed before the Medical Society of the County of Monroe on Oct 13 by Dr Theron Wendell Kilmer, Hempstead police surgeon.

Declaring that "one of the greatest dangers on the highway is the drunken driver," Doctor Kilmer pointed out that state statistics show a 43 per cent increase in drunken drivers the first six months of 1936 over the same period in 1935

But how to tell when a driver is intoxicated is the problem that faces police officials, Doctor Kilmer continued "A driver who is but slightly drunk is as unfit to drive a car as one who is totally drunk," he insisted

"It is often a hard task for a physician to determine whether a person is drunk and no person, unless he be a physician, should be allowed to pass upon and render such an important decision," Doctor Kilmer asserted

"In some cities this is left entirely to the arresting officer This is wrong and gives neither the square deal The old saying that 'anyone can tell a drunk' is not true and if followed will lead only to a wrong conclusion"

Doctor Kilmer also cited the necessity for the examining physician's keeping a record, without which a defense attorney "makes the doctor feel very small" He urged the doctor to fill out a form card in the presence of the arresting officer and desk man at the police station He also urged that such records be preserved

"This card made out at the time of arrest," Doctor Kilmer pointed out, "while not admissible evidence at the trial, is used by the physician to refresh his memory When the attorney for the defense asks the doctor 'How do you know this man was drunk at the time?' the doctor replies that a person presenting the symptoms noted on the card is drunk"

Doctor Kilmer then showed and discussed the card used by the Hempstead police, a form which permits the examining physician to give in detail the symptoms noted when a driver is examined for intoxication.

He gave this warning

"Be careful! Do not let your municipality be sued for a large sum of money just because the suspect was pronounced drunk by the arresting officer The sure way of telling whether a person is drunk or not is to test the spinal fluid for alcohol This, of course, only can be done by a physician when a case is in the hospital"

"During the last month," Doctor Kilmer told his audience, "English physicians have been noting the effect of alcohol on the

driver of a car Results of their experiments show that in every case where a driver has been drinking the speed of the car invariably increases The judgment and co-ordination of the driver are greatly affected."

ROCHESTER ACADEMY OF MEDICINE has expressed its approval of the recently-adopted city ordinance muzzling unnecessary racket in the streets

Dr G Kirby Collier heads a committee of physicians which will co-operate with the Citizens' Committee of the Chamber of Commerce on Noise Abatement. Members are Doctors E J Avery, M A Barnard, L C Bohnton and G A Hilleman

The chamber plans to enlist the co-operation of automobilists and Parent-Teacher units throughout the city Henry Nicholson, member of the chamber committee, announced.

New York County

THE NEW YORK CITY Health Department has been furnishing the physicians free laboratory services for the diagnosis of syphilis and gonorrhea. It has also offered its personnel for consultation It now announces an additional important service made possible by Federal cooperation through the New York State Department of Health. Any physician may obtain free arsenicals and bismuth for a year of treatment in allotments of about four months at a time, and without regard to the economic status of the patients

This is done in order to secure a greater participation on the part of private physicians in the campaign against venereal disease. Application blanks for the drugs will be sent upon request by the Bureau of Social Hygiene of the Department of Health, 125 Worth Street

THERE HAS JUST BEEN inaugurated at the Meinhard Health Center, 131 East 101 Street, a program of public health instruction to be given jointly by the New York Medical College and the East Harlem Health District. This will soon be followed, says Commissioner John L Rice in *Neighborhood Health*, by the establishment of similar joint programs by the other New York City medical schools, namely, Columbia, (P & S), Cornell, New York University, (Bellevue), and Long Island Medical College. By means of this union of medical school and district health center, the students will observe at first hand community health work. They will also have an opportunity of personally taking part in this work Dr Rice adds that "This marks a long step forward in the teaching of preventive medicine."

Oneida County

MEMBERS OF THE Oneida County Medical Society were guests on Oct 13 at Broad-acres Sanatorium, where they had a business meeting after a turkey dinner

Dr Dan Mellen, Rome, conducted the meeting, at which Dr C H Baldwin read a paper on "Tuberculosis of the Bones and Joints" Dr A. R. Hatfield, Jr discussed the paper Dr J J Witt, Broad-acres, read a paper on "Tuberculosis in Children" and Dr William P Brown, heart and lung specialist of the State Department of Education, who stopped for the meeting while passing through Utica, discussed the subject, as did Dr T Wood Clarke. Dr F M Miller, Sr reported as chairman of the economics committee

At the annual meeting, January 12, officers will be elected and the president will deliver the address

SCIENTIFIC DISCUSSIONS occupied the attention of the Utica Academy of Medicine at a meeting in Hotel Utica on Oct. 15

Dr Donald Van Slyke, director of the Chemical Laboratory, Rockefeller Institute, spoke on "Tests of Renal Function." The discussion was led by Dr E G MacFarland and Dr R. C. Borst

Dr Oswald J McKendree, Utica State Hospital, presented a paper on "Congenital Syphilis in One of Two Identical Twins," and Dr H D Parkhurst opened the discussion.

The group adopted a new constitution, which is a condensed version of the former one. Dr E K. Reed, Rome, was accepted as a member Dr T Wood Clarke presided. About seventy-five physicians attended the meeting

Onondaga County

A COUNTRYWIDE CAMPAIGN to aid the reduction of maternal mortality is announced by Dr F J Schoeneck, chairman of the maternal welfare committee of the Onondaga Medical Society

The professional portion of the campaign will consist chiefly of a course of five sessions covering the newer developments in obstetrics and obstetrical care. A similar seminar will be conducted by the nurses' registry board for private nurses treating with the newer developments in obstetrical nursing

The lay portion of the program will open with a mass meeting early in January The meeting will be sponsored and arranged by the Women's Auxiliary of the Onondaga Medical Society, with representatives present from every social service and profes-

sional organization in the county. Members of the medical society will explain to the organization the part each individual must play in this campaign.

The county campaign is a part of the nationwide movement to improve the standards of maternity care in the United States.

THE SYRACUSE ACADEMY OF MEDICINE met at the University Club on October 20. The Scientific Program "Unusual Case of Jaundice," Dr G B Andrews, "The Significance of Low Marrow Reserve," Dr J Van Duyn 2nd, "Relation of Blood Pressure to Vomiting in Spinal Anesthesia," Dr J C Frey.

DR. FRANK REYNOLDS, of Syracuse, retiring from medical practice after nearly fifty years, and Mrs Reynolds, were given a testimonial dinner by staff members of Crouse-Irving Hospital on Oct. 15. Dr Reynolds has been associated with the hospital since its founding in 1912. Toastmaster for the dinner, at which sixty-four persons were present, was Dr H O Brust, chief of the hospital surgical department.

PARTICIPATION IN A maternal welfare mass meeting to be arranged for early in January was discussed at a meeting of the Women's Auxiliary to the Onondaga County Medical Society on Oct 16 at Hotel Onondaga.

Speakers included Mrs John L Bauer of Brooklyn, president of the State Auxiliary, and Dr O W H Mitchell of Syracuse. Twenty Auburn women, members of the Cayuga County unit, attended the luncheon and meeting.

Mrs Bauer came to Syracuse from Suffolk County, where she has been organizing an auxiliary. She is carrying on similar work in Madison County and will also visit Oneida and Monroe Counties in her organization work.

Orange County

DR. LESTER HOWARD MCALLISTER, physician in Port Jervis since 1910, died at his home Oct. 17. He was graduated from Bellevue Medical College in 1908, and during the World War served in the Medical Corps of the Army at Fort Sam Houston, Tex., and later overseas as regimental surgeon of the 56th Pioneer Infantry. He was discharged from the service in June 1919, at Camp Upton. He was a member of the American Legion, several fraternal and medical societies and had served as a member of the Port Jervis Board of Education. He was fifty-three.

Orleans County

DR. FREEMONT W SCOTT, eighty, dean of Orleans County physicians, died on Oct.

19 at the Medina Memorial Hospital where he had gone earlier in the day to pay a social call. Dr Scott had been in ill health for the past few years but had recently been able to be about.

A few years ago Dr Scott celebrated his fiftieth year as a practicing physician and the occasion was observed by the Orleans County Medical Association, of which he was a past member. He was also an honorary member of the Medina Memorial Hospital staff.

Queens County

THE ANNUAL MEETING of the Medical Society of the County of Queens, with election of officers and annual reports, will be held on Nov 24 at 8 30 P M. There will be remarks by Mrs Irving Ponemon, President, Woman's Auxiliary to the Medical Society of the County of Queens, Inc., and an address by the President, James M Dobbins, M D.

Rensselaer County

THE RENSSELAER COUNTY Medical Society, at its meeting on Oct. 13, listened to a paper by Dr Robert A. Robinson of Albany, whose practice is limited to oral surgery. He spoke on "The Physician as a Dentist Sees Him." The second paper was read by Dr James H Donnelly, who dealt with "Comparisons of Electric Currents." He cited several interesting cases in which physiotherapy had been used and stressed the importance of the various modalities.

At the following meeting, on Nov 10, the papers that were read included "Carcinoma of the Colon," Dr Eugene F Connally, "Diagnosis of Chronic Infections of the Tonsils in Relation to Indications for Operation in Cases of Focal Infection," Dr Irwin Johnston, and "Chronic Osteomyelitis," Dr Leo S Weinstein.

It is expected that Dr George W Crile, of the Cleveland Clinic, will be present at the annual meeting in December.

A PLEA TO PARENTS to co-operate in continuing for Troy its remarkable record of six years without a single case of diphtheria is made by Dr Charles A Birmingham, city health officer.

In his statement Dr Birmingham calls attention to the fact that fall and winter weather is most favorable for the contraction of diphtheria and that parents should forestall the possibility of their children catching the disease by having them inoculated by their family doctor.

Richmond County

DR. EUGENE J. CALLAHAN, sixty-five, a practicing physician on Staten Island for forty-two years, died on Oct. 1 following a heart attack at the Grasmere Lodge, S. I. He lived at 19 Dongan St., West New Brighton.

Dr. Callahan was one of the founders of St. Vincent's Hospital in West New Brighton and was instrumental in the establishment of the first island-wide ambulance service. He practiced in Manhattan for two years before settling on Staten Island. He attended Manhattan College and was graduated from the New York University School of Medicine in 1894.

Dr. Callahan was a member of the Knights of Columbus and a director of the West New Brighton National Bank.

Rockland County

DR. ISRAEL S. WECHSLER, professor of neurology, Columbia University, was guest speaker at the Fall meeting of the Medical Society of the County of Rockland, held in Franklin Hall, Letchworth Village, on Oct. 14.

Dr. Wechsler gave an instructive talk on "Neuritis, Etiology and Management" before a group of society members and their guests following a brief business session at which arrangements were made to hold an annual meeting and banquet in December.

Mrs. Edward A. Flemming, organization chairman of the Woman's Auxiliary to the Medical Society of the State of New York, addressed the society on the formation of an auxiliary in Rockland County to be composed of the wives, daughters, and sisters of the physicians.

Saratoga County

DR. MALCOLM MAGOVERN of Saratoga Springs, Secretary, reports that the annual meeting of the Saratoga County Medical Society was held at the Metropolitan Sanitarium, Mt. McGregor, October 14. Election of officers was the chief business of the day. Those elected for the following year are Dr. W. S. McClellan, President, Dr. R. B. Post, Vice-president, Dr. M. J. Magovern, Secretary, Dr. W. J. Maby, Treasurer, Dr. G. S. Towne, Delegate and Dr. J. R. MacElroy, Alternate, Censors Dr. F. J. Sherman, Dr. A. Johnson, Dr. G. F. Goodfellow.

Dr. Burke Diefendorf, Glens Falls, district health officer for Warren, Washington, and Saratoga counties, told of the work of the public health nurse.

Tompkins County

THE REGULAR MEETING of the Medical Society of the County of Tompkins for October was held October 20, at the Tompkins County Memorial Hospital. Aside from routine business, three new members were admitted and the question of the formation of a Woman's Auxiliary to the Society was laid on the table for possible future consideration. After the business session, Dr. Anton W. Sohrweide of Syracuse and Ithaca gave an illustrated lecture on "The Diagnosis and Treatment of Some of the Commoner Skin Lesions."

THE NOVEMBER MEETING of the Medical Society of the County of Tompkins will be a combined one. On November 19, at 8:30 P. M. at the Memorial Hospital, Dr. Terry M. Townsend and Mr. Dwight Anderson of the Public Relations Bureau of the Medical Society of the State of New York will discuss various phases of the work of the Bureau. The Medical Societies of the Counties of Tioga, Schuyler, Oswego and Chemung have consented to send delegations to this meeting and it is expected that a large gathering will listen to this important and valuable discussion.

Warren County

ABOUT 150 PHYSICIANS and surgeons of Glens Falls and vicinity attended the dinner-meeting of the Glens Falls Academy of Medicine on Oct. 16 and heard Dr. E. B. Freeman of Baltimore discuss "The Practical Value of Special Diagnostic Methods in the Study of Digestive Diseases."

Yates County

THE DINNER-MEETING of the Yates County Medical Society on Oct. 12 was devoted to a discussion of the medical and hospital care of welfare cases. The meeting was attended by members of the society, Yates County Board of Supervisors, board of managers of Soldiers and Sailors Memorial Hospital and welfare officers of Yates County.

John T. Bishop, chairman of the Board of Supervisors, spoke of the position of the board in protecting the interests of taxpayers.

The physicians' side of the matter was presented by Dr. Allan W. Holmes, of Foster-Hatch Medical Group, who stated that most physicians are giving a great deal of medical care to relief cases without receiving any remuneration. He said that the doctors in Yates County gave in services and supplies much more than the taxpayers were ever called upon to pay them for services rendered.

sional organization in the county. Members of the medical society will explain to the organization the part each individual must play in this campaign.

The county campaign is a part of the nationwide movement to improve the standards of maternity care in the United States.

THE SYRACUSE ACADEMY OF MEDICINE met at the University Club on October 20. The Scientific Program "Unusual Case of Jaundice," Dr G B Andrews, "The Significance of Low Marrow Reserve," Dr J Van Duyn 2nd, "Relation of Blood Pressure to Vomiting in Spinal Anesthesia," Dr J C Frey

DR FRANK REYNOLDS, of Syracuse, retiring from medical practice after nearly fifty years, and Mrs Reynolds, were given a testimonial dinner by staff members of Crouse-Irving Hospital on Oct. 15. Dr Reynolds has been associated with the hospital since its founding in 1912. Toastmaster for the dinner, at which sixty-four persons were present, was Dr H. O. Brust, chief of the hospital surgical department.

PARTICIPATION IN A maternal welfare mass meeting to be arranged for early in January was discussed at a meeting of the Women's Auxiliary to the Onondaga County Medical Society on Oct. 16 at Hotel Onondaga.

Speakers included Mrs John L. Bauer of Brooklyn, president of the State Auxiliary, and Dr O W H Mitchell of Syracuse. Twenty Auburn women, members of the Cayuga County unit, attended the luncheon and meeting.

Mrs Bauer came to Syracuse from Suffolk County, where she has been organizing an auxiliary. She is carrying on similar work in Madison County and will also visit Oneida and Monroe Counties in her organization work.

It is expected that Dr George W. Crile, of the Cleveland Clinic, will be present at the annual meeting in December.

A PLEA TO PARENTS to co-operate in continuing for Troy its remarkable record of six years without a single case of diphtheria is made by Dr Charles A. Birmingham, city health officer.

In his statement Dr Birmingham calls attention to the fact that fall and winter weather is most favorable for the contraction of diphtheria and that parents should forestall the possibility of their children catching the disease by having them inoculated by their family doctor.

and the purpose of it. I say it is radically unfair to a doctor to have a demonstration sought to be made here under those circumstances.

Mr B Your Honor, if there is anything unfair with Dr M., I want to know where it is. I have had lots of experience with him.

The Witness Ditto.

Mr A. We ask an exception, and that the jury be instructed to disregard that very nasty statement just made by counsel.

Mr B I have got a right to answer that gentleman when he makes a proposition of that kind.

Mr A. I ask that the jury be instructed—

The Court These controversies between the lawyers and the witness are something not evidence in the case. The jury will disregard it. Go ahead.

The trial terminated in a verdict in favor of the plaintiff, and from the judgment an appeal was taken. The principal contention urged on behalf of the defendants was that the Court had abused its discretion in permitting the demonstration. It was argued that the attempt to raise her arm amounted to a physical combat in the courtroom, the plaintiff deliberately resisting the doctor and crying out with pain which may have been entirely pretended. Such a performance, it was claimed, necessarily aroused the sympathy of the jury toward Mrs P.

The Appellate Court determined that the Trial Court had in fact committed prejudicial error in ruling as it had, and directed a new trial of the case. In so deciding the Court said in its opinion:

While the Trial Court may, in its discretion, permit a plaintiff in a personal injury case to exhibit a limb that has been injured, where there is no wound and no reason for inciting the sympathy of the jury, we think it was an abuse of discretion for the Trial Court to permit a demonstration or experiment of raising the plaintiff's arm and permitting the plaintiff to cry out in pain. The condition of plaintiff's arm and shoulder had all been testified to, and both the plaintiff and Dr M. indicated that it would be painful for her to raise her arm, and counsel must have known that for the doctor to raise plaintiff's arm would give her pain and it would naturally be expected that plaintiff would cry out or complain of the pain.

Without suggesting that plaintiff was not acting in good faith, such a proceeding opens the door for simulation and has a tendency to arouse the sympathy of the jury for the plaintiff and possibly resentment against the defendant, and we think it was an abuse of discretion and error.

Fecal Concretion Confused with Rubber Tube

A physician who specialized in general surgery was called to the home of a woman forty-five years of age, complaining of ab-

dominal pains. He diagnosed the condition as acute appendicitis and arranged for her immediate entry into a hospital. Upon operation the doctor found a condition of ruptured appendicitis with spreading peritonitis and in closing the wound he left a rubber dam drain in the wound and packed the wound wide open with iodoform gauze. The patient's condition slowly improved and after a stormy course in the hospital she was sent home about two months after the operation. At that time the incision had not closed completely and there was slight drainage from the opening.

After her discharge from the hospital the patient returned to the surgeon at his office for dressings and examination and he treated her from time to time, a small sinus remaining open. The patient, after some time had elapsed, went away for a summer vacation and the doctor did not see her for a period of several months. She returned to his office in the fall and again he found that she had a small open sinus at the point of the old incision. The doctor at the time advised further treatment to promote healing of the sinus but she never made the necessary arrangements to undergo such treatment. The next he heard from the patient was when she came in during the early winter with the wound completely healed. At that time she accused the doctor with having left a piece of rubber tube within her body and made the claim that said rubber tube had come out through the sinus, that as soon as the same had so come out the wound had promptly healed.

Thereafter the patient instituted a malpractice action against the surgeon based upon the said theory of what had happened, it being alleged on behalf of the plaintiff that the foreign substance in question was a rubber tube or drain. Before the case was reached for trial a physical examination of the plaintiff was arranged and a disinterested surgeon at the time of the examination, examined the plaintiff herself and also made an examination of the alleged foreign body. It was his opinion after such examination that the claimed foreign body was not in fact made of rubber but that it was a fecal concretion which had in the ordinary course of things worked its way to the surface. The substance was hard and round about the size of a pea. The plaintiff and her attorneys apparently never learned the true nature of the substance until a day or so before the trial when a pathologist was called upon by them to make an examination of the substance and he reported that it was composed principally of calcium and was in all probability a fecolith.

During the course of trial, plaintiff's

Evidence—Demonstration by Medical Witness

When a physician makes a physical examination of an injured person who is a party to a negligence action and subsequently gets on the witness stand to describe his findings, he may encounter various difficulties in the course of his testimony. In a case* just decided by the Courts of one of the Pacific Coast States, a ruling was made upon the extent to which a physician could be called upon to demonstrate his findings before a jury. The situation which developed during the trial of that case was one which should be of interest to every physician who in the course of his practice goes into Court to describe physical conditions found by him in the course of previous examinations or treatment.

The case was one in which two automobiles had collided at night at an intersection, and the occupants of one of the cars had received injuries. The plaintiff, a Mrs. P, brought suit against the owner and operator of the car which she claimed was in the wrong, and she charged in her complaint that she had sustained a permanently painful injury to her right shoulder which prevented her from raising her arm. The inability to raise the arm she alleged was permanent.

It appeared from the testimony upon the trial that x-rays to ascertain the nature of the injuries had been negative. At the request of the attorney for the defendants a certain Dr. M. had examined Mrs. P. shortly before the case went to trial. He was called as a witness and stated that he found that the plaintiff experienced considerable difficulty in raising her arm above a horizontal position and in moving it backwards. He described how when he had examined her he had taken hold of the arm and had been able to raise it, although she said at the time that that part of the examination hurt her. The crux of his testimony was when on cross-examination the Court, over objection of defendants' counsel, permitted the doctor to be required to demonstrate before the jury the raising of her arm. The following is a transcript of part of the record in connection with such cross-examination.

Q And now her shoulder and arm, you claim the arm can go up? A I claim I could put it up, and she wouldn't put it up herself, and said

she couldn't do it.

Q You could take by physical force and shove the arm up? A Yes, sir.

Q Now, the patient says she couldn't raise it? A Yes, sir.

Q Did you ever have that happen before in your practice? A Yes, sir.

Q Where there could be no physical reason for a practically certain, apparent result? A No, that is making it a little too strong, Mr. B.

Q Then change it to fit your particular experience? A I could cite personal experiences, a few years ago I had a serious condition of my own shoulder, came from infection, and mine wouldn't go up all winter—wasn't due to accident.

Q Doctor, under the same situation, yours wouldn't go up, and you couldn't put it up?

A No, mine wouldn't go up and I couldn't put it up.

Q Could anybody else put it up? A. I wouldn't let them, no.

Q Let the lady stand up, and you show this jury just what you—let me have your coat (the plaintiff stands up before the jury and removes coat). Now, doctor, will you just come down here, and before the jury show just what the woman can do herself, and what is necessary. A (interruption) Well, she can tell that without my being there.

Q You show the jury what you did, to satisfy yourself.

Mr. A. (defendant's counsel) If the Court please, I object to this demonstration, it has only one purpose, that is perfectly obvious to Your Honor. The plaintiff herself has testified that the arm could be put up there, but she couldn't put it up. The doctor has so testified. This demonstration has no purpose except to try to make an impression here—to create prejudice in the case. I certainly think it is highly prejudicial.

Mr. B. If your Honor please—

The Court. It is part of the cross-examination.

Mr. A. I grant you it is part of the cross-examination, Your Honor, but it serves no useful purpose in the case for the lady to wince here and show pain while the doctor is manipulating her arm. I don't see what purpose that serves, the doctor does not say that she has not pain under those circumstances.

The Court. He may go ahead.

Q (by Mr. B.) Doctor, show the jury just how you examined that arm. (The doctor descends from the witness stand and demonstrates before the jury the raising of plaintiff's arm at which the plaintiff cries out.)

The Witness. She is deliberately holding back today, in addition to what she did in my office. I had no difficulty then.

Mr. A. Your Honor sees the object of this,

* *Peters v. Hockley*, 53 Pac. 2nd 1059

Across the Desk

The New Drive to Stamp Out Syphilis

AN INCIDENT WAS RELATED in these pages not long ago in which four members of a family of six were innocently infected with syphilis by a wayward daughter who loaned her chewing gum to the other children and kindly chewed bread till it was soft for baby. Baby infected mother, who infected father, and there was almost a divorce in the family until the wise physician investigated, found the truth, and started treatments for recovery.

More than fifty per cent of the cases of syphilis, indeed, are said to be contracted innocently. Seventeen cases in this state were recently traced to a high school party where kissing games were played. Infection has been communicated in the rough scrimmage of football. Drinking from contaminated cups and glasses is undoubtedly a fruitful source of contagion.

Bring it Out into the Open

What this means is that syphilis is no longer a disease to be hidden away and covered up, like a guilty secret, and when the public is convinced of that fact, then we shall have it out in the open where we can wage a fair fight, and its doom will be certain. As things stand now, its prevalence is little short of appalling. Experts figure that one in ten of our population is afflicted with *Treponema pallidum*, the colorless little corkscrew devil that causes syphilis and all its tragic sequelae. Syphilis is said to kill three times as many as tuberculosis in our land every year, with a toll of 100,000, not counting the many heart fatalities due primarily to it. One in every ten patients in the mental hospitals owes his trouble to its insidious devastation of the system. A sure sign of its growing seriousness is the increasing number of papers and earnestness of discussion about it at the medical meetings and in the pages of the medical journals.

See What Others are Doing

Yet we have only to look across the Atlantic to see countries far less rich and powerful than our own which have practically conquered this dread plague. With

great wisdom, New York City appointed a Commission to investigate the prevention and control of syphilis and gonorrhea in the Scandinavian countries and in Great Britain, and it has now made its report. The Commission is made up of Dr. John L. Rice, Commissioner of Health of the City of New York, Dr. David J. Kaliski, representative of the Five Counties Medical Society of Greater New York City, Dr. Thomas P. Farmer, representative of

THE NEW YORK CITY COMMISSION

Dr. David J. Kaliski, Dr. Thomas Parran, Jr., Dr. Thomas P. Farmer, and Dr. John L. Rice

the State Medical Society, and Dr. Thomas Parran, Jr., Surgeon General of the U. S. Public Health Service, formerly Commissioner of Health of this State, who accompanied the Commission and participated in its studies. The report was compiled by Dr. Charles Walter Clarke, Director of the Bureau of Social Hygiene of the New York City Department of Health. Clearly nothing could be more authoritative.*

Different Tactics, Different Results

The briefest glance at the report reveals a striking difference between the Scandinavian and the British treatment of syphilis, and shows perhaps why the Scandinavians have had so much better success. In Great

* Copies of the complete report, which was published as a supplement to the *American Journal of Syphilis, Gonorrhea, and Venereal Diseases*, July, 1936, may be obtained upon request from the Division of Social Hygiene, New York State Department of Health, Albany.

attorneys changed from the theory that the defendant had negligently permitted a piece of rubber to remain in the plaintiff's body to a charge that the defendant had been negligent in failing to find the piece of fecal concretion on certain occasions when the wound was probed by him, and that proper practice would have required him to have managed in some manner to remove the fecal concretion months before it spontaneously came to the surface. The defendant and his witnesses, however, testified that the defendant followed good judgment and proper practice throughout his care of the case. At the close of all the testimony the Court directed judgment in favor of the defendant thereby exonerating him of the charges of malpractice.

Treatment of Infected Thigh

A physician was called to attend a five year old child and on examination found that she was suffering from an infection of the thigh. He arranged to have her promptly put in a hospital and there under a general anesthesia opened up the infected area releasing pus and established drainage. The following day the child was in satisfactory condition to be taken home and the doctor continued seeing the case from time to time.

About two months after the operation the child was brought to the doctor and it was explained that she had again fallen and injured the same leg at the site of the old scar. Examination showed that the old wound was lacerated. He dressed the lacerations and gave a prescription for syrup-iodide of iron and Fowler's solution by mouth. The doctor continued the care of the case, redressing the wound, and while the patient was so under his care she developed fungus growths over the body. He applied wet dressings for the purpose of treating said growths but the child did not improve and the doctor arranged that the child again enter a hospital. However, while at the said hospital the patient went under the care of another physician.

When the doctor instituted an action

against the parents of the child for the purpose of endeavoring to collect his fee for professional services rendered, a counterclaim was interposed in which the charge was made that the treatment which the defendant had rendered had been the cause of the development of the fungus growth.

The case was tried before a Judge and Jury and the defendants were unable to establish that the treatment which the doctor had administered to the child had been the cause of the complications. Therefore, at the close of all the testimony the counterclaim was dismissed upon motion and a directed verdict in favor of the doctor was granted for the full amount of his bill.

Accident During Application of Acid

A six year old child was brought to the office of a general practitioner by his mother, who complained that the boy was suffering from a rash. The doctor examined him and found his condition to be molluscum contagiosum, which particularly affected his chest, abdominal wall, one thigh, and his face. The doctor proceeded to curette the lesions on the body, using a skin curette and that treatment was carried out with satisfactory results.

The doctor then undertook to apply trichloroacetic acid to the lesions on the child's face. He used a wooden applicator tipped with cotton and just as he was about to apply the acid the child's mother loosened her hold on the child and he suddenly raised up and his nose came in contact with the acid on the end of the applicator. Although the doctor applied bicarbonate of soda immediately a superficial burn developed which the doctor treated and the child was brought in three days later. The patient was never brought back to the doctor for any further treatment.

Some time later a malpractice action was brought against the doctor charging him with negligence in treating the child. Plaintiff's attorney, however, failed to place the case on the calendar for trial and in due time the action was dismissed upon defendant's motion.

At the request of the American Society for the Control of Cancer, a fifteen minute program has been arranged through WJZ and the blue network of the National Broadcasting Co., November 20, 3 00 P M.

The speakers will be Mrs. Grace Morrison Poole, Chief Advisor to the Women's Field Army and Dr. C. C. Little, Manag-

ing Director of the American Society for the Control of Cancer.

This program will be given in dialogue. It has been scheduled by the New York Tuberculosis and Health Association under the auspices of the Medical Information Bureau of The New York Academy of Medicine.

order to enable private physicians to care for a larger number of patients having syphilis, especially that large body of individuals who cannot pay the full regular fee, the Department of Health plans as soon as possible to provide neoarsphenamine, bismuth or mercury in amounts sufficient for one year of the treatment in accordance with modern therapeutic methods. These drugs should be supplied free upon request without distinction as to the patient's ability to pay the physician a full fee or any fee for his service. * * * * Because the funds when available for this purpose are expected for the present to be limited, drugs will be provided to private practitioners only for the treatment of early syphilis, syphilis in pregnancy, and congenital syphilis. Later it is hoped that the same assistance may be extended to all cases of syphilis found under private medical care."

Physicians will be aided by the Health Department to find the source of infection in each case, a plan that is proving encouragingly successful. Every victim of syphilis or gonorrhea, too, is given a pamphlet of instruction with regard to his infection and the protection of contacts. Doctors are urged to cooperate by reporting every case.

"We cannot transport to America any European plan, successful as it may have been abroad," remarked Dr Clarke, who compiled the report on the Scandinavian and British plans. "We must draw up our own blue-prints and build our own public health

structure." Sweden and Denmark may afford us useful hints, and show us fundamental principles. "But what we need for New York, we contend, is a New York Plan—one that is based on the essential medical data, but nicely adapted to our par-

Cases of acquired syphilis per 100,000 population in Copenhagen and other parts of Denmark, 1877-1933

ticular social and medical institutions and conditions * * * * Without expecting miracles, but anticipating that the changes will be indicated as we progress, we believe that a start in the right direction has been made, and that, with the coöperation of our colleagues in private practice and in hospitals, we will, if we persevere, see a radical reduction in the prevalence of syphilis and in the disasters which it causes"

THE RACE OF DOCTORS AND PATIENTS

In proportion to the total population, there are fewer physicians practicing in the United States, today, than there were twenty years ago, although in actual numbers there are now about 20,000 more legally qualified physicians in the country than were registered in 1916. In that year there was one physician for every 694 persons in the entire population, in 1936 there was one

doctor for every 778 persons, according to figures in the *Statistical Bulletin* of the Metropolitan Life Insurance Company. In New York State, however, an opposite trend appears. In 1916 there was one doctor for every 633 persons, and, in 1936 one for every 539. In the borough of Manhattan there are only 287 persons per physician.

WHY IS IT?

The surgeon will write a prescription
In scrawlings and symbols most weird,
So even the druggist looks puzzled
And mutters down into his beard
But when the physician is ready

To tell the amount of his bill
He types out a neat little statement
So certain it gives one a chill

—James A. Sanaker in *Country Gentleman*

Britain its prevalence has been cut to one-half what it was in 1920, or 20,692 cases treated in 1934 as against 42,805 in 1920. In the three Scandinavian countries, however, the authorities were notified of less than 1600 cases in 1933, in a population of 13,700,000. At that figure, it can be said that it has ceased to be a problem.

The difference between the British and the Scandinavian tactics is that in Great Britain no legal control over the patient is exercised, entire dependence being placed upon free clinic treatment for all, while in Scandinavia all sources of infection are ascertained, and treatment, while gratis, is compulsory. In Copenhagen the results seem almost miraculous. From 1919 to 1933 the number of cases of acquired syphilis in that city dropped from 3000 yearly to less than 200, "an actual decrease in cases which, it is stated, cannot be equalled by any other metropolis in the world."

Sweden, as a whole, however, shows better results than Denmark. In Sweden "syphilis has decreased in prevalence to the point where one may refer to it as almost a rare disease, there having been reported in 1934 only one new case in 14,000 population, a case rate of seven per 100,000 population, as compared with a case rate of twenty per 100,000 in Denmark."

How Sweden Does it

Sweden's plan, then, is worth our attention. It requires that all persons having syphilis, gonorrhea, or soft chancre in an infectious stage must submit to treatment. If any patient fails or refuses, he is hailed to the hospital by the police, but this is seldom necessary. Treatment is free, and the cost is borne by the state. Medical practitioners must report every case, and discover and report the sources of infection, a point strongly insisted upon. The precipitous fall of syphilis noted above has followed the adoption of this plan in Sweden and very similar programs in Denmark and Norway. Several causes are given credit. "First and foremost are believed to be the basic scientific fact that treatment renders syphilis non-infectious and the fact that in all of these countries diagnosis and treatments are free, accessible, and generally good." It must be noted that the conquest of syphilis has not been duplicated in the battle with gonorrhea, perhaps because it is not so easily made non-infectious.

The question arises, then, whether we can follow Scandinavia's example, or must be content with a more voluntary and ineffective control like Great Britain's. In such a comparison, remarks the Commission, "our policy and practices more nearly resemble those of the Scandinavian countries, for we have all the legal powers of those countries to deal with syphilis and gonorrhea as communicable diseases." True, we have not facilities for treatment free to all, but "the critical problem in America may be said to be that of overcoming these obstacles, and bringing all infectious cases of syphilis and gonorrhea, regardless of economic status, under medical care."

New York Starting a Big Push

New York City is starting a vigorous offensive, to judge from an address delivered a few days ago by Dr. Clarke before the annual convention of New York State Nurses at the Hotel Pennsylvania. There are now 378,000 cases of syphilis in the city, he said, and each week about 1000 newly diagnosed cases are reported to the Health Department. His estimate is that about five per cent of the population is affected which seems more credible, and is certainly more comfortable, than the ten per cent estimate of other statisticians. He appealed, in his address, to the 14,000 licensed physicians of the city to act as "shock troops" in the battle with this scourge, for "private practitioners collectively see or have the opportunity to see more cases of syphilis than all the institutions combined. More general use of modern diagnostic procedure would lead to the discovery of many thousands more cases of syphilis and the treatment of these cases to the enormous benefit of the public health and the profit of the profession."

"Do we know enough about syphilis to eradicate it?" he asked, and "if so, can our knowledge be applied practically?" "I believe," he averred, "the answer to both of these questions is in the affirmative."

Its five-point Plan

The program of New York City is of interest to the entire state, to follow New York's example, or to better it. In this program, the Health Department, first of all, offers to perform serologic tests for syphilis without charge. Some 215,000 specimens were tested last year. Next, "in

Detachment of the Retina Operative Technique in Treatment. By J Cole Marshall, M D Octavo of 80 pages, illustrated New York, Oxford University Press 1936 Cloth, \$2 75

This small book of 80 pages is essentially a bird's eye view of the development of the operative technic employed in the cure of retinal detachment in the past six years. As an Englishman the clinics on the Continent, in which so much of the pioneer work has been done, have been readily accessible to him. So he has thus been fortunate in seeing for himself the work of those with whose written descriptions most of us in this country must be content. In this way he has obtained first hand information from Gonnin, Safar, Weve, Vogt, Larsson, etc.

He gives a brief resume of the history and general examination in a case of attachment, and a more detailed description of the important matter of locating and localizing the retinal tear, with ocular measurements, special charts, etc.

Thermopuncture is fairly fully described, Guist's chemical cauterization more briefly, and most fully the various diathermy puncture methods, as well as the surface coagulation of Weve and Larsson. A point of especial interest is the fact that in Weve's operating theater every one wears black and all towels, etc. are black, to facilitate ophthalmoscopic observance in the progress of the operation.

The special apparatus and instruments devised and used by various surgeons are mentioned and many of them pictured. The closing chapter is a short description of the technic of electrolysis for the cure of this affection, as advocated by Vogt and by von Szily.

Throughout, one is struck anew by the need for careful, painstaking and thorough methods in the diagnosis, analysis, localization and operative technic in the attempt to cure this serious affection of detachment of the retina.

E. CLIFFORD PLACE

Basal Metabolism in Health and Disease. By Eugene R. DuBois, M D Third edition Octavo of 494 pages, illustrated Philadelphia, Lea & Febiger 1936 Cloth, \$5 00

The third edition of this work by one who may proudly trace his descent from Graham Lusk to Lavoisier, again brings to the medical profession a clear and simple explanation of the physiology of metabolism and its derangement in abnormal and pathological states. The essential processes are adequately discussed and controversial subjects are presented in a logical and entirely impersonal manner. The chapters on sur-

face area and normal standards have been largely rewritten in the light of recent contributions, and the suggestion advanced that the normal standards may soon undergo change. A chapter on the mechanism of the loss of heat from the body has been added. Other additions are a section on tissue metabolism, discussion of the etiology of thyroid disease, a section on creatin metabolism, and a presentation of the subject of thyroid ablation for cardiac disease.

This book should be added to the library of every practitioner of medicine.

CHARLES S BYRON

Medical History of Contraception. By Norman E. Himes, Ph.D Octavo of 521 pages Baltimore, Williams & Wilkins Company 1936 Cloth, \$7 00

The average person probably believes that birth control is of very recent origin. Dr Himes shows us that this belief is entirely wrong. His book teaches us that contraceptives have been employed from the very early ages.

Perhaps one of the most striking features of this first thorough study of the subject, is that ancients and moderns both strive to control fertility by artificial means. It has long been known that the ancients had a horror of sterility, but it is not common knowledge, that they attempted to limit an excess of progeny.

Dr Himes' study of the subject has been most exhaustive, and his book is of outstanding interest from the medical, sociological, and historical viewpoints.

W SIDNEY SMITH

An Introduction to Surgery. By Rutherford Morison, M D and Charles F M Saint, M D Third edition Octavo of 367 pages, illustrated Baltimore, William Wood & Company 1935 Cloth, \$5 00

This is the third edition of a volume that has been quite popular in some of the British medical schools. Both authors are teachers of surgery and have incorporated in this volume the general principles of surgery with drawings and actual pictures.

The various subjects are treated in a didactic and elemental manner that makes the book essentially one for the undergraduate student of surgery.

An attempt is made throughout the volume to simplify and portray the very basic principles of surgery. Surgical conditions, such as shock, hemorrhage, inflammation, etc. are discussed in a simple manner. The authors emphasize for the student the importance of appreciating the natural resources that the patient can produce in a cure of the various surgical conditions and cite case histories as illustrations.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWS

An Index of Differential Diagnosis of Main Symptoms by Various Writers Edited by Herbert French, M D Fifth edition Quarto of 1145 pages, illustrated. Baltimore, William Wood & Company 1936 Cloth, \$16 00

When one reads the publisher's advertisements, there is a tendency to resist the statements set forth, but as regards this book, they may be accepted without reservation. The "most valuable single volume in all Medical Literature," is powerful praise, but in the opinion of the reviewer, is justified in this case.

This edition appears seven years after the fourth and has the same general arrangement, the articles on the various symptoms

being placed alphabetically. The methods of distinguishing between the various diseases in which each symptom may be observed, are described in detail and the general index at the end, of over 200 pages, is a remarkable achievement giving 90,000 references to symptoms.

The illustrations are so excellent that one may sometimes make a diagnosis in an unusual condition unobserved before by the reader. There have been other books following a similar arrangement, but this one is in a class by itself. It is indeed as Richard C Cabot states, "altogether a masterpiece."

W E. McCOLLUM

Glandular Physiology and Therapy A Symposium Prepared Under the Auspices of the Council on Pharmacy and Chemistry of the American Medical Association. Octavo of 528 pages. Chicago, American Medical Association. 1935 Cloth, \$2 50

A series of articles published in the *Journal of the A.M.A.* last year are grouped together in this volume. Intended for the use of the general practitioner, this symposium falls considerably short of its purpose as a guide in the recognition of endocrine disorders and as a help in the selection of appropriate therapeutic procedures. It is of value only to those who seek condensed information of endocrine physiology with references to the most important contributions in the field of glandular research. Most of the chapters are ably written by recognized authorities of the subject matter, others, particularly the chapter on the adrenal medulla, are singularly one-sided and weak.

M. A. GOLDZIEHER

Time of Ovulation in Women. A Study of the Fertile Period in the Menstrual Cycle. By Carl G. Hartman. Octavo of 226 pages, illustrated. Baltimore, Williams & Wilkins Company. 1936 Cloth, \$3 00

Endorsed by the opinion of others, the author has presented, in this small volume, a sound survey of the present knowledge of the subject. His reputation in the field of research is well known and the interest with which he draws his conclusions is outstanding. The text is easily read and the material is presented in an interesting manner.

More and more the physician is called upon in this day to impart to patients the knowledge of the so-called "safe period." It is well that he substantiate his understanding of the subject by details of the facts contained in this volume.

As to his own opinion on the subject, the author tritely suggests in his closing paragraph—"the opponents of the Safe Period are more and more placed on the defensive as new facts accumulate."

WILLIAM C. MEAGHER

The Adrenals. By Arthur Grollman, M.D. Octavo of 410 pages, illustrated. Baltimore, The Williams & Wilkins Company. 1936 Cloth, \$5 00

The keen interest aroused by the discovery of the cortical hormone and the increasing clinical significance of adrenal physiology justifies the publication of this learned and well written monograph. It is unfortunate, however, that the author—an eminent pharmacologist—had to deal with questions pertaining to pathology and clinical medicine with which he had apparently no personal contact. Hence many statements

are based on second-hand information. Other important points are ignored, especially when at variance with the author's personal views. Grollman's concept of the tripartite nature of the adrenal, and of his "androgenic" tissue are interesting hypotheses at best, and should not have been presented with such certainty. Nor does the author's technical contribution to the purification of the cortical hormone justify his condescending attitude towards earlier investigators. A relatively short and selected bibliography completes the book, which is too technical to appeal to the practising physician.

M. A. GOLDZIEHER

A Yankee Saint. John Humphrey Noyes and the Oneida Community. By Robert A. Parker. Octavo of 322 pages, illustrated. New York, G. P. Putnam's Sons. 1935 Cloth, \$3 75

This book is a biographical description of John Henry Noyes and his Oneida Community, a remarkable company of humans which created a sensation in the middle of the last century, owing to their peculiar manners and customs, which were at wide variance with the generally accepted ideas of society at large. In it, as one critic remarks, "the reader is presented with a full-length portrait of an indomitable Don Quixote of the spirit, and a whole gallery of eccentric and fascinating characters." His was a regime of christian communism, which extended to the most intimate relations of life, including "complex marriage," based on "male continence."

He claimed to have made a scientific contribution to the technique of birth control, and an attempt was made to inaugurate a system of procreation, or "stirpiculture" in the Community. His eugenic theories are said to agree remarkably with those of today. Havelock Ellis is quoted as regarding Noyes "a very great figure, one of the noblest pioneers America has produced." Bernard Shaw and H. G. Wells also pay tribute to the extraordinary independence and logical persistence of Noyes and his Community in adhering to the tenets of his cult, not only in expression, but action.

The book is well written and historically interesting, not only as a record of a peculiar sect, but also of the reaction of the public at large, and the church in particular, to the activities and practices of a community in which sex-life was a dominating feature. The book offers little for the general practitioner, but it should interest psychiatrists and those specially interested in eugenics. In many ways it reads like a novel with a historic background.

J. M. VAN COTT

One chapter of the book is devoted to natural cures. Most of the cases cited however are those of gall stones.

For the undergraduate this volume can be used as a supplement in teaching the basic elements of surgery.

HERBERT T WIKLE

Examination of the Patient and Symptomatic Diagnosis By John Watts Murray, M D Second edition Octavo of 1219 pages, illustrated St. Louis, The C V Mosby Company 1936 Cloth, \$10 00

The second edition of this very helpful work has increased its value to the general practitioner by placing a greater emphasis upon "the common ailments which may endanger life and always are a serious source of worry and annoyance to the patient." The author very properly stresses the importance of a thorough history as a "necessary prelude to a first class diagnosis." And yet in the outline of the "Schedule for Preliminary General Examination" there are approximately two hundred thirty-eight items to be noted. One doubts its practicability without reflecting on its usefulness.

This is a book that should be close at hand at all times and the more frequently the younger practitioner consults its pages, the firmer will be his foundation for correct diagnosis.

S R BLATTEIS

Atlas of Human Anatomy By Jesse F Williams, M D Octavo of 64 pages, illustrated New York, Barnes & Noble, Inc 1935 Cloth, \$2 00

Thirty-two pages written in clear, non-technical language for the layman, cover the minimum essentials of anatomy and physiology of the human body.

There are 27 pages of illustrations in eight colors and labelled both in English and in the Basle Anatomical Nomenclature. These charts are the first of their kind done in this country and are real works of art. They are clear, accurate and well labelled.

DAVID KERSHNER

Röntgenology the Borderlands of the Normal and Early Pathological in the Skiagram. By Alban Kohler, M D Second edition. Quarto of 681 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$14 00

The first English edition of this book was in recent years the only complete discussion of the normal and early pathological findings in Röntgenography in American literature. This book is almost encyclopedic in character and is the outstanding study and reference book of its type. The present second revised English edition has been

brought up to date (to the Summer of 1935) by a complete review of the German, British and American literature. The additions are too numerous to be detailed here. While there is no discussion of the special contrast and other recent techniques of Röntgenography, this book should really be obtained as one of the bases of a Röntgenological library. It is undoubtedly one of the best X-ray books that the reviewer has ever read.

E. MENDELSON

Surgical Emergencies in Children. By Harold C. Edwards, M S Octavo of 274 pages, illustrated Baltimore. William Wood & Company 1936 Cloth, \$4 50

Printed in clear type and quite readable this small volume should be a welcome addition to the library of the surgeon.

The section devoted to the gastro-intestinal tract is quite complete and the treatment outlined conforms with the accepted procedure.

Our local "flu-belly" peritonitis is recognized as influenzal peritonitis and the danger signals set against too early operation. We stress, however, the ever present danger of confusing flu-belly with acute appendicitis. For anesthesia in emergent operations in children the author favors gas-oxygen in preference to the safer and equally efficient open drop ether. While sketchy in places the book fully meets the requirements of its title.

STANLEY B THOMAS

Pediatric Nursing By John Zahorsky, M D Assisted by Beryl E. Hamilton, R N Octavo of 568 pages, illustrated St. Louis, The C V Mosby Company 1936 Cloth, \$3 00

This is a book of 568 pages with 144 illustrations and 7 colored plates. These facts alone place it in a class by itself and before reading, one wonders whether the essentials of pediatric nursing could not be given in less space. After reading, however, one appreciates that the questions at the end of each chapter are a valuable part of the book, and add to its extent. The glossary and index help to do the same.

It is a good text-book for undergraduate nurses and will give a postgraduate course in pediatric nursing to the one who wants to keep up to the minute in infant and children's nursing.

It is refreshing after the recently attempted theoretical confusion in classification of tuberculosis to find the author makes the practical clinical classification of 1 Infantile type 2 Juvenile type 3 Adult type. 4 Extrapulmonary tuberculosis.

Histology By S Ramón-Cajal, M D Revised by J F Tello-Munoz, M D, authorized translation from the tenth Spanish edition by M Fernan-Nunez, M D Octavo of 738 pages, illustrated Baltimore, William Wood & Company, 1933 Cloth, \$8 00

Ramon-Cajal's text-book of Histology is of interest as a pedagogical effort of one who has international recognition as an investigator in this subject His ripe scholarship is evident in many of its parts

The book has a mature viewpoint with many references to the leading investigators in various fields, and to a variety of techniques It is a question to be decided separately for each school whether it is best to present so much material to the medical student, or whether a somewhat more elementary and shorter exposition of the subject would be more suitable.

There is an introductory section of over a hundred pages that has the value of stressing the plasticity and activity of the living cell It seems that the order of this section might have been improved by some such sequence as,—cell structure, cell chemistry, the living in contrast to the dead cell and cell relations Some of the discussion of new human material in this section seems not necessary for most American medical students as they will have met its equivalent in their previous biological courses

In the sections on muscle, connective tissue and the nervous system, the author's thorough acquaintance with the results of metal impregnation and related methods is clearly shown It would have been well had there been in these sections, a clearer distinction made between structures which have been seen in the living cell and those which have only come to light by the use of techniques which may have profoundly changed the organization of the dead remnants of cells to which they were applied

The book has many useful illustrations

EDGAR D CONGDON

The Early Diagnosis of Malignant Disease. For the Use of General Practitioners By Malcolm Donaldson, F.R.C.S., Stanford Cade, F.R.C.S., William D Harmer, F.R.C.S., R. Ogier Ward, F.R.C.S., and Arthur T Edwards, M D Octavo of 168 pages New York, Oxford University Press 1936 Cloth, \$3 00

Several authorities have collaborated in the writing of this brief work. The intent is to provide the general practitioner with such facts as will enable him to more readily recognize or suspect malignant disease in an earlier stage.

Choice phraseology leave imprints never to be forgotten "Early diagnosis of mammary carcinoma should be made with the mind's eye first, the microscope next, and with the hands, eyes and nose, if ever, last", "Differential diagnosis of early carcinoma does not depend on the absence of

signs of advanced carcinoma, but in the similarity between early carcinoma and benign lesion"

Aphorisms are generously distributed throughout the text "The necessity of early thorough investigation of any bleeding from the genito-urinary tract", "The importance of diagnostic curetage in every patient suffering from post-menopausal bleeding", "The importance of suspecting carcinoma of the larynx in men past 40 with persistent hoarseness", "The commonest early sign of carcinoma of the rectum is irregularity of the bowel", "No case of rectal bleeding should be labelled piles without a thorough investigation"

The book deserves a wide circulation

HARRY MANDELBAUM

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc. Volume 1, 46th Series, 1936 Edited by Louis Hamman, M D Octavo of 314 pages, illustrated. Philadelphia, J B Lippincott Company 1935 Cloth, \$3 00

This volume includes articles of interest in medicine and surgery Simmonds disease is reported in a patient observed over a period of twelve years with careful study Fever in heart disease, of infectious and non-infectious origin is presented. Soma Weiss has given a careful review of the uses and dangers of various sedatives and hypnotics Basal pulmonary tuberculosis and pulmonary embolism are well presented A complete review of portal hypertension is given There is a review of the progress of surgery in 1935 This issue of the Clinics upholds the high standard and value of this publication. HENRY M MOSES

Cardiac Output and Arterial Hypertension. By Sidney A. Gladstone, M D Octavo of 56 pages, illustrated New York, Sidney A Gladstone, 1935 Cloth, \$1 00

This little volume of 56 pages is an attempt on the part of the author to clarify the relationship of arterial hypertension to kidney disease He combines the views of various observers into a simple and logical hypothesis Arterial hypertension results from an adaptation of the circulation to a pressure level sufficient to meet the needs of glomerular filtration. The heightened pressure level is due to a pressor substance which enters the blood in increased amounts when there is obstruction to the urinary flow The pressor substance is formed in the cells of the proximal convoluted tubules and enters the blood through the thin-walled portion of the loops of Henle. The pressor substance is a chemical substance which is synergistic with adrenalin The author does not name guanidin as the offending chemical substance. SIMON FRUCHT

Skippy and David Explore THE *New* BOOK OF KNOWLEDGE

"WE ARE a second generation Book of Knowledge family," writes Mrs E M Rutter, mother of the boys pictured above. "I was brought up on, and adored, the first edition that came out more than twenty five years ago. As soon as I saw your wonderful new edition, I felt that it was absolutely necessary for the boys to have it for their school work and for home reading. I notice how wonderfully you have kept up with all the changes. I don't want to praise my own children, but it certainly has put them along in school and it is the best possible background a child can be given."

Already in the Homes of
3,500,000 Children

The Book of Knowledge introduces the boy and girl to the world of knowledge in the happiest and most interesting way. By means of his own natural curiosity the child is led into the wide fields of Nature Study, Science, History, Biography, Literature, etc. 15,000 striking pictures provide visual edu-

cation in its simplest and finest form. The Book of Knowledge, already in the homes of 3,500,000 children, stores the mind with useful information and exerts profound influence on character.

The Trained Mind Wins

When your child starts asking "Why is the sky blue?" "Why are raindrops round?" and the hundred other daily questions that bespeak an eager, inquiring mind, that is the moment, THE MOMENT OF INTEREST, when The Book of Knowledge should be at hand, to supply the right answers. The child whose questions are answered becomes a well informed man or woman, with a clear, trained mind, prepared for success. In school days and in the fierce competition of grown up years, the trained mind carries off the biggest prizes. The Beautiful Free Booklet will delight your boy or girl. Send for it today.

SMOKING AGAINST DOCTORS' ORDERS!

IT is easy to tell a patient to stop smoking, but it is often difficult to make him follow the advice.

We do not advocate smoking against doctors' orders, but we do say that if your patient insists on smoking, he should smoke a cigarette proved* less irritating

Philip Morris, due to the use of diethylene glycol, are less irritating than ordinary cigarettes in which glycerine is used as the hygroscopic agent.

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines its step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will.

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

STRICTLY
HIGH
CLASS
PRIVATE
SANITARIUM

recognized for 50
years by the medical
profession

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases.

Environment and administration are such as affords the most beneficial atmosphere. Contact with others is controlled through caring for the patients in suites (practically all with private baths). A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanatoria.

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal. The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere.

Travel and Resorts

There's Something About Bermuda—

The Bermuda Trade Development Board cordially invites the inquiries of prospective visitors who may desire information. The office of The Visitors' Service Bureau is situated in Hamilton at the corner of Front and Queen Streets, adjoining the Ferry Terminal. A representative of the Bureau meets all incoming ships, and the members of its staff are at all times ready to serve visitors in every possible way. Suggestions are available for attractive drives, and railway and water trips, what to see and what to do, and the points of interest—too numerous for mention here—which should not be missed.

The Bermudas are named after Juan de Bermudez, who discovered them prior to 1511. In 1609, Admiral Sir George Somers and a party of Virginia colonists were wrecked near the site of St. George, eventually continuing their voyage to Jamestown. After Somers returned to Bermuda and died there, the islands were colonized, in 1612, by the Virginia Company, succeeded by the Bermuda Company. In the Somers Gardens at St. George are two memorials to the Admiral. Bermuda is the oldest self-governing colony in the British Empire, and its Parliament the oldest law-making body, excepting only the Mother Parliament in London. The Bermuda Parliament consists of the Governor and Commander-in-Chief, always an officer of the British army, nine members of the Legislative Council, appointed by the Crown, and thirty-six members of the House of Assembly, elected by vote, four from each of the nine parishes. Of the 30,000 inhabitants (estimated, 1933) about one-half are white, mostly of English stock and tracing their ancestry to the earliest settlers.

Bermuda's mild winter climate, scenic charm, and restful environment, are enjoyed annually by an increasing number of visitors who spend the season in the Colony. Furnished and unfurnished cottages may be rented for the winter or summer season, in various parts of the Islands, and the cost of living is reasonable. Excellent private schools are available for children of all ages.

Visitors should bring to Bermuda an outfit similar to that used during a summer sojourn at a northern resort. In summer, a light overcoat or raincoat for use on shipboard is necessary, while in winter heavy clothing usually will be needed when leaving and returning to

northern climes. Ladies should have warm wraps to wear over their light gowns in the evening. In summer ladies will find that wash silks, voiles, muslins, and other washable light clothing worn in Canada and the United States, will meet all requirements while in Bermuda.

Bermuda's location as the hub of steamship lines from Europe and other parts of the world, makes it a cosmopolitan market-place of the most desirable products, particularly

including men's and women's wearing apparel from England and France. The latest foreign fashions reach Bermuda frequently in advance of their showing elsewhere, and excellent values may be obtained by taking advantage of personal customs exemptions.

Agriculture in Bermuda consists of the production of vegetables, milk, eggs and other produce for local consumption, and of winter-grown vegetables for export to Canada. Lily bulbs and buds and early potatoes are shipped to New York. About 1,800,000 quarts of milk are produced annually for local consumption. All dairies are subject to frequent inspection by the Government, and dairy cattle are annually tested for the presence of bovine tuberculosis, from which all herds are remarkably free. Delicious strawberries are grown during the winter months, and Bermuda bananas are the delicate Chinese or Canary variety. Increasing quantities of vegetables and other farm produce are sold locally, to the estimated value of £168,000 in 1933. In the same year the farm values of exports to Canada and the United States were £24,800 and £10,400 respectively. The principal vegetables exported to Canada are onions, cabbage, celery, potatoes and tomatoes (in order of quantity). The quantities of export vegetables centrally graded and packed by the Department of Agriculture, in the last four years were respectively 1,333, 13,968, 54,613 and 93,332 crates annually. Government packed vegetables are sold under the "Colonial Mark," a pink oleander.

Bermuda offers rare enticements for the angler. Four hundred and sixteen species of fish abound in the islands, including such popular game fish as Amber-Jack, Barracuda, Bonita, Bermuda Chub, Crevelly, Dolphin, Grouper, Horse Mackerel, Marlin, Rock-Fish, Snappers, Tuna, Yellow-Tail and Wahoo. The Bermuda Chub, which often weighs 16 pounds or more is,

Dr. Ely Joins Stearns Staff

Frederick Stearns & Company announce the appointment of Lloyd L. Ely, M D as medical director

The addition of Dr Ely to the scientific staff of this well known pharmaceutical house is a definite step in the research and professional expansion which Mr Frederick S Stearns has been fostering for the past several years

Dr Ely is a graduate of the State University of Iowa, and after his internship acquired some valuable clinical experience with Dr Frank Smithies, famous Chicago internist and gastroenterologist.

In addition to his private practice in Chicago, Dr Ely also held teaching appointments at the medical schools of Illinois and Loyola.

Always interested in diabetes and in the development of useful therapeutic agents, Dr Ely in 1926

joined the Lilly medical staff, where in 1934 he became director of the Department of Medical Therapeutics. His acute interest in diabetes and the recent advances by Frederick Stearns & Company in the development of more promising forms of insulin led him to join the staff of the latter organizations

Dr Ely has a wide acquaintance with clinical investigators and his association with Frederick Stearns & Company is especially significant at this time, because of the intense research activities being carried on in the Stearns Scientific Laboratories

Dr Ely has been a member of the Chicago and Indianapolis Medical Societies, the Illinois and Indiana State Medical Associations, the American Medical Association and the Society for the Study of Internal Secretions—ADV

Atlantic City's Winter

Known at one time as a summer playground only, Atlantic City has for years been recognized as an all-year-'round health and pleasure resort.

The great seashore metropolis in the summer and the winter differs only so far as sports are concerned. Swimming, beach games, sun bathing, fishing and sailing are the most popular in the summer months while with the change of seasons thoughts turn to golf, bicycling, horseback riding and hunting.

Of course there are also the salt water swimming pools in the hotels, ice hockey on the rink in the municipal convention hall with games between the Atlantic City Sea Gulls and leading amateur teams from this country and Canada, basketball with the Sand Snipers playing host to the nation's best professional clubs and the annual squash tournaments attracting the cream of the racquet wielders.

All of these have proven popular with the visitors and each season sees increased numbers attending the various sports attractions on the winter schedule. Atlantic City's mild climate the year 'round makes the winter vacation more enjoyable and the resort is famous for its boast of "no snow on the Boardwalk."

With the varied demands from the millions of visitors, the city has reached the point where practically any and every type of activity desired can be obtained. Boardwalk rolling chairs, benches along the ocean rail, comfortable sun decks on the piers and hotels, and the canvas backed beach chairs are here for those seeking rest and relaxation.

Huge airplanes are waiting at the Municipal Airport and at the Inlet hangars to take up passengers for either a short sight-seeing trip or a hurried jump to some distant city. The modern facilities at the airport, the first municipal one to be opened in the United States, have proven attractive to aviation enthusiasts and each season finds an increased number of vacationists arriving here by air.

Five splendid golf courses are within easy reaching distances. The Northfield and Linwood Country Clubs, and the Brigantine, Ocean City and Seaview Golf clubs, being just a few minutes' automobile ride from the heart of the resort. The Boardwalk bicycle lane, open from 6 a. m. to 9 a. m. daily, has proven popular and the stands where cycles may be rented are frequently hard pressed to meet the demand.

The wide, level, eight-mile long stretch of beach has become a popular bridle path for the equestrians. Here horseback riding may be enjoyed from October 1 to June 1. Saddle horses, as well as ponies for the children, may be obtained at several stands along the beach.

Pleasure-planned WINTER CRUISES

FURNESS ships . . . Furness service . . .
Furness meals . . . Furness entertainment . . .
and Furness ports! Add them all together, and you'll find they make the biggest sum-total of vacation pleasures that you can find combined in one ocean cruise! The Monarch of Bermuda and Queen of Bermuda are the acknowledged leaders among pleasure vessels . . . because of their unique "pleasure plan" including great sweeping Sports Decks, swimming pools, cocktail bars, dance decks, theatre and sumptuous lounges. Unique, too, are the living quarters of these magnificent twins—each room has its own private bath.

"Where Furness goes, I will go," say many travelers. It's a good rule to follow!

TO BERMUDA . . . Frequent sailings on the Monarch of Bermuda and Queen of Bermuda from New York direct to the dock at Hamilton. Round trip \$50 up (\$60 up off Dec. 19) including private bath. Also low all-expense trips of varying duration including private bath aboard ship and accommodations at a leading Bermuda hotel.

TO BERMUDA and NASSAU . . . Ask about special Triangle Cruises on the Queen of Bermuda 7 days, \$75 up, including a daylight day in Bermuda and 11 A.M. to midnight in Nassau. Special entertainment under expert Cruise Directors.

TO THE WEST INDIES . . . Frequent cruises throughout the Winter season to 15 enchanting ports of the Little West Indies: the Windward and Leeward groups aboard the popular steamers Fort Townsend and Nerissa.

week, which visitors may join

Bermuda possesses natural advantages for
golf which probably are unsurpassed if not un-
equaled All of the seven courses have true
"northern" turf, Bermuda is the home of the
famous "Bermuda grass," which provides an
ideal playing surface for golf greens and fair-
ways Four of the courses are of 18 holes The
ideal year-'round climate ensures constantly en-
joyable playing conditions The rolling terrain,
liberally interspersed with water areas, and the
wealth of charming views, have inspired golf
architects to make the most of the exceptional
opportunities Five of the seven courses are
open to visiting players throughout the year,
upon payment of moderate greens fees Golfers
of either sex are cordially welcomed in Ber-
muda and will enjoy competing in the frequent
tournaments, suitable for all classes of players

Announcing Florida Winter Service

America's famous winter train "The Florida
Special" of the Atlantic Coast Line will cele-
brate its 50th year of service with its inaugura-
tion on Saturday, January 2nd, leaving New
York at 1 15 P M This train, operating as
many as 6 and 7 sections in seasons past, has
made a remarkable record for fast safe travel
and is expected to break all its existing records
for passengers carried this season

Public acceptance of the Recreation Car,
with hostess, orchestra and all of its features,
ensures the inclusion of this service for the
Aristocrat of Winter Trains

The Coast Line's well-known Miamian and
Gulf Coast Limited will begin their Florida
service—The Miamian serving the East Coast
of Florida, the Gulf Coast Limited serving
Central and West Coast points—on Dec. 10th
with new improved schedules

The Havana Special, with its famous lounge
car, will also provide service from Boston and
New York to both Florida Coasts, furnishing
connections by steamer and plane for Havana
and beyond

The Palmetto Limited continues its service
between New York, Washington and Wilming-
ton, N C, Charleston, S C, Augusta and

by Babe Ruth or any other ball player would not carry from one end to the other

A striking feature of the place is its versatility for ice hockey and skating, a sheet of ice, 100 by 200 feet is frozen on the floor. The ice can be disposed of in a few hours' time and the only full sized indoor football field in the world laid in its place. Or the 140,000 square feet of floor space may be set up with hundreds of exhibit booths, each independently equipped for gas, water, sewerage, electricity, steam and compressed air. Also at the end of the vast auditorium is one of the largest and best equipped stages capable of seating 5,000 persons

The adaptability of the building and its facilities is better understood when it is considered that practically every type of convention and exposition has been staged here, as well as track meets, prize fights, dog racing, ice hockey, horse shows, horse racing, polo, football, and varied other events too numerous to mention.

And no visit to the hall would be complete without stopping a few minutes to listen to the famous organ, by far the largest and most powerful ever built. It is equipped with two giant consoles, one with seven manuals and the other a movable one, with five. There are 1255 speaking stops and 33,000 pipes ranging from 3/16ths of an inch to 64 feet in length. It is run by a 365 h p group of motors, has seven blowers and its own generator. The wiring used would girdle the earth twice. Four years' time was necessary to complete this organ at a cost of \$500,000.

The convention hall also houses municipal radio station WPG, known the world over as the "Voice of Atlantic City" and visitors are welcome to inspect its many facilities at any time

Britain to War on Winter Fog

"If every soldier in the Rebel armies now attacking Madrid—about 100,000 strong—should fire 12-1/2 rounds of ammunition, one would have approximately the noise of the 1,250,000 detonators to be used this season by one railroad alone, the London, Midland and Scottish, in Britain's war on winter. But the British bombardment is for the preservation of lives and property and against the railroad man's deadliest enemy—fog," declares T R Dester of the Associated British Railways

"Like the ammunition of an advancing army, large stocks of detonators have been accumulated at strategic points along the line, while special "shock troops," seasoned employees recruited from the permanent way department, stand ready at all times to rush to

Duck and quail hunting are very good in this vicinity and with the close of the fishing season in mid-fall many of the fishermen turn to the guns to provide the season in sport.

The great amusement piers, that in some cases extend almost a half-mile out over the ocean, will never be forgotten by anyone who has ever visited Atlantic City. Perhaps one of the most famous of its kind is the Steel Pier where the greatest variety of attractions ever assembled under one roof can be witnessed for a nominal admission in the summer months. It is impossible to take in all the pier's features in one visit, even if an entire day is spent on the structure. Winter finds a number of the attractions continued. Fishing, deep sea aquariums, and net hauls continue well into the winter at Young's Million Dollar Pier. National exhibits on Steel, Million Dollar, Garden, Central and Heinz Piers remain open throughout the winter.

Four Boardwalk motion picture palaces provide the visitor with early showings of current films. Restaurants, hotel grilles, supper clubs and cafes all feature well known dance orchestras and entertainers at remarkable reasonable prices.

The Boardwalk hotels, long famous as some of the finest in the world, now provide rates, lower than in years and well within the means of everyone. These skyscrapers along the beachfront are ready to cater to every wish of their thousands of guests. The Boardwalk also offers miles of smart shops, where high class merchandise from all corners of the globe is on display.

At the lower end of Absecon Island, on which Atlantic City is situated, are the exclusive residential suburbs of Ventnor, Margate and Longport, where fine homes of every description can be seen. These suburbs, along with the Chelsea section of Atlantic City, are popular with those visitors, who rent cottages for their visits or once here decide to make this their home.

Any visitor to Atlantic City will not leave here without first spending a few hours inspecting the huge municipal convention hall, by far the largest in the World. Built on the Boardwalk, between Georgia and Mississippi avenues, at the cost of \$15,000,000, the structure covers seven acres of ground and seats 40,000 persons in the main hall, while the entire population of Atlantic City—66,000—can be seated in the building with room to spare.

New York City's famous Madison Square Garden could be placed in one corner of the main hall and a track meet and several large gatherings be staged concurrently in the remaining area. The longest home run ever hit

TODAY'S CENTER

THE WALDORF-ASTORIA

PARK AVENUE 49TH TO 50TH NEW YORK

Van Hoevenberg, famous as the site of the Olympic bobsled run

Early this month the State Conservation Department began work on the Marcy run. The local CCC camp will supply labor for the project. Following generally the old foot trail, the new development will take the ski-runners down a total descent of 3,189 feet, a distance of six and one-half miles to Adirondack Lodge, passing such well-known landmarks as Plateau camp, Indian Falls, and Marcy dam. Only 94 trees will be cut to make the trail suitable for skiing, Conservation Department officials say.

Every skier, from novice to expert, will here find something to his liking with the added attraction of the gorgeous view from the summit of Mt. Marcy, called by the Indians "Tahawus, the Cloud Cleaver." The first 544 feet of the run are above the timber line.

Winter's snows linger long on the mighty slopes of Marcy, so that devotees of the long boards can enjoy what to them is the greatest sport in the world well into the spring, even when flowers have started to peep through the moss in the lower valleys.

Recently work was started on the new Mt. Van Hoevenberg downhill run, which winds along the northeastern slope of the mountain following closely in its turns the Olympic bob-run adjoining it on the west. It is nearly a

Baltimore offers no finer address than The Belvedere. Recently modernized throughout, its uptown location and excellent facilities appeal to those who value comfort and gracious living. Most convenient to the city's leading hospitals and medical centers. Rates begin at \$4.00.

John R. Folger,
Manager

The Belvedere

CHARLES STREET AT CHASE
BALTIMORE

the danger points, at the first appearance of fog, snow or ice.

"Another striking military parallel, the snow plough, which may be compared with the tank, is relied upon in Britain's war against winter's forces. During spells of severe weather, regular snow plough patrols are maintained by the London, Midland and Scottish Railway over such exposed and mountainous sections of the line as those between Hellfield and Carlisle, and between Perth and Inverness, the latter run including the snow-infested County March, and the Drumochter and Slochd Summits which are respectively 1,484 and 1,315 feet high. Tons of anti-freezing salt are used on all heavy weather runs.

"Thus, the railways mobilize men, explosives and machinery—the destructive forces of war—for the protection of human lives and property."

Winter at Lake Placid

Soon they'll be skiing down from the clouds at this resort.

Two new downhill ski runs are now in process of construction—one from the peak of Mt. Marcy, the highest mountain in New York state, 5,344 feet above the level of the sea, down to Adirondack Lodge, and the other on Mt.

Sea air is good for convalescents

Doctors say that sea air, rest and good food build back health. Tiresome journeys are avoided by recommending the Half Moon, New York City's only ocean front hotel, a short half hour from Borough Hall, Brooklyn. Luxurious, modern accommodations at moderate rates are supplemented by these important features:

SPACIOUS SUN DECKS ON OCEAN
SALT WATER BATHS
SPECIAL ATTENTION TO DIET

excellent downhill runs at Lake Placid and will make up a part of the 250 miles of ski trails which radiate from this resort in all directions

Royal Winter Fair to Draw Late Fall Motor Tourists

Highlighting the social and amusement calendar of Dominion activities, particularly in the capital of Ontario, next month, will be the annual Royal Winter Fair and Horse Show, November 18 to 26, inclusive

The particularly mild climate of Toronto along the lake front makes it a magnet for motor tourists during the latter half of November, thousands of whom are taking their regular, or an extra vacation during the mild, yet crisply-clear Autumnal season. The Royal Horse Show, this year, immediately follows the National in New York City and is always the first event of its kind during the fall and winter in Canada.

Situated equi-distant from New York and Chicago, and being the second largest city in Canada and the largest in the province, Toronto is fortunately located for the fair and show, which ranks second only to the Canadian national exposition. The affair is both national

and international—national as representing Canada from ocean to ocean, and international in its inclusion of leading American stables with exhibitors and horses from six different countries.

Motor car owners comprise virtually the entire group, thousands nightly, to witness the horse show. There is a tang of unusual freshness about it—its smart assemblage of Canadian society, headed by his Majesty's representative, its sprinkling of old-world leaders, its hearty, American friendliness, its strikingly fine entries, the military smartness of its ring work, and its high class panel of judges for the occasion.

The locale of the Royal Winter Fair and Horse Show is within a few minutes motor drive of the Royal York Hotel, largest hostelry in the British Empire, and of the railroad stations. Garage accommodations and parking spaces are available within the immediate vicinity of the Royal York. Around the Horse Show proper, adding to its inherent sparkle and brilliance, is to be found a vast assemblage of animals and birds in "Ten Big Shows in One," as it is billed.

Visitors motoring to Toronto will have ample opportunity to see Niagara Falls from both the Canadian and American side, in a setting of evergreens and red and gold fall leaves,

FERNDAL, NEW YORK

mile from the start of the run at the top of the mountain to the finish at the bob clubhouse

The course will be approximately 15 feet wide on the straightaways, widening out to 70 feet maximum on some of the great curves. Classed as an intermediate or expert run, the new trail will contain several 20 per cent grades, plenty of thrilling action for the most experienced skier.

Here it will be all "slide," as Conservation Department trucks will take the skiers to the top of the mountain at a nominal charge.

One-third of the run is on state land and two-thirds on property donated to the North Elba park district by the Lake Placid club. Cost of construction will be about \$1,000. The new run will be ready for use late in November.

For racing, a Lobner electric timing device will be installed, which will record times of contestants in hundredths of a second.

Experts say that the new development on Mt. Van Hoevenberg will be one of the finest downhill ski runs in the northeastern United States. It will take its place with the five other

The doctor looks at Santa Claus

WHAT'S THIS? Our old friend Santa in trouble?

Not exactly. He's just as bouncy and jolly as ever. His smile would light up a coal mine. But he is getting just a wee bit worried about his waistline. And well he might.

For obesity is dangerous. Superfluous weight makes every movement a greater tax on strength than that movement would be if weight were normal. It places an added burden on the fat person, a burden he carries wherever he goes whenever he moves. And most of all, it places a serious and unfair strain on the heart by making it do extra work. It has been estimated that putting on twenty pounds of fat adds about twelve miles of blood vessels and capillaries through which blood must be pumped. And the heart,

of course, must do the pumping.

You've often heard people say, "I must go on a diet" or "I must go in for some strenuous exercise and work this fat off." But either course may be dangerous. Unwise dieting frequently substitutes, for the evil of obesity, the evil of undernourishment. Strenuous exercise obviously adds to the burden on an already overburdened heart.

There is only one sane thing for any overweight person to do. That is to see his doctor. Your doctor can determine whether obesity is caused by some fundamental physical disorder—such as glandular derangements—or whether it is the result of unwise eating combined with insufficient exercise.

Diet is a form of treatment, and it

should *never* be prescribed by anyone but a physician. The doctor's knowledge is necessary in determining what foods, and how much, may be eaten—what diet will be safe and pleasant, yet effective, in removing unneeded, unsightly fat.

If you are overweight, or in doubt about what weight you should maintain, do something about it. But don't let well-meaning friends, or the fellow you met while on vacation, prescribe for you. See your doctor.

WEATHER FORECAST— HEAVY SMOKEFALL

SMOKE exerts a definite influence on the weather at this season by reducing the amount of sunlight. Beginning in September there is a steady rise in atmospheric pollution until in December it becomes double that of midsummer, according to a recent report of a two-year study made by the U S Public Health Service in ten of the largest American cities, representing a population of millions. One of the most surprising findings was that there is no decrease in the dust content of the air either during or after a rain.

Average atmospheric pollution in 10 large American cities, 1931-1933
It is probable that conditions are similar in many smaller cities especially where soft coal is used and wind velocity is low

Winter Sunlight an Unreliable Antiricketic

Atmospheric pollution is but one of many forces militating against the therapeutic effects of ultraviolet rays in winter. Others, to name only a few, are cloudiness, precipitation, and clothing. In winter, moreover, it is often impracticable to give sunbaths to infants during the very time they are most susceptible to rickets—the first six months of life.

Dependable the Year 'Round OLEUM PERCOMORPHUM

Price Substantially Reduced, Sept. 1, 1936!

The physician can dispel uncertainty in the treatment of rickets simply by prescribing a few drops of Oleum Percomorphum daily. The product has the advantage of having the same ratio of vitamins A to D as in cod liver oil,* with 100 times the potency. Each gram supplies not less than 60,000 vitamin A units and 8,500 D units (U S P). This maximum vitamin potency in minimum bulk gives Oleum Percomorphum outstanding usefulness for young and premature infants. Constant bioassay and special processing of this antiricketic assure the stated vitamin potency and low percentage of fatty acids. Supplied in 10 and 50 c.c. bottles and 10-drop capsules in boxes of 25 and 100.

*U S P minimum standard.

Manufacturers of Vitamesol

Proctologists

THE YEOMANS' PROCTOSCOPE is an ideal examining and operating instrument, providing direct illumination, light rays focused at the distal end. The light carrier fits accurately into the auxiliary tube with only the lens projecting into the main tube. The vision of the observer and the path for the introduction of instruments for examination, local applications or operation is always clear, there being no obstruction in the tube.

The entire instrument may be carried in the physician's bag and for this reason is supplied without a case. All parts of the instrument which come in contact with the patient may be sterilized by boiling. The Yeomans' Proctoscope complete with 10" x 1/8" tube, obturator, light carrier, conducting cord, lens cap, lamp and inflation bulb sells for **\$33 50**

Other size tubes are available in this set including, infant and sigmoidoscope.

A doctor asks—

TARSSO SUPINATOR the orthopedically correct shoe designed for use by the physician in his treatment of flat feet in children.

The Tarsso Supinator shoe adducts the tarsus by a supinating action from the Calcaneo Cuboid joint back bringing the tarsus into a varus position and the bones of the arch into correct alignment.

The correction is built into the back of the shoe wherein lies the deformity. Tarsso Supinator thus brings the arch into Normal alignment and Correct Posture.

INVESTIGATE the Tarsso Supinator principle more intimately—send for description folder

Are you cold to facts?

The common conception of Alaska is a cold, bleak, dreary country, once the scene of a dramatic gold rush. A frigid, white elephant to some

Its milder zones and enormous undeveloped resources are so unknown that for a long time a single company had no competition. Few realize that Alaska pays a yearly return of more than its total purchase price. More than twice the amount paid for this territory was returned in gold alone over a period of ten months. Products from her soil and waters brings the value of its yearly production to eleven times the price paid Russia for this possession.

In this JOURNAL there is an Alaska, not cold and forbidding, but one also full of undeveloped resources. A gold mine of opportunities in advertisements that can bring year-after-year dividends—profitable returns many times the value of an investment of a few minutes of reading time.

If advertisers find YOUR JOURNAL an excellent territory for developing their business, there should be more reason for you, yourself, to make the JOURNAL an asset to your practice.

Just a year ago Lederle introduced—

LOBULIN *Lederle* MODIFIED

ANTITOXINS

IT HAS BEEN A YEAR of appraisement and ever-increasing usage. The Globulin-Modified *Lederle* technique, embodying the principle of peptic digestion, is the only practical procedure which permits such a high degree of concentration of antitoxin and reduction in the amount of troublesome proteins—the cause of serum reactions.

That is why Globulin Modified Antitoxins *Lederle* represent

- a reduction in the expected incidence and severity of serum disease,
- less inconvenience to the patient,
- a greater ease of administration,
- a greater potency per cc.

At one of the outstanding hospitals 250 patients treated with a Globulin Modified Antitoxin showed a serum disease rate of less than 5%—all indicating a delayed type of serum reaction.

VITAMIN UNITS AND STANDARDS

● The past five years have brought agreement between biochemists of the various nations as to suitable units and standards of reference for most of the vitamins essential to man. The practice of expressing the vitamin potencies of foods and other biological materials in terms of *International Units* is, therefore, fast becoming universal.

Believing that these units and the standards upon which they are based would be of interest to our readers, they have been tabulated and defined below (1)

Vitamin A

The reference standard is a solution of pure beta carotene in an inert oil, of such concentration that one gram of solution contains 300 micrograms (0.300 mg.) of beta carotene. The International Unit, or *IU*, of vitamin A is the vitamin A activity of 2 mg. of this standard solution, or 0.6 micrograms of beta-carotene.

Vitamin B₁

The reference standard is the concentrate produced from rice polishings, by a specified adsorption method, in the Medical Laboratory of Batavia (Java). The International Unit for vitamin B₁ is the vitamin B₁ activity of 10 mg. of this standard adsorption product.

Vitamin C

The standard of reference for vitamin C is a specified sample of pure levo-cevitic acid (levo ascorbic acid). The International Unit for vitamin C is the vitamin C activity of 0.05 mg. of this standard.

Vitamin D

The reference standard for vitamin D is a solution of irradiated ergosterol, prepared under specified conditions at the National Institute for Medical Research (London). The International Unit for vitamin D is the vitamin D activity of 10 mg. of this standard solution.

These International Units for expressing vitamin contents have been specified in the most recent Pharmacopoeia of the United States (2) as well as by the Council on Pharmacy and Chemistry (3) and the Council on Foods of the American Medical Association (3), and provision has been made for distribution of the standards in this country (4).

These units have been used to express vitamin potencies in recent studies on canned foods, the results of which further emphasize the fact that these foods rank among the most important sources of the vitamins essential in human nutrition (5), (6), (7).

Tell your
patients, Doctor . . .

that
*Ralston cooks
in 5 minutes*

Because so many mothers insist on using easy-to-prepare cereals, it's important that you remind them that Ralston cooks in 5 minutes. And of course, it's even more important to you and to your patients to know that Ralston is . . .

• A WHOLE WHEAT CEREAL . . . with only the coarsest bran removed . . . providing an abundance of the body-building, energy-producing elements that come from choice whole wheat.

• DOUBLE-RICH IN VITAMIN B . . . pure wheat germ is added to Ralston to make it $2\frac{1}{2}$ times richer in vitamin B than natural whole wheat.

• PALATABLE AND ECONOMICAL . . . tastes so good that the whole family likes it—and each generous serving costs less than one cent.

The Hot Whole
Wheat Cereal
Enriched with
Extra Vitamin B

MILK *can only* *be as pure as the* PROTECTION *it receives . . .*

MILK, as it comes from a healthy cow, is pure and wholesome. From that point on, the purity of the milk depends on the *kmd* of protection it receives. Nature intended milk to pass directly from one creature to another. She made no provision against exposure to outside elements.

That is why we, the 40,000 Dairylea farmers, provide *every* protection in the production of Dairylea Milk. On the farms, for in-

stance, we filter the milk—cool it quickly—handle it only in sterilized utensils—keep it in a sanitary building or room used for milk only. Our collecting stations inspect every can of milk. The health of every herd is certified by a competent veterinary authority. Not only at the source, but *all* the way to the consumer, Dairylea Milk is inspected and protected well beyond the regulations prescribed in health regulations — protection that should appeal to you as a doctor.

DA

Our Pledge: We, the farmers of the Dairymen's League, recognize a definite obligation to the public. Since milk is nature's most nearly perfect food, we pledge ourselves, in the production of Dairylea Milk Products, to do everything within our power to safeguard their purity and quality.

**CLINICAL EVALUATION OF A NEW TRICHOPHYTON
EXTRACT****Preliminary Report**JOSEPH JORDAN ELLER, M D and KENNETH A KAZANJIAN, M D, *New York City*

Despite the multiplicity of agents used in the treatment of dermatophytosis, local therapy has not proven satisfactory. A fungicide strong enough to destroy the organisms often defeats its purpose by producing an inflammatory reaction. As a result of the infection, the tissues may become so sensitized that the application of the weakest antiseptic ointment cannot be tolerated. Such an additional irritation may cause an exacerbation of the infection, as well as a general allergic state, manifesting itself in the appearance of dermatophytids. Furthermore, patients who once suffered from a ringworm fungus infection seem to become quite susceptible to reinfection. Inasmuch as the spores can live in hose, shoes, and on floors, there is always this problem with which to contend.

It is for these reasons that dermatologists have endeavored to attack the problem of dermatophytosis from a different angle. Their efforts turned quite naturally into a search for a biologic agent, such as a vaccine, which would not only prove effective in combating a local infection, but would also desensitize or immunize the patient. For a number of years a polyvalent trichophyton has been used with results that have been reported as more or less unsatisfactory.

Van Dyck, Kingsbury, Throne, and Myers¹ report encouraging results from the use of trichophyton vaccines. In 100 cases of fungus infections, most of them of the extremities, thirty-two per cent were cured, twenty-eight per cent improved, twenty-one per cent slightly improved, and nineteen per cent unim-

proved. Boric acid ointment was used locally. The cured cases, according to the tables in the report, showed an average period of treatment of about seven weeks.

Sulzberger and Wise² came to the conclusion that desensitization was possible, but advised the limitation of its use to obstinate and persistent cases in which the "phytids" was the most difficult phase of the clinical picture. They did not expect to cure the primary foci of infection in the feet by this method.

Traub and Tolmach³ recently reported their results in 135 cases of dermatophytosis treated with trichophyton administered *intradermally*. They state "we fail to see any rational basis for considering that intradermal injections of trichophyton are particularly useful in the treatment of this disease." Some of their patients were made definitely worse by the injections. They felt that desensitization, as manifested by failure to react to 1:1 dilutions of trichophyton, had little or no effect on the course of the disease. "There was certainly no evidence to encourage us in the hope that immunity can be induced by means of intradermal injections of trichophyton." Traub and Tolmach used two different preparations of trichophyton, but noted no difference in the results obtained. We might mention here that Fonseca's method of administering the vaccine is by *subcutaneous* injection, and no attempt at "desensitization" is made.

The work of Fonseca and his associates was first made known to us in August 1935, when we visited their

greatly because it seemed based on well-recognized immunological and bacteriological grounds. Fonseca described his vaccine as having antigenic properties which aroused antibody production and of achieving general immunity to involvement of the skin by a large variety of the fungi.

We attempted to make a preliminary survey. During the past eight months, fifty patients from private practice, suffering from fungus infections were given injections of the vaccine, in addition to the regular treatments by the usual local therapeutic methods (Table I). An earlier group of fifty other patients who had received similar local treatment but no vaccine, was studied for comparative results. Our object was to estimate, if possible, whether the use of "dermato-

mycol" shortened the time of treatment or resulted in more cures. The diagnosis in each case, aside from our clinical impression, was confirmed either by recovery of the fungi from the lesions, by culture, or by a positive intracutaneous test with "dermotricofitin" or with trichophyton (Lederle). In a certain number of cases there was a coexistence of other factors, such as a possible occupational dermatitis. Many of the patients had previously been treated by other physicians, indicating that some were of the types recalcitrant to therapy.

The usual routine of local treatment was carried out in all patients, i.e. wet dressings, mild fungicides, and in some cases fractional doses of Grenz or roentgen rays. A total of 504 subcutaneous injections of dermatomycol was given at

clinic at Rio de Janeiro, Brazil For several years they have used a vaccine for treating fungus infections They do not attempt to desensitize patients, because this procedure has proven either useless or harmful in their experience For purposes of diagnosis, "dermotricofitin,"—a filtrate of 300 strains of trichophyton, microsporum, achorion, endodermophyton, and epidermophyton—is used This filtrate is injected intradermally in the forearm and, when positive, the familiar tuberculin-like reaction appears within twelve to forty-eight hours as an erythematous macule, papule, or indurated area—varying in intensity from case to case or in the same case, according to the stage and severity of the fungus infection It is believed that fewer false negatives in fungus infections result, because of the large number of strains employed in the production of the filtrate

The preparation of this polyvalent trichophyton extract for treatment (dermatomycol, Brazilian) is of interest⁴ Three hundred strains of achorion, microsporum, trichophyton, epidermophyton, and endodermophyton obtained in the United States, Japan, Europe, and in North, South, and Central America have been employed The usual individual fungus is grown in aerobiosis in Sabouraud's glucose agar for one month The surface culture of mycelial growth is then killed by sulphuric acid and this mixture neutralized by sodium bicarbonate Each lot is of known constituency and the strength is determined by the total original mycelial weight content Phenol 0.4 per cent in concentration is used to maintain sterility of the vaccine Tests for potency are made on experimentally infected guinea pigs

The first paper on the use of this polyvalent vaccine appeared in 1931 Fonseca and Leao⁵ reviewed the work of numerous investigators who at various times used autogenous or stock vaccines in the treatment of fungus infections Results in general were disappointing, but further studies seemed worth while A vaccine was prepared by the method described above from 200 strains of organisms The therapeutic use of the vaccine and the results attained in two hundred cases was described In only thirty out of this group could a definite

conclusion be drawn, since it was impossible to follow the progress of most of their patients Cases were cited which showed excellent results, considering that many of them were scalp infections in children Unusual reactions were rare appearing as dyshydrosiform eruptions of the extremities

Motta,⁶ using Fonseca's preparation found it quite valuable and stated that ten to thirty injections were necessary for systematic cure of patients Some of the patients were also greatly improved by applying the vaccine solution locally

Fonseca⁷ stated again in 1934 that the use of his vaccine had enabled the original authors to abandon roentgenotherapy of the scalp in favus They also had been able to dispense with any local treatment in epidermophytosis and onychomycosis, since the infections responded to a greater or lesser number of injections of the polyvalent mycotic vaccine Their experience at that date is based on the use of the vaccine in hundreds of patients suffering from epidermophytosis, trichophytosis of the scalp and beard, microsporia, onychomycosis, and favus infections Reactions were reported as occurring in one to two per cent of cases as generalized erythema, pyrexia, or dyshydrosic reactions of the palmar and plantar surfaces of the hands and feet.

The nature of the antigenic properties of Fonseca's vaccine is now being studied and a recent report⁸ is available in the literature The method used in preparing the vaccine excludes the possibility of a protein being still present in it The classic reagents for detecting the presence of proteins have been found to be negative Tests for carbo-proteins have been found to be positive, and the vaccine is found to deviate polarized light from twenty to twenty-seven degrees, the vaccine thus demonstrating about the same deviating qualities as a one-half per cent glucose solution Preliminary clinical trials have shown that the carbohydrate fraction of the vaccine contains the therapeutic properties It is interesting to note that the active portion of the usual forms of trichophyton used in desensitization methods is considered to be contained in the polysaccharides⁹

The work of Fonseca and his associates with this new vaccine interested us

greatly because it seemed based on well-recognized immunological and bacteriological grounds. Fonseca described his vaccine as having antigenic properties which aroused antibody production and of achieving general immunity to involvement of the skin by a large variety of the fungi.

We attempted to make a preliminary survey. During the past eight months, fifty patients from private practice, suffering from fungus infections were given injections of the vaccine, in addition to the regular treatments by the usual local therapeutic methods (Table I). An earlier group of fifty other patients who had received similar local treatment but no vaccine, was studied for comparative results. Our object was to estimate, if possible, whether the use of "dermato-

mycol" shortened the time of treatment or resulted in more cures. The diagnosis in each case, aside from our clinical impression, was confirmed either by recovery of the fungi from the lesions, by culture, or by a positive intracutaneous test with "dermotricofitin" or with trichophyton (Lederle). In a certain number of cases there was a coexistence of other factors, such as a possible occupational dermatitis. Many of the patients had previously been treated by other physicians, indicating that some were of the types recalcitrant to therapy.

The usual routine of local treatment was carried out in all patients, i.e. wet dressings, mild fungicides, and in some cases fractional doses of Grenz or roentgen rays. A total of 504 subcutaneous injections of dermatomycol was given at

five to seven day intervals Eighteen patients had between ten and twenty or more treatments The average time of treatment was eight and one-half weeks per patient

Summary and Conclusions

Eight cases were discharged as clinically cured, twenty-seven had improved to such an extent that the patients felt it unnecessary to continue treatment, although many of them still had some slight evidence of the infection Fifteen patients are still under treatment. None of our vaccine cases were made worse by the treatment. In only one patient was the vaccine discontinued for any length of time This patient complained of severe headache on the day of the injection In a few cases, the arm used for repeated injections showed an area of edema and scaling with considerable pruritis

After studying the records of the year before, in which fifty cases in private practice were treated by local measures only, the only outstanding difference that

could be ascertained was that the patients who did not have the vaccine therapy averaged almost twice the length of time under treatment, i.e., thirteen and a half weeks as against eight and a half weeks

We feel that Fonseca's method of immunizing with a polyvalent fungus vaccine is based on better theoretic grounds than desensitization attempts which have had considerable trial by several investigators Our work with fifty patients over a period of eight months seems to indicate that dermatomycol shortens somewhat the course of fungus infections, but the results were not as striking as in the earlier reports in the literature.

Climatic and racial differences between the United States and Brazil may be factors bearing on these results The prevalent strains of fungi also differ from those in Brazil, but the large number of strains utilized in the preparation of the vaccine and the element of cross immunity effects in related fungi justify the use of the vaccine in further investigations

WELL WORTHY OF THE HALL OF FAME

How many people, of the countless thousands who benefit by artificial refrigeration, know that it was devised by a doctor? In the Hall of Fame in the national capitol at Washington each state is invited to place statues of its two most distinguished sons It is of interest to know that the State of Florida has one of its representatives, a physician, Dr. John Gorrie, the discoverer of artificial refrigeration, says *Southern Medicine and Surgery* The original machine by which artificial ice was first made about a hundred years ago is on exhibition at the Smithsonian Institute in Washington. It was for a long while an object of ridicule and he was unable to get funds for its commercial development. It

was not until thirty years after his death that one of the first artificial ice factories in the world was built in Apalachicola, his home. As a practicing physician he had to treat many cases of fever including malaria, which made him seek a way to procure ice for the control of the fever and for the comfort of his patients. It is of especial interest to know that unselfish seeking of a therapeutic aid for his patients and not the desire to make money led him to the discovery the importance of which to humanity in the economic and industrial world is just being fully appreciated. He understood the necessity for proper ventilation of the sick room and attempted air-conditioning in a crude way.

NEUROLOGICAL COMPLICATIONS OF SUBACUTE BACTERIAL ENDOCARDITIS

JOSEPHINE B NEAL, M D, HENRY W JACKSON, M D,
EMANUEL APPELBAUM, M D, *New York City*

Division of Applied Therapy, Bureau of Laboratories, Department of Health

In the course of subacute bacterial endocarditis, a variety of neurological complications may occur. This fact has received but little detailed consideration in the literature on the subject.

Libman¹⁻⁴ in his comprehensive studies of subacute bacterial endocarditis has frequently referred to various neurological manifestations, particularly hemorrhages of various types, cerebral embolisms, and abscesses, which he regards as areas of softening secondarily infiltrated by polymorphonuclears. He also refers to occasional cases of bacterial and non-bacterial meningitis, meningismus, and encephalitis.

This paper is based on a study of forty-one cases which we were called to see because the symptoms suggested to the attending physician a diagnosis of meningitis, encephalitis or poliomyelitis. The problem of differential diagnosis is at times fairly difficult. One must keep in mind the fact that embolic phenomena are of rather frequent occurrence in this disease. A lumbar puncture is, of course, indispensable. In this group of patients, the diagnosis of subacute bacterial endocarditis was established by the clinical picture and course, and confirmed in about a third of the cases by blood cultures. In certain cases necropsies were performed. All the blood cultures showed a non-hemolytic streptococcus, except one instance in which a gonococcus was found.

For clinical purposes we have divided the neurological complications into four groups and tables have been prepared summarizing the cases. This classification is not entirely satisfactory as certain symptoms may be present in two or more groups. Moreover, during the course of the disease the clinical picture may change. These groups simply indicate the striking features at some stage of the disease, particularly the onset.

The groups are as follows

I Cases with signs of Meningeal Irritation (Table I) These patients presented signs strongly suggestive of meningitis, and the diagnosis was made only by the examination of the spinal fluid. There were fifteen cases in this group. In nine instances a diagnosis of either serous or bacterial meningitis was made on the findings in the spinal fluid. Four of these were definitely bacterial meningitis, a non-hemolytic streptococcus being isolated from the spinal fluid. In one of these cases where organisms were not isolated, a bacterial meningitis was suspected on account of the low spinal fluid sugar. A meningitis due to a non-hemolytic streptococcus may be of very short duration.

Four cases had a serous meningitis. By the term serous meningitis, we mean that form of meningeal reaction in which there is a definite and often large increase in cells usually with a preponderance of polymorphonuclears, an increase in protein, normal sugar, and no organisms by smear or culture.

In four instances the signs of meningeal irritation were due to subarachnoid hemorrhage. Libman has pointed out that the subarachnoid hemorrhage is in most instances due to a rupture of a mycotic aneurysm and occasionally to a purpuric manifestation. It is usually impossible to find the exact point of bleeding at necropsy.

In two cases there were signs of meningeal irritation with a normal spinal fluid. This condition is designated as meningismus.

For the sake of brevity we are not describing cases illustrative of each of the four subdivisions. Indeed, the clinical picture in all is very much the same. The following case is selected as an example.

P. M., aged thirty-nine, was taken ill on November 28, 1932, with fever, headache, and insomnia. His past history revealed that he had poliomyelitis as an infant and "rheumatism" two years ago.

He was seen by one of us on December 29, at which time examination showed the patient to appear anemic and chronically ill. The temperature was 99° F., pulse ninety, and respira-

TABLE I—CASES WITH SIGNS OF MENINGEAL IRRITATION (GROUP I)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
J B	13½	M	Headache vomiting rigid neck, Kernig Brudzinski absent knee jerks apathy strabismus	Large increase polymorphonuclears. Protein greatly increased, Sugar absent, Culture Streptococcus viridans.	Bacterial meningitis.
V J	25	M	Headache vomiting apathy, rigid neck, Kernig	Culture Streptococcus viridans.	Bacterial meningitis.
S A	67	F	Stupor tremors	550 cells—polymorphonuclears. Protein increased. Sugar decreased, Culture Streptococcus viridans	Bacterial meningitis.
E S	44	F	Insomnia delirium rigid neck Brudzinski, paresis of legs, absent knee jerks	5 cells — mononuclears Chemistry normal Culture Streptococcus viridans.	Bacterial meningitis.
P M	39	M	Headache, insomnia rigid neck Kernig subconjunctival hemorrhage knee jerks exaggerated	Large increase polymorphonuclears. Protein increased Sugar diminished Culture Negative	Question of bacterial meningitis Blood culture non-hemolytic streptococcus.
B J	38	F	Vomiting, rigid neck, pupils fixed knee jerks diminished apathy	720 cells — 70% mononuclears Protein increased Sugar diminished	Bacterial meningitis. P M showed meningeal edema.
E P	6	F	Delirium Brudzinski	Large increase cells—90% polymorphonuclears. Sugar normal Culture Negative	Serous meningitis
R Y	17	F	Headache, rigid neck Kernig Babinski	2250 cells — polymorphonuclears. Protein increased. Sugar normal Culture Negative.	P M blood culture Gonococcus
R I	24	F	Headache, rigid neck left hemiplegia left ankle clonus, Babinski stupor	1650 cells—polymorphonuclears. Protein increased Sugar normal Culture Negative.	Serous meningitis, Blood culture Streptococcus viridans P M multiple infarcts. Subsiding meningitis.
S M	56	M	Headache vomiting apathy rigid neck, Kernig, strabismus nystagmus right Babinski knee jerks absent	Hemorrhagic	Subarachnoid hemorrhage.
M A.	24	F	Headache, vomiting irritability rigid neck, Kernig right Babinski knee jerks exaggerated	Hemorrhagic	Subarachnoid hemorrhage. Streptococcus viridans.
R. I	26	M	Headache vomiting apathy irritability rigid neck, Kernig	Hemorrhagic	Subarachnoid hemorrhage. P M Subarachnoid hemorrhage.
M M	16	F	Headache vomiting apathy	Hemorrhagic	Subarachnoid hemorrhage.
F P	3½	F	Vomiting convulsions rigid neck, Kernig left knee jerk absent	Normal	Meningismus.
A W	31	M	Headache vomiting rigid neck Kernig	Normal	Meningismus.

tion twenty There were murmurs over the aortic and mitral regions The lungs were clear The spleen was definitely palpable. There was a left subconjunctival hemorrhage. The reflexes were present. There was nuchal rigidity with positive Brudzinski and Kernig signs The spinal fluid was cloudy, showed a large increase of cells, mainly polymorphonuclears, a moderate increase in protein, diminished amount of sugar, and no organisms by smear or culture. The blood culture was positive for a non-hemolytic streptococcus. The diagnosis of subacute bacterial endocarditis was therefore established. It was felt also that the patient had a bacterial meningitis, although no organism were recovered from the spinal fluid

Following spinal drainage there were marked improvement in the meningeal complication and the spinal fluid became normal The patient's general condition, however, became progressively worse, and he died in uremia on February 6, 1933

II Cases with Paralysis (Table II) Paralysis is perhaps the most common neurological complication in subacute bacterial endocarditis It was the outstanding

manifestation in fifteen of our cases and it was also a feature in cases in other groups It was usually of the upper motor neuron variety resulting in a hemiplegia or hemiparesis, although in three instances the involvement appeared to be of the lower motor neuron type. We have no necropsy material illustrative of cord lesions. It is to be noted that even in central lesions, the paralysis may at first seem to be flaccid. It is therefore obvious that the diagnosis of poliomyelitis is sometimes suspected The paresis or paralysis may be of short duration or there may be a transitory paresis on one side followed by a paralysis on the other side. In one instance there was a spastic quadriplegia In our series both sides were equally involved

The exact nature of the lesion can only be inferred, aided by the spinal fluid findings, except in those cases where a necropsy was obtained. It may be assumed that the primary lesion is an embolism, but following the embolization various pathological

developments may occur These will be described in the section on pathology

The spinal fluids in these cases with paralysis showed great variations In some instances the findings were normal In others there was a slight to large increase in cells, with a predominance of either polymorphonuclears or mononuclears, a slight increase in protein, and usually a normal sugar In still others the spinal fluid was hemorrhagic None of the fluids showed the presence of organisms

Since the majority of the cases in this group began with a hemiplegia, it may be of interest to describe a case in which at the onset the diagnosis was poliomyelitis

J M, aged twenty-one, became ill on October 4, 1931, with chills, fever, headache, sore throat, and pain in the back of his neck. His past history showed that he had had rheumatic fever complicated by a cardiac lesion

On physical examination, there was nuchal rigidity, positive Kernig sign, and paralysis of his right arm The heart presented the signs of a double mitral valve lesion A lumbar puncture performed on October 6, yielded a clear fluid, which showed twenty-eight cells,

a slight increase in protein, normal sugar, and no organisms

On October 7 and 8, there were convulsive seizures of the right side followed by an extension of the paralysis On this date there appeared a crop of petechiae over his extremities

October 11, the spinal fluid was xanthochromic.

The patient died on October 12 A necropsy showed chronic aortic, mitral, and tricuspid valvulitis with superimposed vegetative endocarditis The brain showed hemorrhagic infarction of left frontal lobe and smaller infarcts elsewhere throughout the brain substance The spinal fluid was blood tinged. There were also multiple infarcts in the other viscera.

III Cases with Encephalopathy (Table III) In this group of six cases, the patients presented a clinical picture resembling encephalitis Delirium, somnolence, stupor, blurring of vision, diplopia, vertigo, limitation of ocular movements, muscular twitching, masked facies, and increased salivation were among the striking symptoms Some of the cases also had signs of meningeal irritation, changes in the reflexes, paralysis blurring of the disks, and optic neuritis

TABLE II.—CASES WITH PARALYSIS (GROUP II)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
M H	20	F	Vomiting delirium stupor rigid neck, Kernig pupils dilated no reaction spastic quadriplegia, knee jerk exaggerated, ankle clonus, Babinski, abdominals absent.	No tap	Blood culture Streptococcus viridans
M M	13	F	Headache vomiting rigid neck, pupils dilated, no reaction reflexes absent paresis right arm and leg	Normal	
M C	27	M	Headache, vomiting coma, knee jerk absent right hemiplegia.	Slightly hemorrhagic. Protein increased Sugar normal.	Blood culture Streptococcus viridans
G G	18	F	Slight rigidity of neck, Kernig transitory paralysis of left arm, knee jerks absent.	No tap	
H R.	39	F	Delirium, left spastic hemiplegia, left biceps and patella reflexes exaggerated, left Babinski left abdominals absent.	450 cells—polymorphonuclears. Protein increased Sugar normal	
J L.	14½	F	Headache, right hemiparesis with aphasia, deep reflexes greater on right than on left, abdominals greater on left than on right right Babinski	No tap	
B B	4	F	Slight stiffness of neck, Kernig transitory paresis of left leg.	Fluid blood tinged Protein increased. Sugar normal	Blood culture Streptococcus viridans.
R. C	19	F	Headache, stupor rigid neck, Kernig transitory left hemiparesis, later right hemiplegia with aphasia.	Hemorrhagic	
J M	21	M	Headache rigid neck, Kernig diminished reflexes, paresis of right arm followed by right hemiplegia.	First 28 cells. Sugar normal Protein increased. Later xanthochromic.	P M hemorrhagic infarct left frontal lobe. Multiple emboli
H R.	13	M	Apathy rigid neck, Kernig optic neuritis, right hemiplegia with aphasia, deep reflexes greater on right than on left, right Babinski.	80 cells — mononuclears. Protein increased. Sugar normal	
L. H.	41	F	Headache, disturbance of speech right hemiparesis, deep reflexes exaggerated on right, right Babinski.	Practically normal	
G T	8	M	Headache, vomiting coma, rigid neck, Kernig, contracted pupils, spastic paralysis of left leg left Babinski.	Hemorrhagic	
M T	24	F	Left hemiplegia at onset	No tap	
M McP	16	F	Headache, left hemiplegia, signs of meningeal irritation at first.	Large increase in cells — 60% mononuclears. Protein increased. Sugar slightly diminished.	Had second similar attack.
M H	3½	M	Slight rigidity of neck, Kernig paresis of both lower extremities, knee jerks absent, pupils sluggish to light	105 cells — mononuclears. Protein increased. Sugar normal.	

The spinal fluid findings showed variations similar to those described in the preceding group

Whether the symptoms were due to encephalomalacia, cerebral abscess, encephalitis or various forms of intracranial hemorrhage is a matter of conjecture. Of course a uniformly bloody fluid would prove the presence of hemorrhage, but this might or might not be combined with other lesions

by a cloudy spinal fluid, containing more than 1000 cells, ninety-two per cent polymorphonuclears. Accordingly, she received four doses of antimeningococcic serum intraspinally. However, no organisms were demonstrated and the spinal fluid sugar had remained normal. By July 16, the entire spinal fluid examination was practically normal, but the patient's clinical condition had not improved and certain new features had developed. Her mental reactions were very much retarded. She was stuporous

TABLE III—CASES WITH ENCEPHALOPATHY (GROUP III)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
M F	29	F	Delirium stupor contracted pupils, optic neuritis right reflexes exaggerated left reflexes diminished, abdominals absent.	Hemorrhagic	Blood culture Streptococcus viridans.
A E	62	F	Headache vertigo blurring of vision, stupor, rigid neck, Kernig pupils sluggish to light, marked spasticity deep reflexes exaggerated on right, bilateral Babinski slight hemiparesis on right, abdominal reflexes absent petechiae.	52 cells — mononuclears. Protein increased Sugar normal	
F N	29	F	Headache, stupor rigid neck and Kernig at onset transitory ankle clonus, knee jerks increased, blurring of discs.	Normal	Blood culture Streptococcus viridans
M L	24	F	Headache stupor, rigid neck, Kernig blurring of vision at onset left knee jerk greater than right, ankle clonus on left, pupils sluggish to light and accommodation, retarded mental reactions, mask like expression, increased salivation.	Early 1000 cells — polymorphonuclears. Sugar normal. Later, fluid normal.	Blood culture Streptococcus viridans
P M	12	F	Headache vomiting stiffness of neck, drowsiness, twitching of left arm, diplopia	200 cells — mononuclears Protein increased Sugar normal	
E H	8	F	Headache, vomiting diplopia, knee jerks absent	Hemorrhagic	

TABLE IV—COMBINED FORMS (GROUP IV)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
J F	13½	M	Rigid neck, Kernig hyperesthesia, right knee jerk exaggerated left knee jerk absent, paresis of right leg, paralysis of right deltoid, difficulty in swallowing	Protein increased Sugar diminished. Culture Non-hemolytic streptococcus.	Blood culture Non-hemolytic streptococcus. Bacterial meningitis and paralysis.
L P	14	M	Headache vomiting stupor pupils contracted sluggish to light, deep reflexes absent on right, paralysis of right arm and leg left facial palsy, dysphagia.	Cells greatly increased — polymorphonuclears. Protein increased Sugar normal	Blood culture Streptococcus Paralysis and serous meningitis
L D	10	M	Headache vomiting apathy convulsions rigid neck, left hemiplegia.	Moderate increase in cells — mononuclears Proteins increased. Sugar normal	Paralysis and encephalopathy
N H	50	M	Rigid neck, stupor Kernig on left pupils dilated and fixed, right hemiplegia knee jerk increased on left, Babinski on right.	Cells greatly increased — polymorphonuclears. Protein increased. Sugar absent.	Blood culture Streptococcus viridans. P M Emboli of brain and softening of left internal capsule
D C	20	M	Headache vomiting rigid neck, Kernig nystagmus, paralysis of left face and arm numbness and tingling in arms and face	1800 cells — polymorphonuclears	Blood culture Streptococcus viridans. Paralysis and serous meningitis

The following case history is fairly typical of this group

M L, aged twenty-four, became suddenly ill on July 1, 1930, with headache, fever, and blurring of vision. She was seen in consultation on July 16. It was then learned that she had an endocarditis of long standing, following rheumatism. At the beginning of her present illness, stiffness of the neck and a positive Kernig sign developed, suggesting a meningitis, and this diagnosis seemed to be confirmed

at times. Her face had a mask-like expression, and there were periods of increased salivation. The extraocular movements upward and downward were limited. The reactions of the pupils were sluggish to light and accommodation. The abdominal reflexes were diminished. The left patellar reflex was more active than the right and there was ankle clonus on the left. At this time, therefore, she presented the clinical picture of an encephalitis, and in addition there was the history of visual disturbance at the onset of the illness. There were the signs of

a double mitral lesion of the heart and the liver was enlarged. The temperature was 104°F. In view of all the developments, it seemed quite certain that the various neurological manifestations were due to emboli from a subacute bacterial endocarditis. This diagnosis was later confirmed by two blood cultures positive for the streptococcus viridans. The patient died September 17.

IV Combined forms (Table IV) In this group we have listed five cases in which the symptomatology was particularly complex. It is true that in the other groups there was often not a clear-cut and consistent clinical picture but usually one set of symptoms predominated. In these cases, however, the symptoms seemed to be distributed more or less equally over two or more groups. It is obvious that signs of meningeal irritations are present in a large percentage of all the cases.

In all five of these cases there was some form of paralysis. In two instances there were also symptoms of encephalopathy. In one of these there was evidence in the spinal fluid of a meningitis. The nature of this it is difficult to state, since although no organisms were found, the spinal fluid sugar was absent. Moreover at necropsy no definite evidence of meningitis was noted in the gross. Unfortunately a microscopic examination was not made.

In two other cases a serous meningitis was superimposed and in the fifth case there was a definite bacterial meningitis.

D. C., aged twenty, had been running a low grade fever for some time. On February 5, 1932 he became suddenly worse with headache, vomiting, and a rise in temperature. Rigid neck and positive Kernig sign and paralysis of the left face and arm developed.

A lumbar puncture on February 6 showed a cloudy fluid with about 2000 cells, polymorphonuclears, and an increase in protein. No organisms were demonstrated and the sugar was not determined. Antimeningococcic serum was given at once intraspinally. On this date he complained of numbness and tingling in the left arm and face. This was of short duration. The patellar reflexes were diminished and there was a nystagmus. The heart showed evidence of valvular lesions with murmurs over the apex and base. A positive blood culture for streptococcus viridans was later obtained. The patient died late in March. This case showed a combination of paralysis and serous meningitis.

Most of the changes found in the brain are the result of embolization of a cerebral vessel or vessels. This leads in most instances to the development of a single or multiple infarcts, which may involve any region of the brain. The areas of necrosis vary in degree from slight soft-

ening to complete destruction of the brain tissue, resulting in cavity formation. Not infrequently the brain substance in the infarcted region is of semifluid consistency. The areas of infarction are occasionally hemorrhagic, and are frequently surrounded by a narrow zone of brownish-yellow pigment. A localized hemorrhagic pachymeningitis is not infrequently superimposed on these areas of softening. Occasionally an infarct may heal. It is to be noted that the embolized or throm-

Fig 1 Destruction of a portion of the vessel, with cellular infiltration. Note break in elastica

bosed vessel can rarely be determined in the gross. Microscopically, however, one can frequently find a necrotizing arteritis, with destruction of varying portions of the vessel wall, thrombus formation, cellular infiltration, and intimal proliferation (Figs 1, 2, 3).

The septic emboli may occasionally cause the formation of large or small brain abscesses. Libman, as previously pointed out, does not regard these as abscesses in the true sense of the word, but as areas of softening, secondarily invaded by leukocytes.

If the septic embolus involves a vessel near the surface of the brain or in the meninges, it may lead to the development

The spinal fluid findings showed variations similar to those described in the preceding group

Whether the symptoms were due to encephalomalacia, cerebral abscess, encephalitis or various forms of intracranial hemorrhage is a matter of conjecture. Of course a uniformly bloody fluid would prove the presence of hemorrhage, but this might or might not be combined with other lesions

by a cloudy spinal fluid, containing more than 1000 cells, ninety-two per cent polymorphonuclears. Accordingly, she received four doses of antimeningococcus serum intraspinally. However, no organisms were demonstrated and the spinal fluid sugar had remained normal. By July 16, the entire spinal fluid examination was practically normal, but the patient's clinical condition had not improved and certain new features had developed. Her mental reactions were very much retarded. She was stuporous

TABLE III.—CASES WITH ENCEPHALOPATHY (GROUP III)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
M F	29	F	Delirium, stupor, contracted pupils, optic neuritis, right reflexes exaggerated, left reflexes diminished, abdominals absent.	Hemorrhagic	Blood culture Streptococcus viridans.
A. E	62	F	Headache, vertigo, blurring of vision, stupor, rigid neck, Kernig, pupils sluggish to light, marked spasticity, deep reflexes exaggerated on right, bilateral Babinski, slight hemiparesis on right, abdominal reflexes absent, petechiae.	52 cells — mononuclears. Protein increased. Sugar normal.	
F N	29	F	Headache, stupor, rigid neck and Kernig at onset, transitory ankle clonus, knee jerks increased, blurring of discs.	Normal	Blood culture Streptococcus viridans.
M L	24	F	Headache, stupor, rigid neck, Kernig, blurring of vision at onset, left knee jerk greater than right, ankle clonus on left, pupils sluggish to light and accommodation, retarded mental reactions, mask like expression, increased salivation.	Early 1000 cells — polymorphonuclears, Sugar normal. Later, fluid normal.	Blood culture Streptococcus viridans.
P M	12	F	Headache, vomiting, stiffness of neck, drowsiness, twitching of left arm, diplopia	200 cells — mononuclears. Protein increased. Sugar normal.	
E H	8	F	Headache, vomiting, diplopia, knee jerks absent.	Hemorrhagic	

TABLE IV.—COMBINED FORMS (GROUP IV)

Name	Age	Sex	Outstanding neurological symptoms	Spinal fluid findings	Remarks
J F	13½	M	Rigid neck, Kernig, hyperesthesia, right knee jerk exaggerated, left knee jerk absent, paresis of right leg, paralysis of right deltoid, difficulty in swallowing	Protein increased. Sugar diminished. Culture Non-hemolytic streptococcus.	Blood culture Non-hemolytic streptococcus. Bacterial meningitis and paralysis.
L P	14	M	Headache, vomiting, stupor, pupils contracted, sluggish to light, deep reflexes absent on right, paralysis of right arm and leg, left facial palsy, dysphagia.	Cells greatly increased — polymorphonuclears. Protein increased. Sugar normal.	Blood culture Streptococcus viridans. Paralysis and serous meningitis.
L D	10	M	Headache, vomiting, apathy, convulsions, rigid neck, left hemiplegia.	Moderate increase in cells — mononuclears. Proteins increased. Sugar normal.	Paralysis and encephalopathy
N H	50	M	Rigid neck, stupor, Kernig on left, pupils dilated and fixed, right hemiplegia, knee jerk increased on left, Babinski on right	Cells greatly increased — polymorphonuclears. Protein increased. Sugar absent.	Blood culture Streptococcus viridans. P M Emboli of brain and softening of left internal capsule
D C	20	M	Headache, vomiting, rigid neck, Kernig, nystagmus, paralysis of left face and arm, numbness and tingling in arms and face.	1800 cells — polymorphonuclears	Blood culture Streptococcus viridans. Paralysis and serous meningitis.

The following case history is fairly typical of this group

M L, aged twenty-four, became suddenly ill on July 1, 1930, with headache, fever, and blurring of vision. She was seen in consultation on July 16. It was then learned that she had an endocarditis of long standing, following rheumatism. At the beginning of her present illness, stiffness of the neck and a positive Kernig sign developed, suggesting a meningitis, and this diagnosis seemed to be confirmed

at times. Her face had a mask-like expression, and there were periods of increased salivation. The extraocular movements upward and downward were limited. The reactions of the pupils were sluggish to light and accommodation. The abdominal reflexes were diminished. The left patellar reflex was more active than the right and there was ankle clonus on the left. At this time, therefore, she presented the clinical picture of an encephalitis, and in addition there was the history of visual disturbance at the onset of the illness. There were the signs of

hemorrhagic pachymeningitis The various forms of intracranial hemorrhage are probably due in most instances to a rupture of a mycotic or embolic aneurysm Occasionally injury to the capillaries as a result of the infection or perhaps as an expression of a blood dyscrasia may be responsible for the bleeding Libman was the first to stress these facts It is to be noted that one can practically never find the blood vessel involved in the bleeding process

Other changes occasionally found are edema of the brain and varying degrees of congestion of the vessels on the surface of the brain These findings may account for the clinical pictures of meningismus and transitory paresis

Summary

We have briefly described the neurological complications in forty-one cases

Discussion

DR. EMANUEL LIBMAN, New York City—It would have been advantageous, I believe, for Dr Joseph H² Globus to have opened the discussion, because being so great an expert in neuropathology, he could have paved the way for a clinical discussion by myself It is now necessary for me to go into a short statement of pathological data which can be mainly derived from the literature. Dr Neal and her colleagues have made a clinical classification that appears to me to be practical According to Kimmelstiel, a localized or diffuse meningoencephalitis is rather common in subacute bacterial endocarditis, having found it in eight of eleven cases The lesion may be ischemic in nature, or inflammatory, or both

Lesions of the arteries are very frequent and varied. Gross changes are produced by embolisms, embolic aneurysms, and thromboses Embolic aneurysms are due to lodgement of pieces of vegetation, or of clumps of bacteria, in the walls of the arteries Such aneurysms may rupture, and hemorrhage result But hemorrhage may occur from a necrotic area in the wall, without the development of an aneurysm. Small inflammatory areas may be found in the wall, due to bacterial infection.

There is another lesion of the arteries in which bacteria are not found. It consists of an arteritis due to an apparently toxic (allergic?) effect of the bacterial endocardial lesions There may be found necrosis of the wall, periarterial changes, intimal

proliferation and thrombosis It is important to remember that closure of vessels may arise from such thrombotic lesions and are not always embolic in origin

of subacute bacterial endocarditis These patients presented, in the main, signs of meningeal irritation, paralysis of various types, and features of encephalopathy The fundamental lesion was usually an embolization of a cerebral vessel or vessels which subsequently led to the development of cerebral infarction, abscess, bacterial or serous meningitis, and the various forms of intracranial hemorrhage

We wish to express our appreciation to Dr Douglas Symmers and to Dr Lewis D Stevenson for permitting us to use pathological material from Bellevue Hospital

There may be multiple areas of softening due to closure of vessels, and miliary or occasionally abscesses These abscesses are not true primarily purulent foci, but are probably brought about by autolysis and secondary polynuclear invasion in infarcted areas I was glad to hear Dr Neal speak of possible involvement of the spinal cord In one case, a funicular myelosis has been described, and in animal experiments, Kimmelstiel produced not only endocarditis, meningoencephalitis infarction, and abscesses, but also funicular myelosis

I would like to emphasize what Dr Neal said of the cases in which the cerebrospinal fluid shows polynuclear cells, with or without the presence of streptococci There is a polynuclear aseptic meningitis in cases of subacute bacterial endocarditis, and a polynuclear streptococcal meningitis It is to be remembered that the latter also occurs without the presence of endocarditis

As regards blood fluids, they may be due to rupture of an embolic aneurysm, or to a hemorrhagic tendency alone Such a condition need not be fatal In 1918 I described a simple method for determining whether an aspirated bloody cerebrospinal fluid was due to traumatism or not, and I have found this method often to be of value Within a few hours after hemorrhage (as

Fig 2 Thrombosed artery with some destruction of the arterial wall. There is also edema and necrosis of surrounding brain substance.

of bacterial meningitis, which is occasionally of short duration. In these cases one rarely observes a purulent secretion but rather a marked injection of the meninges which microscopically show the typical cellular exudate (Fig 4). Congestion of the meninges may also be caused by a serous meningitis which is not an infrequent accompaniment of infarction or abscess of the brain.

One of the most striking of pathological findings is the presence of intracranial hemorrhage, most commonly of the subarachnoid type. It may, however,

Fig 3 Intimal proliferation with recanalization.

Fig 4 Meningitis with the typical cellular exudate.

occur in the brain parenchyma, particularly the internal capsule, and occasionally in one of the ventricles. Numerous small hemorrhages in the brain substance are not rare. We have already mentioned the frequent occurrence of

URETHRAL DISEASE IN WOMEN

An Evaluation of the Present Knowledge

ARTHUR H PAINE, M D, *Rochester*

The study of the anatomy and the pathology of the female urethra and bladder neck, and the appreciation of the importance of the symptom complex and misery to the sex from disorders of these structures, has not kept pace with the signal advance in upper urinary tract diseases and the lower tract of the male

The lesions of the lower male tract are predominantly obstructive and menacing to health and life, and have been accorded intensive study since the earliest history of urology. Disorders of the urethra and bladder neck in the female relatively seldom produce secondary pathological inroads upon the general health, and rarely menace life.

To appreciate the reasons for this tardiness one need but consider the evolution of urology. Formerly most of the urological clinics and teaching centers, and many prominent genitourinary surgeons, had nearly a total male clientele. Female urological cases remained in the hands of the general practitioner, the surgeon, and the gynecologist.

The evolution of the cystoscope has been a factor in the delay. The popular instrument having been the right angle lens of the Brown-Buerger type, urethral pathology was not visible. As one speaker has stated "the female urethra has been considered merely a structure upon which to rest a cystoscope during bladder observation and urethral catheterization."

With the increase in the number of women attending urological clinics, and their reference to the urological service in hospital and private practice, and with the advent of fore-oblique lenses and increased use of the Kelly type of open scope, an active interest and study of urethral and bladder neck pathology have been stimulated. As a result, an appreciation of the vast amount of suffering from this source is beginning to be realized. The necessity of further study is recognized, and much important patho-

logical and clinical information is being collected.

Methods of diagnosis have been extended beyond the cystoscope to the use of bulb bougies, Hegar dilators, cystometers, urethrograms, and cystograms.

The two volume work, *History of Urology* (1933), heralds all the important advances in urology, but no allusion is made to any study or advancement in the treatment of so common a source of misery as the female urethra, yet, two decades ago, Bugbee, Bransford Lewis, Arthur Chute, and a few others called attention to the prevalence and importance of urethral disease in women. It has remained necessary for the work of Einar Thomsen, Van Dusen and Luney, and Crabtree on anatomy of the female urethra and trigone, and the work of Stevens, Folsom, Pugh, Furniss, and Ormond on pathology, clinical manifestation, and treatment in the past few years, to stimulate interest and direct serious consideration to the subject.

Anatomical studies have clarified and added to the knowledge of the supports and closing mechanism of the female bladder. Studies of the parous bladder and urethra by combined urethrography, cystography, and cystoscopy have suggested improvement in methods and technique for the correction of cystocele and operative procedure to control incontinence. A definite anterior curvature and a fairly sharp angulation at the upper third of the urethra has been demonstrated. The perivaginal fascia, one of the chief supports of the bladder, is frequently injured, and as a result, the curvature and angulation of the urethra and its relation to the trigone is altered.

The diagnosis, understanding of clinical manifestations, and application of accurate therapy to any disease must depend upon a thorough knowledge of the gross and histological anatomy and the pathological changes in the structures involved.

*Read at the Annual Meeting of the Medical Society of the State of New York
New York City, April 29, 1936*

early as three hours and perhaps less) there is apt to develop a lymphocytosis in the fluid. If one makes a differential leukocyte count of the fluid and at the same time of the blood, the former may be found to contain twenty-thirty per cent more lymphocytes than the latter. Sometimes when a meningeal reaction has already taken place, a secondary bleeding may be suspected if there develops suddenly a sharp pain above the eye.

Symptoms due to an existing encephalitis may be very marked. In one instance we had reason to suspect that the patient was suffering from subacute bacterial endocarditis and epidemic encephalitis (during an epidemic). Dr Neal has referred to the rather frequent slowing up of the mentality and a tendency to a mask-like expression of the face. I would also like to emphasize tremor as a symptom, especially tremor of

the hands. I do not know that it necessarily means striatal involvement. Cases of endocarditis have been described with definite lesions in the corpus striatum, characterized by rigidity and tremor, and the absence of pyramidal symptoms. Involvement of the substantia nigra has been described, with somnolence as the outstanding symptom. Several cases of hypophyseal cachexia have been noted, due to embolization of the anterior lobe of the hypophysis.

A hemiplegia may begin intermittently. For instance, it may happen that a patient goes to his place of work in the morning and comes back in the afternoon with a hemiparesis, is all right the next morning, and then develops paresis in the afternoon, which may go on to complete hemiplegia. The hemiplegia in this disease need not be permanent. Stahl described five cases in which it disappeared in four to fourteen days.

SOCIALIZED MEDICINE NOT WANTED BY LABOR

What the self-respecting laboring man wants is the right to choose his own personal physician, and a wage sufficient to pay the bill. He has found by unfortunate experience that medical attendance supplied by paternalistic schemes is more likely than not to turn out unsatisfactorily. That is the essence of an intelligent article by Mr James H. Anderson, editor of the *Kansas City Labor News*, and published in the October 10 issue of the *Jackson County Medical Journal* (Kansas City). He says:

Free medical care, including hospitalization, clinics and medicine, supported and maintained by states and local communities, through a general taxation, has to a certain extent existed for ages. Such care and such hospitalization is essential and commendable and should be continued, but such free service was created for the purpose of giving aid and succor to those financially unable to pay their own way. I do not believe, and I think you will agree with me, that it was not created or intended for those who were or are able to pay.

Labor is not in favor of charity, the dole or relief for those who are able to work and earn a decent pay, nor in favor of so-called free medical care, whether furnished by corporations employing groups of men and women, or whether supported and maintained by federal, state or local communities, because experience has taught us that such service is not always very satisfactory, and in the long run those receiving such service have to foot the bill anyway, either through deduction in pay or through taxation.

It has been found that physicians for instance, furnished by employers, or even by labor and fraternal organizations, as a general rule do not render as satisfactory service

as those privately employed by the patient himself.

Men of labor as well as others, in case of sickness or disability, prefer to choose their own medical attendant in whom they have confidence and who they know will use all of his knowledge, science and ability for a speedy recovery.

I do not believe that labor looks with much favor on compulsory insurance. *** Opportunity to work and to earn is the cherished hope of all members of organized labor. The American Federation of Labor was founded for the purpose of obtaining for its members decent wages, reasonable working hours and sanitary working and living conditions.

What labor wants is a decent wage—a wage sufficient to meet the requirements of the American standard of living, a wage that will provide sanitary housing, wholesome food, decent clothing, enough to keep the children in school instead of in the sweat shop, clean amusements, medical care, premiums of health, accident and life insurance, and all those other things which are so essential to the well-being of mankind, besides some kind of social security that will care for the aged.

Now, to the medical profession I will say this in all candor and sincerity that, if the working people were permitted to work and would receive decent wages, if the unemployment of those able and willing to work was reduced to a minimum, they could and would, when sick or disabled, be able to employ and pay their own medical attendant, buy their own medicine and pay their own hospital bills. Physicians and surgeons would receive their just and equitable compensation for their services, hospital bills and medicine would be paid by the patients themselves without federal, state or local aid and without taxation being placed on the general public.

Helper and Scott have recently shown that ninety-nine per cent of a series of 694 infants and children had pus cells in voided urine, and catheterization ruled out pyuria of kidney and bladder origin in all but thirteen per cent of cases. Thus, it may be assumed vulvar contamination and the urethra are the source of pyuria in the vast majority of cases. It is true that the diagnosis of pyelitis in female infants and children is frequently made solely upon the finding of pyuria from voided specimens. The routine use of the catheter to check upon voided specimens will greatly reduce the number of diagnoses of pyelitis, and direct attention to meatal stenosis, urethritis, and urethrotrigonitis in female children. Those who see a large number of children from an urological aspect are convinced that congenital and acquired disease of the infantile and juvenile urethra are not rare, and account for much urological morbidity. W E Stevens has recently studied the literature and enlightened us on the occurrence of congenital malformations of the female urethra. It is reasonable to assume Dr Stevens' contribution only suggests the frequency of congenital defects when one considers the large number of unrecognized minor defects, as stenosis of the meatus and hypospadias. It is well-known that congenital defects predispose to pathological changes, and this is especially true of tubular structures, and the urinary tract in particular, since stasis is engendered favoring infection.

In early and middle adult life during the period of greatest sexual capacity, and the menstrual and child bearing activity, the female urethra is especially prone to trauma, congestion, and infection. Bladder dysfunction will manifest disorders of the urethra and trigone by frequency, dysuria, and pain. These symptoms should be elicited in history taking, and thoughtfully evaluated and investigated. A grain of prevention at the onset may prevent years of annoyance or suffering, and advanced pathological changes in later life.

Elderly cases in either sex are still considered in both the lay and professional minds to have a physiological excuse for bladder dysfunction. Just as early manifestations of prostatic obstruction are condoned as senile changes to be

expected and tolerated, so are the distressing manifestations of urethrotrigonitis in elderly women accepted as a penalty of attaining ripe old age.

As urethritis in the male is predominantly gonorrheal, the opposite is true in the female. Gonorrhea is undoubtedly the cause of chronic urethral diseases and stricture in the female, but the relative number of cases due to this disease is very small.

Discharges from vaginitis, cervicitis and puerperal infection, carelessness about vulvar hygiene and menstrual napkins, contamination other than gonorrheal by coitus, and by feces, afford a varied and fertile source of retrograde urethral infection.

The history of attacks of pyelitis, possibly unrecognized at the time of their occurrence, or attacks of acute urethrotrigonitis, may be elicited by careful questioning to supply the etiology in cases of chronic urethritis.

No conclusive studies of the bacteriology of female urethritis have been made. It is obvious how difficult this is. The urine obtained by catheter from the bladder is often sterile. Contamination from the meatus would often vitiate swab or loop cultures, and organisms from the surface of the mucosa might not represent the true infecting agents in the deeper structures.

Symptoms

The symptoms vary with the pathology. Frequency is the most common and constant symptom. Many patients are quite incapacitated for work or social activity. It is chiefly by day, when active upon the feet, and most distressing during the early forenoon, apparently responding to the changes in blood supply and the alteration of the position of the trigone and urethra incident to the change from recumbent to standing position.

Nocturia may be absent. When present, lesions of the upper urethra trigone or bladder should be suspected. Like day frequency, it is often most pronounced immediately upon retiring, as the irritated urethra and trigone respond to depletion of congestion, and ptosed structures recede with recumbency.

A frequent symptom is a sensation in

The embryological origin and homologies of the entire female urethra and the male prostatic urethra, are not agreed upon at present

However, it is true that the anterior two-thirds of the urethra is lined with squamous epithelium, and is credited with being of ectodermal origin. Therefore, it seems contradictory that Skene's tubules and the paraurethral glands are accepted as homologues of the prostatic ducts and tubules which are of entodermal origin. The study of embryos of both sexes up to 144 mm, shows the presence of identical glandular structures at the base of the trigone and around the sphincteric region. These predominate in the male and form the prostatic gland structures of the adult male. They vary in frequency of occurrence in the female embryo, and undoubtedly persist to a greater or lesser degree in the upper-third of the adult female urethra and caudad extremity of the trigone, since this portion of the female urethra is of entodermal origin and lined with transitional epithelium similar to and merging with that of the trigone.

Some consider that the structures described, and the histological specimens exhibited purporting to be such glands, show only epithelial inclusion in chronic inflammatory hyperplastic tissue, and are of the nature of Brunn's nests. The acini are interpreted as central cystic degeneration. The studies of Folsom and Chwalla would seem to definitely establish the presence of these glands. The pathology of the upper urethra and trigone may be explained by accepting the presence of these glands.

That the anterior two-thirds of the urethra is of ectodermal origin and lined with squamous epithelium, the presence of Skene's tubules near the meatus, and a similar group on the floor dipping down towards the anterior vaginal wall, are undisputed.

At the meatus and in the anterior two-thirds of the urethra, certain definite pathological changes occur, *viz*

1 Congenital stenosis

2 Acquired infiltration and stricture, the products of chronic inflammatory processes involving the glandular structures in the submucosa.

Most writers stress the prevalence of stricture, estimating its presence in thirty-

seven per cent of all urinary disturbances, and state that eighty-five per cent of such strictures occur at the meatus. Congenital discrepancy in caliber at this point is undoubtedly very common in females, as it is in males. Strictures at the meatus are more commonly due to congenital atresia than to an inflammatory process. A congenitally small meatus plays the role of stricture elsewhere in the canal, the retention of a drop or fraction thereof of urine with consequent dribbling on the meatus and water-logging of the mucosa immediately behind it. This retention is actually stasis. It predisposes to infection. When infection occurs, drainage is further retarded by swelling and the gland structures and submucosa are invaded. Finally proliferative granular urethritis supervenes, and the so-called caruncle, stricture, or both, are present at the meatus.

3 Hyperplasia with extrusion thru the meatus of the urethral mucosa

4 Caruncle. This term is unfortunate as it means only a piece of flesh, and assumes all protruding growths from the meatus to be neoplasms and demanding the same consideration. Caruncle is peculiar to the lower portion of the female urethra. Its origin is believed to be Skene's tubules. Three types are recognized: (a) Granuloma which is a hyperplastic, chronic inflammatory product, the result of chronic urethritis, (b) papillary angioma, and (c) telangiectatic mucoid polyp, both new growths. Histologically, glandular tissue, newly formed blood vessels, and inflammatory infiltration are found.

5 Suburethral abscess and diverticulae, sometimes containing calculi

6 Carcinoma

The pathology, like the origin and structure of the upper-third of the urethra and sphincter region, differs from the lower urethra. Here is found hyperplasia, infiltration with fibrosis, polypoid and cystic degeneration.

Various writers state the frequency of urethral diseases as sixty per cent of all women consulting a physician as gynecological cases, and eighty per cent of all female urological cases.

The profession is still culpable in failure to give due or serious consideration to varying degrees of bladder dysfunction in both sexes, at all ages. In infancy and childhood, enuresis, frequency, and dysuria are passed over lightly. The former with the comforting assurance that the child will outgrow it, and the latter two with the blanket diagnosis of pyelitis.

one-third may show dilated vessels, polypoid or cystic degeneration, and a corrugated, irregular, dusky outline of the internal sphincter instead of the smooth, regular, glistening, pink mucosa of the normal

Actual heaping up of tissue at the sphincter floor, with a sharp declivity to the trigone, is not as rare as the literature would indicate. Trabeculation and residual urine may accompany this finding. Apparently a true bladder neck contracture exists.

Differential Diagnosis

Excepting pregnancy, very large or impacted fibroids, pressure of the uterus upon the bladder can be considered only physiological, and never the cause of bladder dysfunction. Too many patients are still put off with this opinion, or still worse, subjected to abdominal surgery, only to find their bladder symptoms persist after operation.

States of the urine other than infection, as polyuria from immoderate fluid intake, and that of diabetes, should not be assigned etiological significance. While alkalis may relieve distressing frequency and dysuria, "acid urine" *per se* is never a causative factor.

Treatment

The vast majority of cases have infiltration and stricture as their basis and respond dramatically to simple dilatation with a sound. It is a common observation that the first instrumentation, usually a cystoscope, gives signal relief. To avoid recurrence, gradual, gentle, progressive intermittent dilatation should be carried out. Only after high dilatation—33 to 40° F in adults—is attained, is a reasonable permanency of cure assured. If the meatus seems tight below 30° F, meatotomy should be performed.

The granuloma type of caruncle will often extrude and be more amenable to treatment after several dilatations. If small in amount, it may be grasped with Allis forceps, its base transfixed, and coagulated at several points. Complete destruction is not necessary nor advisable. The surface will slough and small remaining points may be coagulated at a future sitting. Excessive scar tissue with ensuing contracture should be avoided. Thus large,

and especially annular growths, are better removed by sharp dissection, and the bleeding points coagulated after removal. Since this type of caruncle is a product of chronic inflammation, never be content with its removal without thorough treatment of the underlying chronic urethritis.

The telangiectatic variety springing from any point in the meatal circumference is essentially a benign new growth, and is seldom accompanied by urethral symptoms. Simple, thorough coagulation will suffice.

The papillary angioma shows potential or actual malignant arrangement of structure. After destruction by coagulation, the implantation of a seed or two of radium emanation insures against recurrence and may reduce the incidence of urethral carcinoma.

Acute urethro-trigonitis is best treated by the administration of alkalis and sedatives, and the injection through the urethra into the empty bladder of weak solutions of mild silver proteninate or neutral acriflavine. Except to obtain diagnostic specimens, the use of the catheter should be avoided, as should lavage, or irrigation of the bladder.

The importance of ruling out upper tract disease, especially tuberculosis and intrinsic disease of the bladder, should be borne in mind. When hematuria has occurred, the middle and upper urinary tracts must be carefully and fully eliminated as the source of the bleeding.

The irritation of atrophic vaginitis and trichomonas vaginalis infestation may simulate urethral pain and distress. These conditions should be recognized and eradicated. Cystometric studies will rule out the cord bladder.

A fair number of cases presenting one or more classical symptoms will not respond to the above measures. In these, polypoid, cystic, infiltrative or hyperplastic changes will be found in the upper third of the urethra, sphincter, and trigone. These will require the destruction of polyps and cysts by coagulation. Topical application of silver nitrate through an appropriate cystoscope will control granular hyperplastic urethritis. Occasionally the punch or resectoscope will be required to remove the obstructive tissue.

the urethra or bladder, varying from consciousness of these structures to severe pain. It is not related to nor relieved by voiding. This seems to distress the patient and produce secondary nervousness more than any other one symptom. Dysuria of some degree, from slight burning to severe terminal tenesmus, is usually present.

Urgency is commonly present. It varies in degree from slight inconvenience to near incontinence. It indicates involvement of the upper urethra, the trigone or the bladder.

Incontinence is usually due to defective musculature, but occasionally may be cured by the absorption of infiltration or fibrosis of the submucosa and the muscularis, or the destruction of hyperplastic or granulomatous tissue within the lumen of the urethra which interfere with closure.

Hematuria is usually terminal and accompanied by tenesmus. It occurs in acute urethro-trigonitis or acute exacerbation of chronic urethritis. Occasionally the telangiectatic caruncle will bleed. This occurs independent of urination, stains the clothing, and may be mistaken by the patient for bleeding from the vagina or rectum.

Difficult starting or propelling the urinary stream is not infrequent. Stricture or hyperplasia, or severe dislocation from cystocele, is usually present.

Referred pain is not uncommon and may be misleading. It is described as hypogastric, ureteral, vaginal, and to the groin, thighs, or lumbosacral region. It is truly astonishing to see some of these remote pains disappear with the correction of the urethral disease. While many patients with urethral disease have naturally unstable, nervous temperaments, the general nervous manifestations should be attributed to the annoyance and pain of the disease, rather than considered the cause of the urethral symptoms. Some cases have been driven to the verge of insanity by years of suffering from unrecognized or ill-treated urethral disease.

Diagnosis

Symptoms of bladder dysfunction should be sought in the history of every female patient, especially gynecological cases. Inspection of the fourchette should

note the presence of vaginal discharge and the appearance of the external urethral meatus.

Gentle expression of the contents of Bartholin's, the vestibular and Skene's glands will disclose purulent secretion if present for microscopic study. Varying degrees of cystocele should be observed, the cervix uteri inspected, and smears made for gonococci and trichomonas vaginalis if indications warrant. Atrophic vaginitis should be recognized and a bimanual pelvic palpation done, except where contraindicated.

The urethra should be palpated through the anterior vaginal wall—dense thickening, suburethral abscess, and diverticulae containing calculi, may be detected.

Stenosis of the meatus may be obvious. Extrusion of hyperplastic granular mucosa may be present or one of the varieties of caruncle observed.

A specimen of urine obtained by soft rubber catheter, negative chemically and microscopically, makes the diagnosis of urethral disease when characteristic symptoms are present. If the catheterized urine contains erythrocytes (nontraumatic), pus cells and bacteria, disease of the bladder and upper tract must be suspected. The diagnosis of urethritis can then be made only by ruling out the middle and upper tract by complete urological study. Having decided the urethra alone is responsible for the symptoms, it should be calibrated with the bougie a boule, and inspected by some form of cystoscope permitting a view of the entire circumference of the canal, sphincteric orifice, and trigone.

Bladder capacity should be estimated at this time. Many of the bladders accompanying long-standing chronic urethritis have lost their capacity as a result of frequent urination, or may be the seat of chronic systitis secondary to chronic pyelitis, chronic purulent urethritis, or chronic interstitial cystitis. While the correction of urethral disease will usually restore normal bladder capacity, some cases require hydrostatic dilatation before frequency will cease.

The urethroscopic findings belong in the realm of the urologist. It will suffice to say that redundant, granular mucosa may be observed in the anterior two-thirds, and in addition to this the posterior

ELECTRIC AUTOMATIC SERIALOGRAPH WITH CASSETTE HOLDER

MOSES EINHORN, M D, *New York City*

The serialograph, a device whereby several Roentgen exposures are obtainable on a single film, has been in use now for the past few years. The various types are more or less identical in construction, permitting from four to twelve exposures to be taken on a film. All of these serialographs necessitate shifting the cassette upon the completion of each exposure.

In a previous article,¹ I described a serialograph, which is also operated automatically, but the entire mechanism is built around a spring motor which enables a tray holding the cassette to revolve. The tray is attached to a metal disk with four notches, each corresponding to one-quarter of the circumference of the tray. A lever with a small projection at its outer end is held tightly to the side of the disk by a wire spring. An electromagnet is placed behind the lever, and upon pressing a button from a distance, the magnet is electrified, which in turn pulls the lever, enabling the tray to revolve. As soon as the button is released, the current is broken, the magnet demagnetized, and the lever is drawn toward the disk by the attached spring. While the disk rotates, the projection at the outer end of the lever follows its course in the opposite direction and upon reaching the first notch, causes the tray to stop rotating. In this manner, each time the button is pushed the cassette revolves one-quarter of its circumference and stops automatically.

Since then, the serialograph has been modified, so that the entire mechanism is now built around an electric motor, entirely eliminating the lever, the spring, and the magnet system. The new serialograph consists of two units: the cabinet and the control box. The cabinet is made of aluminum, the front of which is lined with lead, with the exception of a small square area, five by five inches, corresponding to the marked surface of the cabinet to permit the penetration of the rays (Fig 1). The top of the cabinet is fastened to a ball-bearing sliding arm, which is hooked to a cable, and regulated by a counter-weight.

The cassette, ten by twelve inches, is inserted through a small door provided on one side of the cabinet, (Fig 2), and held in position by a tray attached to the electric motor mechanism. Upon pressing a button at the control box placed at a distance from the cabinet, a current is made and the motor enables a tray, which contains the cassette, to rotate only a quarter of its circumference, bringing an unexposed quarter of the film directly beneath the marked area, and automatically breaking the current.

The apparatus is connected with a system of lights contained in the remote control box, which flashes a white light after the first three exposures, and a red light to indicate the completion of the fourth and final exposure.

The front part of the cabinet is constructed so that it may be used also as a

Discussion

DR GEORGE W STARK, Syracuse—Dr Hunner discussed the female urethra about 1910 According to the literature that is being published I would say that the modern urologist had rediscovered it about 1930

As to whether cystocele is a causative factor in infections in the female urethra, I wish to state that I have had many cases

of urethritis, where a cystocele was present, get well under treatment, and I have also seen many cystoceles operated without correcting the urethritis

I still feel that the real etiologic factor in infections in the female urethra is the napkin, massaging infectious matter from the vagina into the urethra

COLLEGE TO TRAIN MEDICAL SLEUTHS

Physicians are to be trained in scientific crime detection in the Department of Forensic Medicine of the New York University College of Medicine, we read in an announcement to the press Says Dean Wyckoff

"We found a widespread attitude of indifference toward the deficiencies of a system whereby politically appointed coroners with little medical training are authorized to pass on questions and problems which only a pathologist or a toxicologist can answer"

Remarking that as a whole forensic medicine is in worse state than was public health twenty-five years ago, Dean Wyckoff expressed the hope that after a broad program of education "a similar demand (as in public health) for men trained in legal medicine" would be created

"With a few local exceptions, the entire country depends for reports on suspicious and violent deaths on a system established

nearly 1,000 years ago and hardly changed since that time," Dean Wyckoff said

"In only a few places, such as New York City and Newark, is provision made for a scientifically trained medical officer to investigate all deaths by violence, sudden deaths and deaths under suspicious circumstances where crime may be suspected Yet the experience of these cities has been that one death out of every five falls into one of these classifications"

The new program will include discussions of the laws concerning medical examinations after sudden or violent deaths, the technic of examination, deaths from natural causes which become cases for the medical examiner, and medical jurisprudence This course will consist of twenty-five Saturday morning lectures and will be given by the entire staff of the forensic medicine department Photographs, x-rays, and other exhibits from the offices of the New York and Newark medical examiners will be used

NU SIGMA NU SMOKER

The Nu Sigma Nu Alumni Association of New York will have its annual smoker on Dec 4, at 8 P M., at the Phi Gamma Delta Club, 106 West 56 St, New York

City It is requested that all alumni who can attend notify the Secretary, Dr Norman E Titus, Room 2207, 730 Fifth Avenue, New York City

TREATMENT OF INFECTED WOUNDS WITH AZOCHLORAMID

LEON E. SUTTON, M.D. AND JOHN VAN DUYN, 2ND, M.D., *Syracuse*

*From the Department of Surgery, Syracuse University
College of Medicine and the University Hospital*

Azochloramid (N-N-Dichloroazodicarbonamidine) is a new chlorine antiseptic recently accepted by the Council on Pharmacy and Chemistry.¹ It has been shown to have strong antiseptic properties and greater stability in the presence of organic matter than other chlorine compounds used for bactericidal purposes.² The following study was undertaken with the hope of finding in azochloramid a more satisfactory chlorine antiseptic than those at present available.

The active treatment of infected wounds on many hospital wards consists mainly in applications of hot boric packs or irrigations with Dakin's solution. The boric packs are reasonably effective if the wound is not deep or pocketed and if little necrosis has occurred. If the wound is extensive and sloughing, the standard Carrel-Dakin technic is usually successful. This technic, however, is complicated, requires special equipment, and has been discontinued by many hospitals, although no satisfactory substitute has been found.

Most of the wounds seen in a general hospital lie somewhere between the small shallow and the extensive sloughing types. The treatment is usually either inadequate, laborious, or time consuming. An antiseptic that would combine the simplicity of boric applications with the efficacy of Dakin's technic would offer a more satisfactory treatment for the average infected wound. From a study of its properties, it seemed possible that azochloramid might be such an antiseptic.

Seventy-one infected wounds in a series of sixty-eight unselected cases were treated with azochloramid. Two preparations were used, azochloramid in triacetin and azochloramid in saline. Azochloramid in triacetin 1:500 is yellow in color, has a barely perceptible odor, and an oily consistency. Azochloramid in saline 1:3300 is clear and practically odorless. Azochloramid in triacetin was

used alone in sixty-one of the seventy-one wounds, azochloramid in saline alone in six, and both forms alternately in four.

The wounds are grouped under three main headings because of similarities in the respective methods of treatment (Table I). Under the first heading, superficial wounds, are included those which are wide-open and shallow such as granulating postoperative wounds, burns, etc. Under the second heading, deep open wounds, are included those which have penetrated at least the subcutaneous layer such as postoperative abdominal wound infections, incised abscesses, etc. The pockets and sinuses are considered under a third heading because of their small opening. Among these are the empyemas.

Method

The method of application was simplified as much as possible. The pockets and sinuses were merely injected with azochloramid in triacetin and their outlets covered with vaseline gauze. The deep open wounds were treated by packing the infected cavities with gauze saturated with the solution and also a covering with vaseline gauze. The superficial wounds were treated similarly by applying saturated gauze to the involved area and covering with either vaseline gauze, cellophane, or oiled paper. When azochloramid in saline was used, the solution was injected at regular intervals through rubber tubes fixed in the dressing.

The dressings were changed daily in all three groups except in two cases of extensive cellulitis. Because of pain in these cases, the dressings were left in place for longer periods and moistened at intervals with the azochloramid in triacetin. The duration of treatment in sixty-nine of the seventy-one wounds varied from two to twenty-six days with an average of eight. In two cases the dura-

Fig 2

Fig 3

cassette holder (Fig 3) Two small adjustable brackets can be released from the bottom of the cabinet, to support the cassette, while the top is held in place by a spring catch

A special wire marker in the form of a square five by five inches, with an attached handle, is used by the operator during fluoroscopy, to mark the skin of the patient, in order to indicate the exact area to be x-rayed

Advantages

- 1 Shifting the cassette is eliminated

- 2 The apparatus is automatically operated at a distance

- 3 The interval between each exposure is shortened

- 4 The serialograph can be used as a cassette holder

- 5 Due to the counterbalance, the entire cabinet can easily be raised and lowered

his health remains good, and his spirits excellent."—*Indian Paper*

thighs in which one thigh was treated with azochloramid in triacetin and the other by Dakin's technic. At the end of four days, the side treated with azochloramid showed beginning epithelization and a satisfactory granulating surface while the Dakin's treated side still showed no evidence of healing.

The other was a case of pneumococcus Type I lobar pneumonia with blood stream infection. The patient developed eight subcutaneous abscesses where clysis needles had been inserted in the thighs. The abscesses were opened and treated—three with azochloramid in triacetin, two by Dakin's technic, and three were merely covered with vaseline gauze. Within twenty-four hours, the abscesses treated with azochloramid were the cleanest and driest, the Dakin's next, and the controls last. Before treatment, cultures of all eight abscesses yielded pneumococcus Type I, five in pure culture and three mixed. After three days of treatment, cultures showed a decrease in pneumococci in all three of the azochloramid treated abscesses, no change in the two treated by Dakin's technic, and in the control group an increase in pneumococci in one and a decrease in the other two. Both of these last two, however, showed contamination.

In thirteen cases, azochloramid in triacetin and Dakin's technic were used alternately. The wounds treated by Dakin's technic were more prone to bleed, possibly because the necrotic tissue separated more completely. While there was apparently little or no solvent action on necrotic tissue by azochloramid, the granulations appeared relatively early with a tendency for the necrotic tissue to separate in a mass. (This tendency has also been noted by Kennedy³). Under treatment with Dakin's solution, however, the necrotic tissue readily dissolved and became friable.

Mild burning sensations upon application of azochloramid were noted in six cases. Azochloramid in triacetin was used in four of these and azochloramid in saline in two. In none was it necessary to discontinue treatment. Irritation about the wound was observed in five instances possibly due to inadequate protection of the skin with vaseline gauze. Two cases presented a somewhat generalized

dermatitis after prolonged use of azochloramid in triacetin on extensive areas. In both of these cases the dermatitis disappeared promptly upon discontinuing treatment, and in one reappeared when the azochloramid was reapplied.

In one case treatment was unusually prolonged. The patient, a girl of seventeen, developed a deep abdominal sinus postoperatively which was injected with azochloramid in triacetin one to three times daily for one hundred nineteen out of one hundred forty-six days. Temporary clinical improvement was noted after every series of injections though the sinus itself never closed the patient eventually dying.

Comment

The most satisfactory use for azochloramid in triacetin is in the treatment of infected subcutaneous pockets. The solution need merely be injected daily in most cases. Counter drainage is seldom necessary and healing is unusually rapid. In other postoperative wound infections, the results are equally satisfactory but infected cavities must be packed with gauze saturated with the antiseptic.

When injecting cavities and sinuses containing free pus with azochloramid in triacetin, it was noted that the pus floated off at the top leaving the heavier triacetin solution at the bottom. This may partially explain its unusual effectiveness in this type of wound.

In a certain number of cases a superficial film of necrosis appeared on the granulating surface after applications of azochloramid in triacetin. For this reason where skin grafting is contemplated it is better to use azochloramid in saline before grafting.

The ordinary principles of surgery must be observed with azochloramid as with other antiseptics. The infection should be well-localized, drainage complete, and the part immobilized if necessary. Azochloramid in triacetin, however, did appear to make counter drainage unnecessary in certain cases.

Azochloramid should be applied so that it comes into contact with every part of the infected wound surface.

The triacetin solution should be reapplied daily to keep it at full strength.

Sensations of burning may occur in

tion was one hundred thirty-three days in one and forty-two in the other

Observations

The effect of azochloramid in triacetin on purulent discharge was best observed in deep open cavities and subcutaneous pockets where the solution stayed in contact with all parts of the wound. The pus disappeared rapidly in nearly all instances. Where abscess cavities had been packed with gauze saturated with azo-

chloramid in triacetin, the interior was found clean and dry on removal of the gauze. The drying effect was so marked that a satisfactory loop of fluid for bacterial counts could no longer be obtained after one or two applications.

In a few instances the discharge did not diminish. Two were cases of chronic osteomyelitis. In a third the infection was not sufficiently well-localized and in a fourth the preliminary surgery was inadequate. In one case the purulent discharge increased while under treatment.

The saline solution of azochloramid was preferred to the triacetin in chronic empyema because it was considered less irritating. In each of three cases so treated, the discharge cleared up rapidly. In one of these, a bronchial fistula which developed during Dakin's irrigations closed subsequently during irrigations with azochloramid in saline. The saline solution was preferred also on wounds of the face such as extensive burns which were being prepared for skin grafting and where either Dakin's solution or azochloramid in triacetin would be too irritating.

The temperature was normal before and during treatment in forty-two of the sixty-eight cases. Of the remaining twenty-six, it was elevated throughout in fifteen because of some complication, in nine, the temperature fell to normal following drainage, and in two, the azochloramid itself appeared responsible for the fall in temperature. In one of these it rose after discontinuing treatment and fell again after treatment was resumed.

Table II shows the organisms present in sixty-six wounds on the first day of treatment. Bacteriological data were sufficient to show the results of treatment in fifty-two of the wounds. In thirty of these, there was a decrease in the numbers or types of bacteria, in eighteen there was no change, and in four an increase. Negative cultures were obtained in twelve wounds, in three of which they became positive again when treatment was discontinued. In ten of the mixed infections cultures became negative for one or more of the organisms during treatment. The remaining eight cultures showed a decrease in the number of organisms.

Table III shows the types of wounds in which treatment was classed as unsatisfactory from a bacteriological standpoint. It is probable that in most of these wounds the azochloramid did not come into contact with all parts of the infected area. This was apparently due to the type of the wound, incomplete drainage or inadequate technic.

In the treatment of fifteen cases azochloramid in triacetin and Dakin's technic were both used. Two cases deserve special notice because more than one lesion was present at the same time. One was a case of third degree burn of both

PYOPERITONEUM

CHARLES H. GOODRICH, M.D., F.A.C.S., Brooklyn

Pyoperitoneum is a label or index of conditions observed rather than a diagnosis. Today every diagnosis should include reference to the basic cause of conditions found. It is true that pyoperitoneum fulfills the dictionary definitions of "clinical diagnosis" even though we have made no differential diagnosis and no complete pathological diagnosis and still entertain more than one etiological concept as a tentative diagnosis. Thus far we have been unsuccessful in determining the basic lesion through diagnosis by exclusion. Cured of his acute disease this man remains an interesting scientific problem. Solution of this problem might help others.

Case Report

L. F., Italian, fifty-one, laborer, appeared at our office on May 21, 1935, ill for six months. At first there had been pain in the left hypochondrium, shifting after two months to the epigastrium. No pain for three months. This pain was most severe from 8 P.M. to 2 A.M. Legs swelled at first but had not for the past four months. Pyorrhea was severe four years ago but all teeth were extracted with a resultant improvement in health. Abdomen became swollen soon after beginning of his illness and medicines at first brought improvement. April 23, 1935, a subumbilical paracentesis evacuated three gallons of light brown fluid. The physician who did the paracentesis said his "liver was sick."

The patient had always smoked—pipe, cigars, and cigarettes—and alcohol was restricted to a little wine with meals. The micturition was six times during day, and twice at night. Bowels were usually somewhat constipated. There was marked general weakness. His normal weight was about 175 pounds—one year ago.

Examination: Pale, anxious facies, hollow cheeks, gaunt frame, weight 130 pounds. Hoarse voice. Moderate anemia. Slight icteroid tinge of sclera, no enlargement of glands of the neck. Thyroid negative. Diffuse leukoplakia of palate and tongue and inside of both cheeks.

The heart was in normal position, very slight hemic murmur at the apex, not transmitted. Lungs negative anteriorly, chest wall very thin, bones stand out boldly. Lungs negative posteriorly. Heart rate 100, Blood pressure 108/76.

A generalized collection of fluid was in abdominal cavity which fills the lower two thirds of cavity. There is a typical shifting dullness or flatness when patient turns on side. No masses are felt, there is no tenderness and no swelling of ankles.

Rectal: One external hemorrhoid. Lower four inches of rectum is clear and no tumefaction of any kind can be felt. Prostate is normal in size and not tender.

Patient was referred to the Methodist Episcopal hospital and admitted on May 27. The tentative diagnoses were: Malignancy of liver or cirrhosis of liver with ascites, generalized malignancy of the peritoneal cavity, tuberculous peritonitis, chronic nephritis with cardiovascular syndrome.

Temperature on admission was 100, pulse 90, blood pressure 100/50. Blood examination showed the red blood cell count 3,320,000, leukocytes, 10,600, hemoglobin, fifty-eight per cent, polys, seventy-two per cent, lymphocytes, twenty-eight per cent. Coagulation time was 3 minutes 20 seconds, bleeding time, 2 minutes 45 seconds, Wassermann and Kahn, both negative. The icteric index showed the blood to be badly hemolyzed. Van den Bergh, 0.3 mgm.

Blood chemistry: Urea nitrogen twenty-four, sugar, eighty-one, creatinine, 11, cholesterol, 119 mgm.

Urine showed faint trace of albumen, no sugar, large number of bacteria, few epithelial cells, ten-twelve white blood cells and a few granular casts.

Pulse rose gradually for four days and on the fourth day patient felt sicker and appeared weaker. There was increased sense of fullness in the abdomen and more ascites. A suprapubic paracentesis was therefore done after catheterization, and we were astonished to find thick, greenish yellow, malodorous pus flowing through the cannula into the pail. The amount collected was one gallon and one quart. Both following the examination in the office and

abrasions, superficial ulcers and burns, and where islands are left in third degree burns

Irritation of the skin about the wound edges may be prevented by the application of ointment or vaseline gauze

In the unusual event of a dermatitis which is more or less generalized, the azochloramid should be discontinued

Conclusions

Azochloramid, particularly azochloramid in triacetin, because of its efficacy, simplicity of application, and low toxicity, deserves a prominent place in the treat-

ment of infected wounds

Its greatest value appears to be in the treatment of postoperative infections. Proper drainage should be established and the solution made to come into contact with all parts of the infected area

Azochloramid compares favorably with Dakin's solution in most instances and the technic of application is much simpler

SCIENCE CALLED A "BLIND SAMSON"

An attack on science for its failure to solve the problem of human relations was made in a recent address by Dr Iago Galdston, executive secretary of the Medical Information Bureau of the New York Academy of Medicine, at the New York Museum of Science and Industry, 30 Rockefeller Plaza.

"I charge that science has dissipated, laid ruthless waste—if not maliciously, at least ignorantly—to the cultural and moral heritage of mankind, and left it spiritually bankrupt," Dr Galdston said. "I prognosticate, holding to my mind's eye that gazing globe, past history, wherein alone one can see the future pictured, that unless science amends its faults it will, like blind Samson, bring down the palace upon itself

to its own destruction and the irreparable disadvantage of humanity"

Dr Galdston said he was not attacking the material betterment that science had brought about, or the scientific method, but the "conceit" of those who looked upon science as the only key to life. He pointed out that it was science which had made the Four Horsemen of the Apocalypse virtual realities, by developing giant bombers capable of destruction of cities like New York, Berlin and London

"At rock bottom science is a moral, devoid of ethics and not concerned with the good, the true or the beautiful of Christ or Socrates," Dr Galdston said. "However, I look for science to become scientia and to develop a concern for man as a spiritual being"

PESTIFEROUS VIRUS DRAGGED FROM ITS LAIR

The invisible filterable viruses, rated among man's most dangerous enemies, which produce a wide range of disabling or fatal diseases such as the common cold, influenza, yellow fever and infantile paralysis, can at last be isolated in pure, concentrated form by means of a new powerful apparatus devised at the laboratories of the International Health Division of the Rockefeller Foundation

The obtaining for the first time of viruses in pure concentration will, it is expected, make possible more thorough investigations of their disease-producing properties which, in turn, may lead to better means for counteracting their deadly effects

The new virus separator, built on the principle of the cream separator, is described in detail in the *Journal of Experi-*

mental Medicine, official publication of the Rockefeller Institute for Medical Research, by Dr Johannes H Bauer and Dr Edward G Pickels. The journal is edited by Drs Simon Flexner, Peyton Rous and Herbert S Gasser

The virus separator is a highspeed centrifuge enclosed in a vacuum which whirls the virus-containing fluids taken from diseased animals and humans at the terrific speed of 30,000 revolutions per minute, representing a maximum centrifugal force in the fluid of 95,000 times gravity

This enormous force causes the invisible viruses suspended in the fluid to be deposited out in the form of a sediment, which, in animal experiments, has been found to be much more potent than the original fluid

½ oz in eggnog three times a day and digitals and strychnine in fairly full doses. Cascara was the only laxative used. Quinine, Basham's Mixture, and Zambelletti's Iron and Arsenic injections were given for several weeks. Full diet given after closure of fecal fistula.

Flat x-ray plates taken May 27 showed little beyond the fact that there was fluid in the abdominal cavity and a suspicion in the first flat plate of enlargement of the liver, not observed later. There were many hypertrophic arthritic changes in the vertebral column. The second film (June 24) was reported as "resolving ascites."

When the patient was discharged from the hospital his weight was 103. His wound was thereafter dressed weekly and was closed October 24. Very slow! Patient then weighed 144 pounds. He had a healthy appetite, went about as usual, and had not attempted to work. Bowels moved regularly without laxative. He has a fullness in the lower abdomen but no fluid wave can be elicited. There is no hernia. X-ray plates were taken of the chest and abdomen on October 21 with the following findings:

Abdomen No masses. No evidence of fluid. Especially marked hausturation of splenic flexure, significance? Essentially negative.

Chest No evidence of Koch infection. No pathological changes. Essentially negative.

In view of the rather astonishing recovery of this patient and the fact that there was accumulated so much pus in the general cavity of the peritoneum without gaseous distension, tenderness, masses, rigidity or the systemic evidences of acute sepsis, we cannot make a diagnosis of generalized pyogenic peritonitis. Malignancy and cirrhosis of the liver can be eliminated by laboratory findings and clinical course. The diagnosis narrows down to tuberculous peritonitis or serous ascites secondarily infected at the primary paracentesis one month before we saw this patient, or some suppurative lesion of the gastrointestinal tract, with generalized pus accumulation after rupture. The latter seems incredible because of the clinical history and the find-

ings at operation. Tuberculosis should be eliminated by the type and bacteriology of pus, the gross pathological anatomy observed at operations, and the prompt healing of the fecal fistula.

Dr Thomas B. Spence saw this case with me in consultation when the patient was at his worst and advised continuing the conservative surgical management which we had instituted. We believed that immediate radical operation searching for the basic cause of his trouble would undoubtedly have killed this man.

Semi-monthly or monthly observations of this patient have continued to date and he has constantly gained in weight and vigor. In November he began light work and since January he has done full work on fortunate days. His weight is now 172 pounds. He has had no symptoms of acute or chronic disease other than his glossal and buccal leukoplakia, which is much improved, and an incisional hernia.

Roentgenological examination on January 16 failed to reveal any abnormality in form or function of the gastrointestinal tract, except a barium filled appendix. He feels well, has no pain, gains weight constantly, and his essential functions work competently and amiably.

A complete accurate diagnosis remains unrecorded. When his hernia is repaired indications of the primary lesion may be exposed.

Addendum

On June 23, 1936, the ventral hernia was repaired. During the operation we discovered that this patient had had a tuberculous peritonitis, evidences of which were scattered over the summit of his bladder and the parietal peritoneum of the abdominal cavity. There were a few milary tubercles which were shriveled, over the cecum. The appendix was not easily brought to view and therefore left alone. He endured the operation and hospitalization very well and at this writing (August 1, 1936) seems to be in robust health.

280 PARK PLACE

Discussion

DR. HAROLD K. BELL, *Brooklyn*—This case report is very interesting and unusual. The Doctor deserves our congratulations on this patient's complete recovery accomplished by simple conservative surgical measures. Incision, drainage, and well-directed aftercare resulted in a cured patient. I quite agree that elaborate exploration at the primary operation might have

discovered the underlying pathology but would have abbreviated the report.

The ability of the peritoneum to take care of itself and the viscera which it surrounds and protects is appreciated today better than ever before and is well exemplified in this case. The bacteriological report showed almost a pure culture of a variety of micro-organisms. Either a

this simple operative procedure, the patient became exceedingly weak. Following paracentesis a chill supervened, then gradual improvement with receding pulse and temperature. Blood pressure was consistently low, 80/48 to 100/60.

The patient was treated conservatively for four days after paracentesis when it was determined best to make a conservative opening for drainage centered at the site of paracentesis. Leukocyte count was then 12,100, fifty-six per cent band forms. The account of the operation is as follows:

1 Under two per cent novocain local anesthesia, and after catheterization, a four inch low median abdominal incision was made just above the pubes.

2 When the thickened peritoneum was punctured, out flowed eight oz. of foul pus, some thin and some thick. A definite abscessed tract led the examining finger downward into the true pelvis. Pockets extended to the north, southeast, and to the southwest from the main section of this abscessed tract.

3 With the use of the suction, these communications were emptied as thoroughly as possible. A large soft tube was placed in the pelvis and a smaller soft tube was placed into the apparent communications of the cavity of the peritoneum. Suction drainage was established with the large tube.

4 Sutures closed the muscles and skin except where the tubes emerged. Chromic used in the muscle and linen to the skin.

Note The inflammatory process seemed to be that due to pyogenic organisms. Nothing in the tissues observed or the pus which was evacuated resembled tuberculous or hemorrhagic type of lesion, nor did there appear to be anything that suggested actual communication with the gastrointestinal tract.

The pathological report of the pus follows:

The specimen is thick, homogenous fluid of green color, and has a terrific odor, strongly fecal. A smear direct from the fluid shows it to be alive with organisms of all kinds, gram plus cocci and bacilli and gram minus cocci and bacilli. No pus cells are seen. Specimen seems to be almost pure culture of micro-organisms.

Culture and stained smears corroborated this view. No preponderant bacterium.

There followed a period of improvement and then a relapse distinguished by a lowering of the leukocyte count to 5,000 with forty-two per cent polys, fifty-eight per cent immature forms. R.b.c showed some achromia and some anisocytosis. At this time the hemoglobin was thirty-six per cent and red blood cells 1,940,000. Patient's resistance was reduced alarmingly. As drainage had ceased from our wound, it seemed wise to assume that the patient was not discharging

the pus which was re-forming and on June 26, under novocain anesthesia, the drain opening in the abdominal wall was enlarged and deepened by gentle blunt dissection. A large-sized soft tube was introduced into the pelvis and sewed in place.

On the third day after this procedure, patient began to have a discoloration of discharge which was suspicious. On the fourth day there was frank fecal discharge with much less pus. Tube was removed very shortly and several irrigations per day instituted and eleven days after its inception there was a complete closing of the fecal fistula. The patient, however, seemed more ill again and was developing a mass in the right lower quadrant. This gradually increased in tenderness and was incised under novocain July 16 through an oblique incision, the external oblique being split in the line of its fibers, pus being found just beneath and among the internal oblique fibers and the space beneath. The general cavity of the peritoneum seemed unopened. Six ounces of pus were evacuated. Two large soft rubber tubes were sewed in place. No sutures. Culture showed short gram negative bacilli, also a few very large gram positive bacilli.

By this time the patient was a pitiful collection of bones arranged in an orderly manner with wrinkled skin covering and a pallor that was alarming although the red blood cells were 2,770,000 and hemoglobin forty-seven per cent. His Schilling count showed forty-four per cent unfilemented forms of leukocytes with a total of only 6,200 and a polymorphonuclear count of fifty-six per cent. We had frequent leukocyte and Schilling counts and every variety of abnormal form of leukocytes were present in some degree. The staphs increased a little at this point and from this point on. There was a definite improvement on August 2, forty-two per cent filamented forms were present, polys sixty-one per cent, and staphs nineteen per cent.

On August 10, the hemoglobin showed a still further improvement (53%) and the Schilling count had improved. The patient's wound was beginning to look quite clean.

General management Ten days before third operation we let him out of bed and immediately thereafter he began to use the solarium daily. He ate reasonably well, bowels behaved remarkably well after the first two or three weeks. His morale was very excellent at all times especially after the third operation and he was entirely cooperative. Several supportive measures were used. Three Extralin capsules were given three times a day. Spiritus frumenti

JAUNDICE AND ANEMIA WITH RECOVERY IN SUCCESSIVE NEWBORN SIBLINGS

ROSE F. NETTER, M.D., *New York City*

We thought it interesting to add this group of cases to the literature because of the clear familial incidence of the syndrome of jaundice and anemia, associated with enlargement of the liver and spleen in the newborn, and because of the successful outcome following supportive measures, in the form of transfusions. So far, our cases have been followed for forty-four months, thirty months, and seven months respectively and no sequelæ or recurrences have occurred.

The previous obstetrical history of this mother was as follows:

In 1925 she gave birth to a normal, full term infant who died, at the age of one year of pneumonia, following measles. In 1926 she was delivered (breech extraction) of a normal male child now living and well. In 1928 she gave birth to another child who became jaundiced on the second, and died on the third day. The liver and spleen were enlarged. In 1930 she gave birth to an infant who survived only ten hours. There was no jaundice or hepatosplenomegaly. In 1931 the mother suffered a spontaneous abortion at three months. The cause was undetermined.

Her subsequent babies have been delivered at the New York Infirmary for Women and Children. These we have been able to see at an early stage through the courtesy of the Obstetric Department, whom we wish to thank for their cooperation.

On July 21, 1932 this mother, then twenty-eight years old, was delivered of a jaundiced baby boy weighing six pounds, seven ounces. The mother's Wassermann was negative, and her blood count was normal—4,600,000 r.b.c. with eighty per cent hb, 6500 w.b.c., sixty-six per cent polys, and 34 per cent lymphs. The baby's blood count was r.b.c. 2,500,000, hb fifty-three per cent, w.b.c. 13,700, polys sixty-seven per cent, lymphs twenty-three per cent, eosinophiles three per cent, basophiles two per cent, transitionals five per cent. Anisocytosis, basophilia, and achromasia were present. There were many normoblasts, microblasts, and megaloblasts. The coagulation time was four minutes. The reticulocyte count was fifty per cent. Thirty-

five c.c. of blood and 100 c.c. of saline were given subcutaneously. The next day 125 c.c. more of saline were injected.

There was a difference of opinion as to the size of the liver and spleen, and x-ray showed that the liver was not enlarged.

On the sixth day the hemoglobin had fallen to 35 per cent, the r.b.c. were 2,400,000, the total and differential white count were about as before. There was a trace of bile in the urine. Liver and spleen were enlarged. A transfusion of 100 c.c. was given. Two days later, the hemoglobin had risen to fifty-eight per cent, and the next day it was seventy-eight per cent. Reticulocytes were now 65 per cent. Platelets were normal, the bleeding time was two minutes. There was general improvement and a decrease in the size of the liver and spleen.

On August 2, six days following the first transfusion, another one of 120 c.c. was given. The next day the icteric index was still 55.5, the Van den Bergh was delayed direct. On August 5, the hb had risen to ninety per cent although the red count was still only 2,780,000. When the infant was taken home against advice, on the twentieth day, its general condition was good, the jaundice had decreased, the liver and spleen were three and two cm. respectively, below the costal margin.

The child was readmitted September 14, 1933, at the age of fourteen months, for an upper respiratory infection. Its temperature on admission was 102.4° F. A blood count the day after admission, when the temperature was normal, was r.b.c. 5,030,000, hb seventy per cent, w.b.c. 7,600, polys forty-one per cent, lymphs fifty-seven per cent, and transitionals two per cent. Liver and spleen were not palpable. The child was subsequently seen in the clinic on April 30, 1934 (age, 1 year 9 months), February 19, 1935, (age, 2 years 7 months), and April 5 (age 2 years 9 months) each time for an upper respiratory infection. The child was seen for follow-up on October 18, 1935 (age 3 years 3 months) and again on March 12, 1936 (age 3 years 8 months). On none of these occasions was the spleen or liver palpable. The color was good and the child did not appear chronically ill. The mother would not permit a blood count to be done.

well-developed immunity or attenuated strains of bacteria, or both, must have been active factors in this man's reaction to his infection and to his ultimate recovery. There was more or less complete absence of signs and symptoms of localized intra-abdominal inflammation or the recognized systemic reaction to acute sepsis. The accumulation of pus in the intercommunicating pockets disclosed at the primary operation leads one to conclude that this patient developed multiple abscesses rather than generalized pyogenic peritonitis as such. The patient's defensive mechanism is

manifested by his localization of the abscess in the abdominal wall and also in the complete closure of his fecal fistula in eleven days. Subsequent x-rays visualized the appendix and proved that it had not sloughed off as the result of acute inflammation. Nevertheless a small slow gastrointestinal perforation of some nature would seem to be a logical guess as to the underlying etiology, whether it resulted from organic intestinal pathology or from perforation at the time of his original paracentesis, we do not know.

ENLISTING THE CHURCHES IN THE CANCER CRUSADE

It has been discovered by the New York State Branch of the American Society for the Control of Cancer that church groups offer a splendid field for education in cancer control. At the present time a concentrated effort is being made to educate the people of Erie and Monroe counties in this way, and the work is reported quite successful. Audiences range from a dozen to hundreds. It all began when a Protestant church "brotherhood" found itself without a speaker for a dinner meeting, and appealed to the State Branch. One was provided, and he aroused such interest that more talks were requested, and four have been given, two for men, one for women, and one for a mixed group. Next a Holy Name Society became interested, and several talks were given.

As related by Dr Louis C Kress, in a paper read before the directors of the ASCC, it was then decided to call upon the clergymen, and they reacted favorably. The plan for meetings was outlined and the pastor appointed a committee to make a house-to-house canvass in that community, inviting not only the members of the church, but every adult regardless of religion. Several good meetings were arranged in this way. Many of the Church groups have newspaper affiliations and notices of the cancer talks appear for days and weeks in advance.

Last Fall at a meeting of clergymen, one of the younger men, who is in sympathy with lay cancer education, proposed that the clergymen at the meeting allow and arrange for cancer talks to be given at the meetings of their respective church groups. A few of the older men scoffed at the idea and said that it was absurd, but several of the younger men thought well of the idea and offered their co-operation. Now instead of

going to those clergymen and requesting dates for talks, invitations are received from them and many talks have been arranged in this way during the past year.

The policy that has been adopted and is being carried out is to go out and sell the talks to interested groups and to ask for the opportunity to present the cancer problem before their respective groups. The results to date have been gratifying in that at the present time there are from two to five lay talks—to church groups, civic groups and students—given each week.

The material presented at the lay meetings is suited to the groups. The type of talk is determined by the type of audience and by the manner in which the information is received. An endeavor is made to keep on a level with the intelligence of the group and a guide to that is usually obtained from the person who arranges for the talk. The merits of an illustrated talk are obvious, and whenever it is possible to do so, lanterns and screens are used.

In all of the talks are emphasized the general facts concerning cancer, such as—cancer is curable, preventable, not inherited, not contagious or infectious, not a blood disease and not a loathsome disease. The people are encouraged to talk about cancer and especially to broadcast the cures, the failures are usually advertised. The general symptoms of cancer are pointed out, their significance is explained and the people are told what course of procedure to follow when in doubt. They are told that people who are suspicious of their condition should be encouraged to go to their family physician to seek aid and that he in turn will send them to an organized tumor clinic if he sees fit. At the end of the talk, questions are answered and cancer literature is distributed.

Discussion

We see in these cases the salient features of erythroblastic anemia¹ of the newborn. They are

1 Jaundice—which may reach serious proportions, as in icterus gravis neonatorum.
2 Anemia—consisting of low r.b.c. and hemoglobin count, and the presence of many immature forms

3 Enlargement of the liver and spleen

4 Onset at birth or within a few days

5 Familial incidence.

6 Absence of lues or other infection

7 In some cases there is also present a generalized edema of greater or lesser severity

The whole picture is based on a persistence of the fetal state of the hematopoietic system. The first blood formation²⁻⁴ takes place in the blood islands of the yolk sac where the mesenchymal cells become the primitive blood cells. These are differentiated into hemocytoblasts or stem cells from which, after they have migrated into the fetus, develop all subsequent red blood cells. The stem cells are deposited and proliferate in the various organs of the fetus which successively serve as the blood forming centers, namely, the liver, spleen, and bone marrow.

Normally the bone marrow persists as the chief blood-forming organ² after birth. In contrast to this, postmortem examinations on cases of erythroblastosis have shown the liver and spleen replete with active hematopoietic centers⁵⁻⁸—a persistence of the fetal state.

In fetal life the blood contains many immature forms, which in the normal baby practically disappear during the first week after birth⁹. In erythroblastosis, however, they persist in association with a marked anemia¹⁰. Whether the persistence of the blood-forming centers and the presence of a large number of immature cells are a response to the marked anemia, or whether the anemia is a result of the failure of the red blood cells to reach maturity is not known. Is the anemia on the other hand due to an excessive destruction of red blood cells, a theory to which the presence of jaundice lends support, or is the jaundice due to the large number of immature cells in the liver which compress and so obstruct the bile capillaries?

This is the basic pathologic picture, which with different symptoms predominating leads to the division into three groups,¹⁰⁻¹¹ namely—(1) erythroblastic anemia of the newborn as here described, (2) icterus gravis neonatorum^{8,12,13} in which the jaundice is predominant, and (3) universal edema of the newborn, with more or less intense edema as the conspicuous symptom^{8,14}.

The underlying cause of the condition is still being sought. The familial incidence,¹⁰ which is so strikingly brought out in this group, suggests consideration of the following

1 Hereditary factors, i.e., changes innate in the chromosomes. This is demonstrated in the cases quoted by Abt.¹¹

Hilgenberg reports a mother who had several normal children by her first marriage and gave birth to six infants who died of icterus gravis neonatorum by her second marriage. On the other hand, E. V. Gierke reports the case of a father who had a normal daughter by his first marriage and by his second wife two newborn infants who succumbed shortly after birth and were found at autopsy to have suffered with icterus gravis neonatorum.

2 Congenital factors, e.g., conditions in the mother, for instance anemia, toxemia or infection, none of which has been found definitely to be the cause. None of these was present in the mother of our cases, or in the carefully controlled cases reported by Smyth.¹¹

An Australian mother had previously given birth to nine infants, the first two children were normal and survived, there was one stillborn premature birth and 6 infants had developed icterus gravis neonatorum and died from 3 to 11 days after birth. A prophylactic attempt to prevent icterus gravis for the infant of the tenth pregnancy consisted of hospitalization of the mother through the entire course of her pregnancy, with extremely careful supervision and regulation of her diet. The mother was perfectly normal during her time of pregnancy. Seven days before labor was due a Caesarian section was performed and a normal female infant was delivered. The mother's tubes were resected and tied. The infant remained normal for twenty-four hours, when it became drowsy and progressively icteric and died 70 hours after birth.

The course and prognosis seem to depend mainly on the initial severity of the condition. Those that recover usually do so in two or three weeks.¹⁰⁻¹¹ There is usually no response to liver or iron therapy. Transfusions although not always successful are the method of choice.

On August 8, 1933 the mother again presented herself at the prenatal clinic. Her hemoglobin was seventy-five per cent and Wassermann negative. She seemed perfectly well. On September 22 she was delivered of a baby girl, who appeared perfectly healthy at birth. The color was good, but slight jaundice developed on the third day. The liver and spleen were palpable. The general condition was good. In view of the familial incidence, it was deemed advisable to discontinue the breast to preclude a maternal source as the etiological factor. The condition continued in spite of this. The blood count was r b c 2,180,000, hb fifty-six per cent, w b c 19,800. There were anisocytosis, poikilocytosis, stippling, and polychromatophilia. The bleeding time was five minutes and the clotting time four minutes. There were immature forms (3 per cent). There was no significant change in the blood count by the thirteenth day, when the child was taken home against advice. At this time the spleen was about three cm below the costal margin. The general condition was good.

The child was readmitted on October 26, at the age of five weeks, with a history of jaundice, but none was apparent on admission. The mother also stated that the stools had been white for one day. The baby passed one white stool of normal consistency on the evening of admission, but all subsequent movements were colored. Unfortunately the white stool was not subjected to laboratory examination, but there was no jaundice and the urine contained no bile or urobilin at this time.

The blood count was r b c 2,810,000, hb forty per cent, w b c 9,900, polys forty-nine per cent, lymphos forty-nine per cent, eosinophiles two per cent. The liver was two cm and the spleen three cm below the costal margin. Wassermann was negative. One week later (Nov 2) a transfusion of 100 c c was given. The following day the blood count rose to r b c 5,300,000, and hb sixty per cent. Following a slight initial drop, a few days after the transfusion, the blood count became steady, and when the baby was discharged on November 21, four weeks after readmission, it was r b c 4,610,000, hb sixty-three per cent, w b c 9,100, polys fifty-eight per cent, lymphos forty per cent, eosinophiles two per cent. There were still slight anisocytosis and very slight chromatophilia.

On February 28, 1934 the child was brought to clinic for check-up. It was then five months old. The blood count was hemoglobin seventy-seven per cent, r b c 4,640,000, showing slight anisocytosis and central pallor. On October 23, (13 months) another

check-up showed seventy-eight per cent hemoglobin, 4,530,000 r b c, normal in appearance. The child was seen on February 19, 1935 (17 months) for an upper respiratory infection. On October 18, (2 years 1 month) and again on March 12, 1936 (2 years 6 months) it was seen for follow-up. The mother would not permit another blood count. The color was good. The spleen was not felt.

A third case is G M, born August 11, 1935. Jaundice developed the following day. The blood count was r b c 4,010,000, hb 126 per cent, w b c 22,600, polys seventy-one per cent, lymphos twenty per cent. There were nine premyelocytes, and chromatophilia, aniso- and poikilocytosis. The platelets were 448,600. The bleeding time was one minute, coagulation time one minute. The liver was five cm below the costal margin and the spleen was enlarged. The child was put on iron, calcium, and viosterol. In view of these findings together with the family history, a transfusion of forty c c was given in an attempt to ward off the profound anemia seen in the preceding infants. Nevertheless, daily blood counts showed that the red and hemoglobin counts were falling progressively. On August 17, six days after birth, they were r b c 2,530,000, hb seventy per cent, w b c 12,100, fifty-two per cent polys, thirty-nine per cent lymphos, three per cent monos, two per cent eosinophiles, four premyelocytes. There were slight aniso- and poikilocytosis and slight chromatophilia. A transfusion of fifty-five c.c. was given. (The iron was discontinued). The following day, the red cell count was 3,410,000 with seventy-five per cent hb. On August 20, the hb had reached eighty-nine per cent, but for the next ten days there was a progressive drop to forty-five per cent hb and 1,890,000 r b c. A transfusion of seventy-five c c brought the r b c back to 3,030,000 and the hb to sixty-eight per cent. After this it held its own fairly well until the baby was taken home against advice on September 20, forty days after birth. It had had no jaundice since the tenth day. Two days before discharge the icteric index was 3.4. The fragility test was, Patient 0.46 to 0.38, control 0.46 to 0.40.

A month later the child was seen in the clinic. The liver and spleen were not felt. Color was good. The blood count was r b c 4,670,000, hb eighty per cent, w b c 18,500, polys twenty-eight per cent, lymphos sixty-eight per cent, monos, one per cent, eosinophiles three per cent. The red cells appeared normal. The baby had gained three pounds. On March 12, at the age of seven months, the child appeared perfectly healthy.

NEPHRITIC SYNDROMES CAUSED BY INDUSTRIAL POISONING WITH CARBON TETRACHLORIDE

SAVERIO FRANCO, M D , *Brooklyn*

The mention of nephritic conditions caused by carbon tetrachloride poisoning is rare. The texts on toxicology make no definite mention of the renal manifestations of carbon tetrachloride poisoning and confine themselves to the description of symptoms arising from involvement of the central nervous system, lungs, the gastrointestinal tract, and liver. But very few cases have been reported stressing the renal involvement and these have been due to the inhalation of carbon tetrachloride fumes. Our interest in the subject was aroused by two cases of carbon tetrachloride poisoning following the inhalation of fumes from industrial cleaning fluids. One case presented a picture of chemical uremia as is seen in the necrotizing nephrosis of bichloride of mercury poisoning. The other case was more in the nature of an acute nephritis.

Technically, carbon tetrachloride is a colorless, transparent liquid very much like chloroform. It is said to be more toxic than chloroform. It is insoluble in water but is miscible with benzene, alcohol, and chloroform. It is soluble in all fixed and volatile oils. It is volatile at ordinary temperatures. It is noninflammable and thus favors its use in industry where it is used as a solvent for fats and gums, as a dry cleaner, to remove ink from stencils, to clean oil from machinery, and it is used also in fire extinguishers. In medicine it has been in use as a vermifuge in hookworm disease since 1921.

Reports of its toxicity have always accompanied its use. It was said to have been used about 1860 in the treatment of headache, neuralgia, and chorea. It produced ill effects by inhalation and fell into disuse. At the beginning of this century, two cases were reported of poisoning from carbon tetrachloride following shampoos with fluid containing this chemical. One, in the *Lancet*,² (1907) described the case of a woman who fainted during such a shampoo and was ill for

a day with headache and nausea but recovered. The other, in the *J.A.M.A.*,³ (1909) described a fatality from a similar procedure. In 1920, there was a short description⁴ of a case of a young girl who had vomiting and headache after painting golfball molds with a paint containing carbon tetrachloride. After the introduction of carbon tetrachloride as a vermifuge by Hall,⁵ in 1921, there appeared reports of toxic symptoms and even death in certain individuals especially if they were cachectic or alcoholic. Nearly all these suffered from acute gastroenteritis and toxic hepatitis with jaundice. The pathological reports stressed the typical central necrosis of the liver. There were also hemorrhagic areas in the gastrointestinal tract. Phelps and Hu⁶ described suprarenal necrosis which was not confirmed by others. These reports barely mentioned renal involvement. It is interesting to note that of the ten cases described by Lamson, Minot, and Robbins in 1928,⁷ three developed anuria.

Its use in fire extinguishers was reported to have caused poisoning either from the carbon tetrachloride itself⁸ or from the poisonous gases⁹ formed when these fire extinguishers were used in a closed room and high temperatures as would occur in a fire. The industrial use of carbon tetrachloride has given rise to poisoning by contact and by inhalation. Dermatitis has been caused by direct contact of the hands with cleaning fluids containing carbon tetrachloride. Acute poisoning has resulted from the inhalation of carbon tetrachloride fumes. The fluid vaporizes at room temperature and the vapors of carbon tetrachloride are heavier than air.¹⁰ This favors the retention of the fumes in the lower part of work rooms. At room temperature each cubic centimeter of carbon tetrachloride when evaporated yields 257 c.c. of carbon tetrachloride vapor, and 5,000 parts of the vapor per 1,000,000 of air is considered the maximum that may be tolerated even for short periods without

and seem to be mainly supportive¹⁵ Milder cases recover without treatment in two or three weeks. Severe cases are often fatal in spite of transfusions and other supportive measures.

Summary and Conclusions

1 Four cases of jaundice with anemia in successive newborn siblings are presented.

2 The etiologic factors are discussed. In the cases reviewed in the literature, as well as in those presented here, the etiology is still obscure.

3 The value of transfusion is studied. Some moderately severe cases recover with repeated transfusions. The three treated cases presented have recovered, without sequelae or recurrences to date.

TACKLING SILICOSIS AT ITS SOURCE

Manufacturers who make claims for the efficiency of their dust-control machinery in preventing silicosis are to be given a chance to prove them. The State Department of Labor has established a "field laboratory" in a granite quarry at Letchworth Village in Rockland County. The granite where the tests are to be made is of high silica content and the dust to be created by drilling this rock will show a high percentage of free silica, the most injurious of all dusts when inhaled. Each applicant must furnish and install at the testing field the drills, compressor, piping, and other essential equipment and also furnish the drill operators, compressor engineer, and all other workmen required to operate the drilling equipment and dust control equipment during the test period. The Labor Department will furnish testing engineers and assistants to conduct the test, make the necessary measurements and furnish all testing instruments.

A dispatch from Washington says that development of a mask affording "complete protection" against silicosis, often acquired by workmen engaged in sand-blasting and such work, is announced by the Navy Department. The mask was designed by W. P. Biggs, departmental safety engineer,

and has been tested for several months in navy industrial establishments.

In the Navy Department the mask is used in shot and sandblasting rooms, where there is a heavy concentration of fine dust. There are several masks commercially distributed, but Mr. Biggs said he found them to be of only "semi-protection."

Its development is the result of several years of research by navy experts, Mr. Biggs explained. The interest of officials was aroused when they discovered that seventy-five out of every hundred men applying for work as sandblasters already had silicosis in varying stages of development.

Since the present mask has been developed only men who are in perfect physical condition are engaged. They are submitted to a physical examination every thirty days, and are taken off of the work at any sign of obstruction in the respiratory tract and are put at other jobs.

A new glass also has been worked out by the navy's safety experts which removes one hundred per cent of the ultra-violet rays and seventy-eight to ninety-eight per cent of the infra-red rays, which are injurious to the eyes. It is used in goggles by men engaged in welding and similar work involving the use of brilliant lights.

Dr. W. C. Templer, general surgeon of the Corning Glass Works at Corning, was elected president of the New York State Society of Industrial Medicine at its an-

nual convention in Schenectady on Nov. 5. Dr. J. D. Kaliski, of the workmen's compensation committee of the state Medical Society, was the principal speaker.

November 17 the urine was negative. By November 20 the blood chemistry was normal, icteric index, nine. All tests of renal function were normal.

The important laboratory findings are reported in Table I.

The clinical picture in this case was identical with that of a necrotizing nephrosis due to bichloride of mercury poisoning. In fact, mercury was looked for in the urine and stools, but was absent. We were very much surprised that carbon tetrachloride could cause such a condition and we were engaged in searching the literature when the second case was admitted.

CASE 2 N P, Italian, street cleaner, age forty-nine, married, was admitted to the Long Island College Hospital November 27, 1933, complaining of vomiting, diarrhea, abdominal cramps, and cough with bloody expectoration for ten days. Three days prior to admission he developed shortness of breath. The family history was irrelevant and his past history showed that he had always been in good health. He drank heavily, at least a quart of wine a day for years. His present complaint began November 17 when he was assigned to cleaning stencils. This work was done in rather close quarters indoors and with several other men he cleaned the ink off stencils with a commercial fluid called "Blankrola" (After admission we investigated this fluid and found that it contained carbon tetrachloride in addition to a normal cleaning solvent.) That night he had a headache and dizziness. The next day nausea, vomiting, diarrhea, abdominal cramps, and cough with bloody expectoration developed. These persisted up to the time of admission. Three days prior to admission he became short of breath and was compelled to stay in bed. He had several nose bleeds prior to admission, and did not complain of oliguria at any time.

Physical examination on admission showed a large individual in respiratory distress with definite cyanosis. His nose bled during the

examination. Blood pressure was 180/100. The pupils were regular and reacted to light and the fundi were negative. There was no icterus of the sclerae. The lungs showed subcrepitant râles at both bases. The left border of the heart was in the midclavicular line, fifth intercostal space. The sounds were forceful, the rhythm regular, and there were no murmurs. The abdomen was tense and distended. There was dulness in the flanks but no fluid wave could be elicited. The liver was not definitely felt but liver dulness was percussed three fingers below the costal margin and this area was tender. There was mild sacral edema but no shin edema.

The urine had a specific gravity of 1.010, a trace of albumin, and many red blood cells. Two or three casts per high power field were found. The blood chemistry showed a nitrogen retention. Icteric index was twelve. Hemoglobin was eighty per cent, red cells 4,200,000, white cells 8,000.

Fluids were forced, intravenous glucose and saline were administered. Calcium was given as calcium gluconate $z i t i d$ by mouth and ampule 1 (grs \times) $b i d$ intravenously. Colonic irrigation was given daily and heat was applied continuously to the kidney regions. Vomiting subsided in two days. The urinary output was never below 1,500 c.c. during this critical period. In three days the blood pressure was 160/100, and remained at that level during the remainder of his hospital stay. The cyanosis and pulmonary congestion disappeared in a few days. The abdomen became softer, but the liver remained below the costal margin. The sacral edema disappeared. The urine continued to show a trace of albumin. The sediment at various times during the month of December showed red cells and casts despite the fact that the chemistry reached normal on December 19. The specific gravity of the urine had on several occasions reached 1.022. The important laboratory findings are reported in Table II.

The clinical picture in this case has been that of an acute nephritis. We can-

TABLE II

Blood Chemistry	Nov 28	Dec. 1	Dec. 4	Dec. 9	Dec. 11	Dec. 15	Dec. 19

ill effects. The acute poisoning from inhalation of carbon tetrachloride is usually manifested by burning of eyes and throat. This is followed by headache and dizziness in a short time. Within the next twenty-four hours epigastric burning, vomiting, and diarrhea set in. Irritation of the lungs gives rise to an acute bronchitis. In mild cases these symptoms may clear up shortly. But in severe cases the gastrointestinal symptoms get worse, the patient becomes jaundiced and lapses into coma. Some few cases develop oliguria and edema. Most of the cases reported have shown dominant manifestations along the gastrointestinal tract, pulmonary tract, and central nervous system. There have been but seven case reports where the renal involvement has been dominant.

We wish to add our two cases to this group.

CASE 1 J M, age thirty, Puerto Rican, entered the Long Island College Hospital November 1, 1933, with a complaint of abdominal cramps, nausea, and vomiting of three days' duration. The family history was negative. The past history revealed that his health was always good, he was married and his wife was in good health. There was no history of venereal disease. He drank and smoked but little. He worked for a steamship line doing odd work about the vessels when they docked. On October 30, he had been assigned to cleaning condensers in a small space on a newly arrived boat. He worked two hours with a cleaning fluid which was routinely used for such purposes. This was the first time that he had worked with it. (We endeavored to find out the nature of the fluid, but the patient was so sick that he was unable to give us this. It was only several weeks after admission that we ascertained that it was carbon tetrachloride cleaning fluid. This information was obtained from the company which employed him.) After he had been working for two

hours he developed a headache, became nauseated, and vomited. He was sent home and the vomiting persisted. Abdominal cramps developed and he was sent to the hospital.

On admission his T P R. was normal. The blood pressure was 120/70. The patient vomited when he attempted to drink anything. The pupils were equal, but somewhat irregular, they reacted to light. He had an icteric tint to the sclera. The lungs were clear, the heart was not enlarged and the sounds were forceful and regular. The abdomen was tight in the upper quadrants and there was some tenderness over the liver area. No edema was present. Knee jerks were active and equal.

On November 2, the following laboratory data were reported:

Urine Specific gravity 1.026, trace of albumin, occasional granular cast, no red blood cells. Blood chemistry revealed nitrogen retention. Blood count showed hemoglobin eighty per cent, white cells 13,400. Icteric index was thirty. Blood Wassermann was negative.

The vomiting continued despite gastric lavage, intravenous saline, and glucose. His urinary output diminished despite a fluid intake of approximately 3,000 to 4,000 c.c. November 5, he passed four ounces of urine, November 6 eight ounces, November 7 eight ounces, and November 8 there was total anuria. The intravenous medication was continued, hot colonic irrigations were given every eight hours, and continuous heat to the kidney regions. The urine on November 7 had a specific gravity of 1.019, there was a faint trace of albumin and no casts. Puffiness of the face was apparent. Coarse rales were heard. Tenderness over the liver persisted. The patient was very drowsy. The blood pressure continued at 120/80. Blood chemistry November 8 and 9 showed increasing nitrogen retention and acidosis. On November 9 blood pressure was 140/80. The patient voided twenty ounces, and thereafter the daily output increased to 156 ounces on November 12. The patient improved rapidly. November 14 the blood pressure was 120/80.

own cases two syndromes can occur. One is that of acute nephritis with red blood cells, casts, and albumin in the urine associated with nitrogen retention and elevation of blood pressure. The other syndrome is more akin to the necrotizing nephrosis such as occurs in bichloride poisoning where the urinary sediment is quite negative, or does not show more than albumin and casts, while there is nitrogen retention. The blood pressure may or may not be elevated.

As to what does happen in the kidneys, it is hard to say anything too definite because of the scarcity of the pathological reports on these kidneys in the human being and the wide variation in opinion as regards experimental findings. Phelps and Hu⁶ in describing the kidneys in their two cases that died after carbon tetrachloride had been administered by mouth as an anthelmintic said that the kidneys were congested. In one of the patients, a child, the capsules showed a few petechial hemorrhages. Microscopically "in the kidney, some of the tubules and the capsular spaces of the glomeruli were distended with bluish or pinkish granules, probably precipitated albuminous material." MacMahon and Weiss¹⁸ describe the case of a man thirty-four years old who drank one ounce of carbon tetrachloride in milk. He was an alcoholic and died in forty-eight hours. He was jaundiced. The liver edge was two fingers below the costal margin. The abdomen was distended and a fluid wave was present. The urine showed a trace of albumin. The NPN was 115 mgs. The outstanding finding was that the total blood volume obtained from the pulmonary artery contained sixty-four per cent fat and that from the upper end of the inferior vena cava contained twenty-five per cent fat. The lungs were edematous and congested. The liver was large and greasy and showed the usual central necrosis. The kidneys weighed 400 gms. They were enlarged, quite firm, and had a smooth, yellowish, red surface. On section the cortex was thickened, yellow, and opaque. The pyramids were clearly defined and congested. Microscopically both the glomerular capsules and tubules contained precipitated albumin. In addition, the tubules contained homogeneous and coarsely granular eosin staining casts

and a few desquamated epithelial cells. When stained for fat, small fat cylinders were visible within the glomerular capillaries and fatty casts were present in the collecting tubules. The cells lining both the convoluted and collecting tubules were filled with small fat droplets. The background for this may have been the fatty alcoholic liver from which fat may have entered the circulation when central necrosis took place in the liver. The fat in these organs which are supplied by the left side of the heart must have gotten through the pulmonary circulation or precipitated from the blood.

Meyer and Pessoa¹⁹ in 1923 described lesions in the kidneys of dogs that had received toxic doses of carbon tetrachloride by mouth. The external surface of the kidneys was not markedly abnormal but microscopically there were many fat droplets in the protoplasm of the epithelial cells of the convoluted tubules and of the loops of Henle. These fat droplets occupied that portion of the cell nearest the lumen and compressed the nucleus against the stroma side. In a few cases there was a small amount of congestion of the glomeruli. In several control animals that did not receive carbon tetrachloride there were only a few fat globules in the renal parenchyma. Meyer and Pessoa stated that the kidney lesions cleared up just as did the central necrosis of the liver. The next year Schultz and Marx²⁰ carried out experiments showing that the amount of stainable lipoids was the same in control dogs as in those receiving carbon tetrachloride and they concluded that definite fatty changes were not produced in the kidneys by carbon tetrachloride.

Gardner²¹ and the Johns Hopkins group in 1925, following the oral administration of carbon tetrachloride in varying doses to dogs, found that evidences of real nephritis appeared no more frequently than would be found in any large series of dogs. Examination of their protocols shows that in dogs killed by massive doses of carbon tetrachloride there was an accumulation of albuminous material around some of the glomerular tufts within Bowman's capsule. Moderate cloudy swelling of the tubular epithelium was present, but no fatty change or necrosis of these cells was found. Two dogs

not say at this time what the previous renal status was in this man or whether he had a previous hypertension but his nephritis has improved and our tests do show good renal function

The first mentioned case of nephritis following carbon tetrachloride poisoning was by Boveri in 1929¹¹ He described the case of a young man twenty-seven years old who worked in a factory using carbon tetrachloride to remove grease from clothes After an exposure for two days in a small chamber the patient developed malaise followed by nausea and vomiting, headache, and dizziness He became anuric and lapsed into semi-coma The essential physical findings were cyanosis, icterus, enlarged liver, and a blood pressure of 145/70 The urine had four grams of albumin, many granular and hyaline casts, and many red blood cells He improved under treatment and a check-up one year later showed good renal function A companion of the patient suffered from nausea, headache, and general malaise but recovered in two days

The next report was by Mauro in 1930¹² Five men were engaged in making an insecticide containing potassium soaps, phenol, and carbon tetrachloride One worker, thirty-six years old, developed dryness of the throat, dry cough, and nausea on the first night In five days he suffered headache, vomiting, tremor, and icterus Oliguria set in and leg edema was noticed Physical examination showed an elevated blood pressure, an enlarged liver, and leg edema The urine was scant, acid in reaction, specific gravity 1.011, albumin 3.5 grams, many granular and hyaline casts, but blood was absent The blood urea was 178 mgs The patient recovered in a few days The second case was a man of fifty-two years, who had a similar picture but edema was absent Another worker was mildly ill

In 1931, Hebert and Phelebon¹³ reported the case of an automobile chauffeur of thirty-four years, who became ill while cleaning the chassis of his car with carbon tetrachloride He began to vomit the next day and in two days oliguria developed An icteric tint was noted There was nitrogen retention and reduction of blood chlorides The patient improved rapidly when given salt by mouth

In 1931-32, Lecornu and Pecker¹⁴ de-

scribed the case of a man who was exposed to fumes of carbon tetrachloride for two hours while extinguishing a fire. That night he had headache and nausea followed by vomiting Anuria set in and there developed nasal bleeding, ecchymoses, and purpura Physical examination showed icterus, mild edema of the face, basal râles, and an enlarged liver The blood pressure was not elevated The urine contained a large amount of albumin There was nitrogen retention The patient died in acute pulmonary edema about ten days after exposure.

In 1932, Pogniez, Pichet, and Koang¹⁵ reported three cases occurring in a dye factory The first case, a man of thirty years old, developed malaise the day after exposure and this was followed by vomiting, diarrhea, oliguria, and generalized edema He was admitted to the hospital in acute pulmonary edema Physical examination showed generalized edema and hypertension The urine was scant, contained a good deal of albumin, and the sediment was negative There was nitrogen retention The patient improved rapidly The second case had a similar onset but died within twenty-four hours of acute pulmonary edema The third case, who had been exposed longer than the other two, had no symptoms of intoxication

At the same time Richet and Couder¹⁶ reported another case in a man forty-one years old who became ill with headache and vomiting after exposure This was followed by oliguria and bloody diarrhea The blood pressure was elevated and there was nitrogen retention He was treated with chlorides and calcium and recovered in ten days

McGuire¹⁷ reported seven cases of poisoning following inhalation of fumes of carbon tetrachloride from vats at a felt manufacturing plant Four of the cases had evidences of kidney irritation and one had an acute nephritis The blood pressure in this case was 182/102 The urine was scant and showed evidence of acute nephritis This case was complicated by a bronchopneumonia There was also a diffuse, blotchy, macular rash over the body Calcium, caffeine, and digitalis were used A check-up four months later showed that the patient was well

From the cases reported and from our

the clinical picture was dominated by renal lesion, one similar to necrotizing nephrosis, the other to acute glomerular nephritis. Review of the literature reveals seven similar case reports.

Treatment consists of administering glucose and calcium, the latter acting apparently as an antidote.

The fact that these cases have been

reported in recent years should serve as a warning of the increasing frequency of poisoning from the industrial use of carbon tetrachloride.

NOTE: Since the acceptance of this article, Dudley²⁴ has described four cases from the Royal Naval Hospital, Chatam, England.

LEPROSY ON THE WANE

Leprosy is a disease where the fingers, toes, and even the hands or feet sometimes fall off. Now, by a kind of poetic justice, leprosy itself is falling off. On a population basis there is relatively less leprosy in the world today than ten years ago, Dr Victor G Heiser, president of the International Leprosy Association, and an authority on the treatment of the malady, said at the annual meeting of the American Mission to Lepers in New York City.

Statistics on the history of the disease are misleading, he said, since medical science has recently discovered methods to diagnose the malady at very early stages of its development, thus swelling the number of cases on record as compared with a decade ago.

A specific cure for leprosy has been by no means identified, Dr Heiser said, although not long ago it was erroneously heralded to the world that Trepan blue

was a sure cure. Dr Heiser pointed out that Trepan blue, a dye, is helpful in many cases, but often causes a relapse in the patient. He said somewhat better results had been obtained recently with fluorescin, another dye. Recovery has been achieved in some ten per cent of leprosy cases by the use of chaulmoogra oil, he said.

It may be a long time until better remedies are known, Dr Heiser cautioned, and it is the duty of society to the lepers that they be segregated, cared for and trained to support themselves in so far as possible.

"It is true," he declared, "that leprosy is not transmissible in many localities, why, we don't know. For instance, it is transmissible in this country only in four States—Florida, Louisiana, Texas, and California. But in these regions where it is transmissible, it is absolutely unfair to say that segregation has failed."

THE DOCTOR'S DILEMMA

Lives of great men all remind us
Honest men don't have no chance,
For as we work there grow behind us
Larger patches on our pants

On our pants once new and glossy
Now are stripes of different hue,
All because our patients linger
And do not send us what is due.

Let us then be up and doing,
Send us your mite, however small
For when the snows of winter strike us
We won't have no pants at all

Anonymous, *Ill Med Jour*

that received four c.c. of carbon tetrachloride by mouth were killed after a four days' interval. Fat was found in the tubular epithelium. One dog's kidneys were loaded with brassy tubular casts, but there were no glomerular changes. The rest of their animals, however, showed no changes in the kidneys, not even after alcohol was added to carbon tetrachloride, thereby making it more toxic. When the carbon tetrachloride was given by inhalation to these animals, no change was noted in the lesions produced.

Minot and Cutler²² in 1928, in their work with dogs, found that the most obvious damage was done to the liver. The kidneys showed no striking abnormality except congestion.

Work in the other experimental animals shows no striking lesions in the kidneys, according to Gardner and his group. These workers used rabbits that are very susceptible to carbon tetrachloride. However, Mauro found that in a rabbit exposed to the fumes of thirty-five to ninety gms. of carbon tetrachloride per liter of air for ten days the kidneys were large and congested. The tubules, especially the convoluted ones and those of the descending loop of Henle, showed cloudy swelling. In the cortex there were many small and well-defined zones in which the epithelium of the tubules was desquamated and had fallen into the lumen. No glomerular changes were seen.

In two animals exposed for fifteen to twenty minutes on one occasion, there was very little found in the kidneys. He believed that in animals it took exposure over a period of days to cause renal lesions. Phelps and Hu in their work on guinea pigs found no renal lesions. Chandler and Chopra²³ in administering carbon tetrachloride to cats in doses varying from 0.25 c.c. to four c.c. per kilo found that it was highly toxic. They state that the most remarkable lesions were found in the kidneys. The convoluted tubules showed extensive fatty degeneration and frequently necrosis. The collecting tubules were but little affected. There was often desquamation of Henle's loops. Bowman's capsules were frequently infiltrated with blood, the glomerular endothelium was swollen, and the vessels dilated. In every instance in which they

were able to obtain urine at autopsy there was albumin present and there was frequent evidence of blood.

From the evidence submitted by the above workers it is evident that some animals are more susceptible than others to carbon tetrachloride poisoning, and it is further seen that it may be an individual reaction in any of the animals used as apparently it is in some human beings. One has similar evidence in other drug intoxications.

The treatment is based on the experimental work of Minot and Cutler²² who found that the addition of about five grams of a mixture of calcium carbonate and lactate to the regular meat diet for one to three weeks prior to ingestion of toxic doses of carbon tetrachloride protected dogs from poisoning. The animals on a low calcium diet were much more susceptible to poisoning. These animals had an increased icteric index and a low blood sugar. The blood calcium was normal but the administration of calcium tended to relieve the bilirubinemia and hypoglycemia though it had no effect on the pathological changes in the liver.

Owing to the great similarity between guanidine and carbon tetrachloride intoxication, Minot and Cutler investigated this and found that several hours after the ingestion of carbon tetrachloride there was a rise in blood guanidine and this was followed in a few hours by a fall in blood sugar. Calcium was antagonistic to guanidine and relieved both the hypoglycemia and hyperexcitability. Dextrose was found to relieve the hypoglycemia but not the hyperexcitability. The few clinical reports available have supported the use of calcium and glucose. The good results obtained with chlorides may be due to replenishing the chlorides depleted by vomiting.

Summary

The wide use of carbon tetrachloride in industry and the medical complications that may arise from its use make the recognition of intoxication by this chemical very important.

Most of the reports of intoxication by carbon tetrachloride have dealt with the central nervous system symptoms and gastrohepatic damage.

Two cases are here presented in which

the tree cases, and that an annual check-up is very important

Two important questions arise which we must try to answer *First*, is the perennial treatment more successful than the preseasonal? *Second*, how can we decide when a cure has been achieved—for a cure does occur quite frequently Chart III shows the satisfactory results obtained in about 400 late hay fever

counterbalance this better showing It is difficult for many patients to remember to take their injection each month and if the interval exceeds four or five weeks there is a greater tendency to produce a constitutional reaction The second objection is that a fair number of the perennially treated cases apparently become saturated and develop constitutional reactions on relatively small doses When this occurs

CHART I

patients treated during the five years from 1929 to 1934 inclusive The middle line shows the general average, the lower line those who were treated preseasonally, and the upper line those who received perennial treatment. Clearly, perennial treatment gave consistently about ten per cent better results than preseasonal treatment Two disadvantages tend to

it is wiser to stop all injections for four or five months and begin again with small weekly doses It is our impression that the perennial treatment is more apt to effect a cure, but we have no figures to prove this

The second question invariably put to us is the possibility of permanent relief Recent studies by Walker, Clarke, and

A DISCUSSION OF THE TREATMENT OF HAY FEVER, VASOMOTOR RHINITIS, AND ASTHMA

ALBERT VANDER VEER, M D , *New York City*

During the past twenty-five years the field of allergy has become so broad and has invaded other branches of medicine to such an extent that it would take more time than we have at our disposal merely to skim over an outline of the whole subject. Rather than waste time on this I think it will pay us to discuss in detail a few of the more important questions and procedures in the three main divisions of allergy, namely hay fever, vasomotor rhinitis, and asthma, omitting for the present any reference to urticaria, angioneurotic edema, eczema, migraine, and food and drug idiosyncrasies.

The more time we devote to research and study of this subject, the wider we find its ramifications and there is no branch of medicine where the doctor, whether general practitioner or specialist, can afford to be ignorant of at least the basic principles of hypersensitiveness. As my own experience in the past twenty-five years has been confined almost exclusively to the clinical side of allergy, I would prefer to limit myself to this, leaving the laboratory and experimental discussion to those who are more competent to deal with them.

We probably know more about the treatment of hay fever and have had better success in standardizing our procedures than in any of the other divisions of allergy. It is generally admitted that injections of pollen extracts will yield at least eighty per cent satisfactory results in at least eighty per cent of our patients, granted that the proper pollens have been selected and the proper doses given. Diets, acid or alkali therapy, local treatment with cautery, electricity or ionization, and many more methods have been tried from time to time, but in the long run have failed. In selecting the proper extracts to be used, two kinds of pollen charts are of great assistance to us. Chart I gives a bird's eye view of the pollination period of most of the important air born pollens of northeastern United States. It is made up from day to day observations by

a trained botanist in the field, averaged over a period of several years. By comparing the patient's seasonal history to this chart we can roughly determine what pollens may be causing his trouble. Chart II combines a chart of the daily variation in density of pollen of several of the important trees with a chart of the daily severity of the patient's symptoms. This is most essential for, while the intradermal tests will tell us to which pollens the patient is hypersensitive, they will not tell us to which he is exposed and this chart furnishes us with the missing data.

The patient in question, a doctor, came to us in March 1933, with a history of hay fever from the end of March to mid June. He gave good skin reactions to a dozen different pollens and an effort was made to combine these all in one mixture which resulted in his receiving very little of each pollen and very little relief from his hay fever. His injections were continued through the winter and thus larger doses were reached in 1934 but they were still inadequate. In 1935 three separate mixtures were made each containing from two to four pollens, and by giving these on different days, it was possible to reach much higher doses. Particular attention was paid to birch and oak. This was apparently successful as he had no hay fever after April 27. But here a new phenomenon presented itself in the severe attack lasting from March 17 to April 27, a period when he had been practically free in 1933 and 1934. Comparing this to the pollen chart shows that it almost exactly coincides with the elm pollination. He had given a good skin reaction to elm but as heretofore there was little trouble at this period, his dose of elm pollen was very low. It is reasonable to believe that an increase in dosage this year may give him as complete immunity as to the birch and oak.

While this is an extremely complicated case, sensitive to many different pollens, it demonstrates that with care and with cooperation on the part of the patient, a satisfactory result can be obtained. It also shows that hypersensitiveness may change from year to year, particularly in

asthma Removal of tonsils and adenoids does not clear up the tendency as it so often does in the non-allergic patient By the age of ten the youngster will be lucky if he has not had at least one attack of pneumonia and possibly a mastoid At twelve or thirteen a school in Arizona is suggested and this works splendidly for the child but not so well for the family or father's pocketbook At eighteen or twenty he has outgrown most of his trouble and can come east again, but by thirty he is quite apt to develop sinus infection or asthma If he is not lucky enough to get the change in climate his sinus infection may come much earlier A large number of children with such a history are hypersensitive to dust, feathers, etc., and with proper attention early in life they can be made over into healthy, husky youngsters perfectly able to stand their native climate and no more susceptible to sinus infection and pneumonia than their comrades The time to do this however, is before any damage has been done and it is the duty of the family physician to see that it is done just as he recommends diphtheria immunization, vaccination against small pox, and other protective measures

As vasomotor rhinitis is one of the most important and at the same time one of the most neglected fields of preventive medicine, the following case histories are presented to illustrate the points involved

Boy, aged ten, was referred to us October 17, 1925, with a history of vasomotor rhinitis and late hay fever for five years, no asthma His older brother also had vasomotor rhinitis with sinus infection and early and late hay fever On examination his sinuses lighted clearly On testing he gave marked reactions to timothy, plantain and ragweed pollens, and house dust During the winter of 1925-26 he was treated with injections of dust and stock cold vaccine. He was allright with the exception of slight colds in April and May Through the summer of 1926 he was given pollen injections and had practically no hay fever His dust and vaccine injections had been discontinued in the Spring and in November 1926 he had a bad case of grippe and bronchitis After this they were resumed and he did well from January through the rest of the winter He had a good deal of hay fever during the summer of 1927 due to underdosage of his pollen extracts His last course of dust and cold vaccine was given in 1928

but his pollen injections were continued through every summer from 1929 to 1932 During this time he had no hay fever and averaged about two colds a winter He has had no treatment for the past four years and while he still has an occasional cold and would probably benefit with another course of dust and vaccine, he is as healthy as the average boy of his age and has so far escaped any operation on his sinuses and shows no tendency to develop asthma Much credit must be given his mother who insisted on bringing him to our office year after year against the strenuous opposition of a normal boy I am sure that her perseverance has saved him a lot of trouble and probably some disagreeable nasal operations

A similar condition but with a different outcome is presented in the next case history

Boy referred to us in 1929 at the age of eight. He had had eczema since infancy and was originally egg sensitive but had outgrown this He had many winter colds and had had early and late hay fever for four years He had been tested but never treated Six months earlier he had had a mastoid operation and was partially deaf in one ear On testing he gave marked reactions to grass and ragweed pollens and to house dust He was negative to egg white. For the past six years he had been treated with monthly injections of pollen and dust extracts and cold vaccine His hay fever is negligible but he still has an occasional winter cold His general health is excellent except for the partial deafness While it cannot be proved, I have a decided feeling that if he had been treated for his dust sensitiveness and hay fever several years earlier, he would have been saved his mastoid operation and deafness which he will carry through life

In considering the next division of allergy, namely asthma, we encounter more difficult problems than are met in hay fever and vasomotor rhinitis, and consequently our success is less striking At the outset we must divide our cases into four main groups, *first* those hypersensitive to inhalants as pollens, dust, and animal danders This group offers comparatively little difficulty and yields to treatment almost as readily as the simpler nasal conditions The *second* group comprises those hypersensitive to foods and drugs There are fewer of these and they can usually be solved by careful history, test diets, and judicious testing In the *third* group are patients hypersensitive to inhalants but with a complicating sinus

CHART II

others show that from thirty to fifty per cent of hay fever patients may eventually become cured but that this usually occurs only after five or six years of successful treatment. It is extremely difficult to determine when this result has been obtained as in our experience (which does not agree with some other workers) the skin reaction usually remains positive. Laboratory tests with serum have so far failed to help us in this determination, but a fair clinical test may be made by treating a patient who has done well for four or five years up until the beginning of the season and then stopping all injections. If hay fever develops during the season it can be quickly controlled by another injection, but if the patient goes through the entire season without injections and remains free from symptoms the probability is that he will continue for one or more years with little or none.

Chart III also demonstrates the reasonable conclusion that the more pollen in the air, the poorer will be our results. The top line shows the total ragweed count for each of the five years and the satisfactory results obtained vary inversely with this curve.

Vasomotor rhinitis is another division in the field of allergy where intelligent treatment often yields excellent results. We have all seen cases where the avoidance of feathers, orris or household pets has caused a disappearance of the symp-

toms, but far and away the most important factor to be considered in this condition is ordinary house dust. Treatment with this extract in certain cases of vasomotor rhinitis and asthma has relieved the condition in an even more striking and favorable manner than have pollen extracts in hay fever. It cannot be emphasized too strongly that no patient should be operated on for sinus infection or similar nasal disturbance without first being tested out at least with the inhalant group and particularly with house dust. If this is done many a patient will be saved a septum resection or a sinus operation which seemed inevitable and many a poor postoperative result can be made completely successful if proper attention is paid to the associated allergic condition. Failure to investigate the possibility of a hypersensitive condition may prove particularly costly in the so-called dust sensitive child. The story of such a case is very characteristic. There is usually a family history of allergy. Almost from birth the patient shows an extreme susceptibility to head colds and after entering school is laid up every month or so with a respiratory infection usually with a complicating bronchitis and occasionally

CHART III

three classifications are used + + + denoting complete or practically complete relief from asthma, + + marked improvement, at least to such a degree that they could return to work, and + showing little or no improvement in their condition

By the term complete surgery is meant that all foci of infection were removed

TABLE I—POSTOPERATIVE FOLLOW-UP PERIOD

Asthma (173 cases)			Results		
			+	++	+++
1 to 1 year	26		12	7	7

which in the judgment of the operator and the allergist should be removed. By incomplete surgery is meant the removal of one or more foci but that something was left undone, either because of unwillingness or inability on the part of the patient, which in the judgment of the doctors should have been done.

Combined allergy means that some degree of hypersensitiveness was added to the infection while the purely infective cases showed no demonstrable hypersensitiveness.

Taking the entire group fifty-two or thirty per cent showed no improvement after a lapse of six months to six years following operation, sixty-four or thirty-seven per cent showed decided improvement and fifty-seven or thirty-three per cent were considered practically cured. Adding groups two and three together we find that seventy per cent of these asthmatic patients were definitely improved after operation on their sinuses. When we separate these figures into the

patients where the operator was allowed to do as he wished, we get at the real root of the matter. Where so-called complete surgery was done seventy-four out of eighty-eight patients or eighty-four per cent were definitely or completely relieved of their asthma, leaving only sixteen per cent not benefited, while in the group with incomplete surgery thirty-eight or forty-four per cent received no benefit at all, and forty-seven or fifty-six per cent were greatly relieved or cured. This shows that a thorough job is worth while.

Strange to say, the addition of hypersensitiveness to the infection did not make for a worse prognosis, in fact somewhat to the contrary, as eighty-eight per cent of the completely operated, combined allergy cases showed improvement as against seventy-nine per cent of the completely operated pure infective cases and even with the incompletely operated group, seventy per cent of the combined cases did well, as compared with forty-five per cent of the pure infective ones.

While these results are far from perfect, they do give cause for optimism when we consider that in such a serious condition as asthma secondary to sinus infection, two thirds of our patients at least may be cured or greatly benefited by proper operative interference. Emphasis should also be placed on the eighty-four per cent satisfactory results where the operator was allowed to follow his own judgment as against the fifty-five per cent improved following incomplete surgery. It certainly seems reasonable to bend all our efforts toward doing a complete job.

The last point I would try to make is that it may take some time to reach the maximum of improvement and that in the completely operated cases only a little over ten per cent showed no benefit after two years.

The following two case histories illustrate several of the points I have tried to bring out.

Asthma secondary to sinus infection with no complicating hypersensitiveness. Female, aged sixty-four, referred to us in February 1929 with a history of asthma of ten years, worse in winter. She was negative to all the inhalant and food tests with the exception of slight reactions to green pepper and turnip which obviously had nothing

infection The *fourth* group consists of cases secondary to sinus infection in whom no hypersensitive condition can be demonstrated Our greatest difficulties arise in treating those who fall in the two last groups and particularly those who have asthma secondary to sinus infection without complicating hypersensitiveness

It is from the patient in this fourth group we so often hear the question "Doctor, can you do anything to help my asthma? I have tried everything to no avail, and my friends say that asthma is incurable" A fair and honest answer to this question may be phrased as follows, "If we can clear up the infection causing your asthma, if you are willing and able to spend enough time and money and will consent to such surgical operations as may be necessary to eradicate foci of infection, then we may offer you the hope of complete cure or at least comparative comfort and the restoration to a useful life"

In this answer you have covered the main causes of failure in the treatment of asthma There are a few patients with extensive sinus or bronchial involvement or with a mold infection of the lungs to whom we can at present offer little hope There are many patients unable or unwilling to spare either the necessary time or money, or who refuse to undergo the unpleasant surgical procedures their condition may demand If you tell a man that he has tuberculosis and must spend a year of his life and several thousand dollars in order to get well he will manage to get away from his job and raise the necessary funds somehow If you tell an asthmatic that he needs a radical antrum operation which will keep him in the hospital for two weeks and should be followed by several months of recuperation he will often insist that he can spare neither the time nor the money and that he prefers to experiment with the Hay diet or ten drops of hydrochloric acid three times a day At the end of a year or so wasted in such foolish temporizing he may come back asking for relief (although he usually goes to some other doctor this time) and by then it is often too late This seems like an exaggerated picture, but it happens so frequently that I think we must face the facts After a campaign of many years the public has

become tuberculosis-conscious and realizes what the penalty of neglect may be. In the same way the public should be taught the price which may be paid for neglected or insufficiently treated asthma

Another barrier we confront in many of the intractable cases is the defensive remark "But doctor, I have already had several operations and they only helped me for a short time" This emphasizes the necessity for teamwork in our work The general practitioner can handle the majority of asthma cases successfully The more difficult ones require the services of a modern allergy clinic Here we have not only an allergist and a nose and throat surgeon operating in close cooperation, but in addition a general medical man, bacteriologist, chemist and botanist, with complete x-ray and laboratory facilities all uniting to determine what type of operation is to be done and what supplementary treatment in the form of vaccines, extracts, and general medical care are necessary In the olden days a surgeon might remove an appendix by lamp light, working on a kitchen table, with only an untrained assistant to help him, but we certainly do not believe that delicate abdominal or brain operations can be performed successfully today without the elaborate equipment of a modern hospital

Table I shows a tabulation of the results in 173 patients operated on in our allergy clinic at Roosevelt Hospital and in our private practice for the relief of asthma secondary to sinus infection As far as possible these patients were thoroughly worked up, both before and after operation They had a general physical examination, with the necessary laboratory tests They were completely tested out, and treated for their hypersensitiveness, if present Vaccines were frequently made from tissue removed at operation (not simply from superficial swab cultures) These vaccines were used with extreme care, for patients with sinus infection are often exquisitely sensitive to vaccine injections After care and general tonic treatment were not neglected All this was extremely important as most of these cases had already had one or more operations which had not resulted in the hoped-for cure

In studying Table I you will note that

MANAGEMENT OF EARLY SYPHILIS

FRANK C COMBES, M D , *New York City*

Clinical Professor of Dermatology and Syphilology New York University College of Medicine

The elimination of syphilis as a social, economic, and physical menace can be best accomplished by the effective management of the disease in its early phases, and by recognition and treatment in the pregnant infected woman. The former is of greater import, because of its numerical predominance, the greater difficulty of individual control, and its relatively greater infectiousness.

An effort to standardize the treatment of the disease in its early stages is justified for these reasons:

- 1 It occurs usually in healthy young adults who can best withstand the physical strain of treatment.

- 2 There is a certain uniformity to the infection at this time, warranting a certain uniformity of treatment.

- 3 Proper treatment administered at this time will result in eighty-nine to ninety-five per cent cures, far in excess to what may be expected at any other stage of the disease.

By early syphilis is meant that phase which elapses between the appearance of the initial lesion, through to the disappearance of the generalized cutaneous efflorescence. In those cases which present no generalized eruption, it may be considered to extend over a period of approximately three months from the appearance of the initial lesion. This corresponds roughly to the period of dissemination of the disease. The earlier treatment is instituted, the higher is the percentage of absolute cures. There should be no curtailment of treatment because it is initiated in the early seronegative phase.

Before treatment is undertaken, a definite diagnosis must be made on laboratory evidence, either by dark-field demonstration of the *Spirochete pallida* from the initial lesion or regional lymph nodes, or a positive properly interpreted serologic complement-fixation test. Under no condition should treatment be instituted on the grounds of a clinical diagnosis of a primary lesion alone. The absolute clinical differentiation of a primary

lesion from other granulomatous ulcers, erosions, and nodules of a nonsyphilitic nature is not possible. The therapeutic test has no place in the diagnosis of the initial lesion. If treatment with one of the arsphenamines is begun before a positive diagnosis is made, not only will the medication destroy the significance of subsequent serologic tests and nullify subsequent efforts to demonstrate the causative organism, but will implant an element of doubt regarding the diagnosis in the mind of both patient and physician, which experience has shown leads to an inadequate and indecisive course of treatment. This results in serious visceral complications in later life. I would rather rely solely on the mercurial pills andunctions of Hutchinson and Fournier, than to treat a patient with a recent infection inadequately or with a therapeutically inferior arsenobenzol. Experience reveals that, as a rule, the patient receiving no arsenobenzol at all is less subject to serious visceral involvement in later life, than one who receives it in insufficient quantities.

After a diagnosis of syphilis has been established, certain measures are indicated. These include a thorough examination of the patient with special attention to the gastrointestinal tract, heart, and renal systems. The teeth and sinuses should be examined to eliminate any remote focus of infection which might seriously impair the health of the individual, or predispose him to unfortunate and serious reactions to arsenical medication. Oral cleanliness is important and should be maintained throughout the entire course of treatment. Disorders of digestion, if present, should receive attention and a daily movement of the bowels be insisted upon. The hepatotoxic nature of the arsenobenzols requires that the liver activity be normal especially its glycogenic function. Some obscure gastrointestinal reactions to the arsenobenzols may be avoided by the administration of glucose intravenously, or by

ALBERT VANDER VEER

[N Y State J M.]

to do with her condition. On examination, she showed a pansinusitis. She was treated for several months with antral irrigations and injections of stock and autogenous vaccines. As there was no particular improvement in her condition, permanent windows were made in both antra. Following this, she did well for a year, her only attacks of asthma being those brought on by overdoses of vaccine. Her asthma then gradually increased in severity and she developed extensive polypoid degeneration of the ethmoids. In December 1930, extenteration of the left ethmoid and sphenoid was done, followed by a bilateral, complete antrum operation. Since then she has done very well. Occasionally she develops a cold with mild asthma for a day or two, but at seventy she is still working hard all year round.

In July 1934 she developed polyps in her right ethmoid and sphenoid and these were removed. Her present treatment consists of a vaccine injection about once a month. The last examination of her nose in December 1935 showed it to be in excellent condition. With the experience gained from similar cases in the last ten years, we are inclined to feel that much time and trouble may be saved by a complete operation earlier in the course of the disease rather than temporizing with constant antral irrigations and antral windows.

Combined infection and hypersensitive

Female, aged forty-seven, referred to us in September 1933 with a history of vasomotor rhinitis for eight years and beginning asthma. In 1923 polyps were removed from her nose. Six years later she had a double radical antrum operation, but within six months polyps were again removed. Two years later another sinus operation was performed. In other words, she had had extensive nasal surgery performed by a competent operator over a period of ten years, not only with no improvement in her condition, but actually the development of asthma made the outlook much more serious. On examination, she showed a pansinusitis with extensive polypoid degeneration. On testing, she gave marked reactions to house dust and ragweed, but was negative to all the other inhalants and foods. She was started on dust and ragweed injections, but as she came to us in the middle of the hay fever season, she had a pretty stormy time of it for a month. On October 16, 1933 we persuaded her to go to Roosevelt Hospital in an air-conditioned room for an environmental test. Her asthma promptly cleared up, which made us feel that her hypersensitivity was at least as important as the infection. By October 23 she had improved sufficiently to have a bilateral ex-

enteration of ethmoids and sphenoid with the removal of a number of polyps. She made an uneventful recovery. Dust and ragweed injections were continued through the winter and to them were added small doses of stock and autogenous vaccines. She went through the winter of 1933-34 with an occasional slight cold, but no asthma. The summer of 1934 had very little hay fever. Dust and vaccine injections were omitted in the winter of 1934-35 but she had little or no trouble. Ragweed injections have been continued and last summer (1935) she had no hay fever at all. In November 1935 she had an attack of asthma due to exposure to dust and coal gas while moving. Examination of her nose on November 25, 1935 showed it to be perfectly free and clear of infection. What a tremendous amount of trouble she would have been saved if she had been completely examined when the vasomotor rhinitis first appeared!

Urticaria and angioneurotic edema secondary to infection. Male, aged forty-seven, referred to us January 14, 1933 with the history of migraine and indigestion for many years, vasomotor rhinitis about two years, and urticaria and angioneurotic edema for the past month. He felt sure that some food was to blame and suspected ham, pigs' knuckles, sauerkraut, and grapes. On examination he showed many foci of infection including tonsils, many non-vital teeth, and a cloudy right antrum and ethmoid. His antrum was irrigated on January 16. Within two days the urticaria had practically cleared and was entirely gone after a week. A few food tests were done showing moderate reactions to rice, tea, and coffee, and a negative reaction to pork. Eight infected teeth were extracted and the right ethmoid extenterated, followed by a right radical antrum operation. He was then given injections of autogenous vaccine. Improvement was gradual through that summer. He was again seen in February 1934, and at that time had gained seventeen pounds. Hemoglobin had risen from sixty to eighty-two per cent. He was eating everything without indigestion and had no more urticaria. The patient was not seen again for two years. During that time he was perfectly well except for some nervous complaints. He stated that recently he had begun to have about one hive a week. On examination it was found that his tonsils were still large and infected and his left anterior ethmoid showed extensive polypoid degeneration. We feel that this ethmoid infection, plus his tonsillar infection is the cause of the recurrence of his hives, and we made plans for operations to remove the last source of infection.

which cannot be overestimated. You will be rewarded with a patient who will co-operate, anticipating the day when he will again be a healthy, disease-free individual.

The social problems of his infection will bear some investigation. Syphilis constitutes a social danger from four points of view:

- 1 By the damage which it inflicts on the individual
- 2 By the damage it inflicts on the family
- 3 By its hereditary consequences
- 4 By its degenerative effect on the race

Every person with syphilis must be considered, not merely as an individual, but as an integral working part of the community. What effect has his infection had upon his family, both medically and economically? Are other members of the community infected, or are they likely to be subsequently exposed to infection? This must be exhaustively discussed with the patient and appropriate measures must be taken for examination and protection of contacts. The patient should be informed as to the infectious nature of the disease and of the various avenues through which he may accidentally convey it to others. Fortunately a week of anti-syphilitic therapy renders contagion by ordinary immediate and intermediate contact negligible. In addition, the *Spirochete* is not a viable organism outside of the host, dying immediately on drying. For this reason, the presence of the disease in food-handlers is no menace to community health. Furthermore, I have never seen an infection conveyed by means of food, tableware or the privy. However, a great deal can be accomplished from a public health standpoint by considering the potential danger to the community of the infectious patient. In addition, it is the duty of the physician to determine in each individual case, if possible, the source of infection. With few exceptions, which can be handled privately, these sources should be reported to the local public health authorities.

We now come to the third consideration, namely the specific treatment, directed toward the eradication of the infection. The chancre requires no local specific medication. The secret of success lies in the individualization of the patient and the proper administration of well-

proven spirochetocidal drugs. In no case should the treatment be limited to a single remedy. In no disease have we such a formidable array of chemicals of such proven value as in syphilis. Make intelligent use of them. If the patient does not respond to one, after sufficiently intelligent trial, lose no time in administering another remedy of different chemical structure, which is capable of attacking the infection from another, possibly more vulnerable point. Rely more on your own experience and that of competent clinicians in selection of drugs. Avoid claims and advice of manufacturers and advertisements.

The curability of the disease depends, in a large measure, on the time treatment is first instituted. Treatment begun in the seronegative phase, on the basis of the dark-field demonstration of *Spirochete pallida*, materially increases the probability of complete eradication of the infection.

The arsenobenzols—arsphenamine, neoarsphenamine, silver arsphenamine, sodium arsphenamine, and sulpharsphenamine—are the most potent spirochetocidal agents at our disposal. Recently introduced is a preparation of oxidized arsphenamine, called Mapharsen, which promises to be a very useful spirochetocide. It has not yet, however, had sufficient clinical trial to warrant its general use in early infections.

The arsenobenzols are most effective during the early period of dissemination of the spirochete throughout the organism. This is not only a great advantage from a therapeutic standpoint, but since they produce rapid sterilization of superficial lesions within a few hours, they remove the patient as a menace to the community.

The arsenobenzols have four serious disadvantages:

- 1 They cannot penetrate tissue which is poorly vascularized.
- 2 They cannot penetrate the nervous system in appreciable quantities.
- 3 They are neurotoxic, due to their arsenic content.
- 4 They are hepatotoxic and have a depressing effect upon the bone-marrow, probably due to their benzol derivation.

Therapeutically, there is little apparent difference between the various preparations, if given in proportionate dosage.

advising the patient to eat several pieces of candy or some glucose a few hours before its administration. This seems to fortify the liver and lessen the possibility of damage to that organ.

The urine should be examined, especially for albumin, sugar, and indican, before treatment is started and again at biweekly intervals during the treatment, so that upon the appearance of renal irritation, treatment may, if advisable, be modified. However, the appearance of traces of albumin and a few casts during treatment if not accompanied by nitrogen retention, is no cause for alarm. In most cases, the urine clears upon completion of the antisyphilitic therapy. I have never seen any serious damage inflicted upon a healthy renal system by properly administered heavy metals.

The heart should be examined organically and functionally. It might be advisable to obtain an electrocardiogram, so that a permanent graphic record of cardiac function is available for comparison with any future involvement of that organ which might supervene. A myocardium previously injured by rheumatic infection is more prone to attack by syphilis than a healthy organ.

A complete cytologic examination of the blood should be made before treatment is begun and repeated at intervals. Bismuth and the mercurials have been responsible for the development of simple anemias, and the arsenobenzols, particularly neoarsphenamine and sulpharsphenamine, are capable of producing fatal blood dyscrasias of the agranulocytic type.

The patient should then be interviewed and advised regarding the hygienic, economic, and social aspects of his infection. Physical disorders of all types having been corrected, and the patient having been put in condition to withstand not only the ravages of the syphilitic virus, but also the chemotherapeutic shock of the spirocheticidal drugs, he should be informed of the advisability of leading a temperate life. He should have adequate and appropriate exercise, sunlight, fresh air and recreation, and a nutritious well-balanced diet. This is as important in this infection as in tuberculosis. He should be advised against over-

indulgence in spiritous liquors. There is no doubt that overindulgence in alcohol predisposes to nerve and vascular complications of a serious type. The use of tobacco also should be modified. Mucous patches and leukoplakia are more common in those who use tobacco.

One of the greatest difficulties which confronts the syphilologist in some cases is to successfully control the neuresthenia with which the patient is afflicted. This frequently requires greater therapeutic resourcefulness than the syphilophobia of the noninfected individual.

In addition to the general medical problem, one must discuss with the patient the economic questions, which are of mutual interest both to him and the physician. The patient must be fully informed of the approximate cost of treatment, and subsequent periods of observation necessary to insure complete eradication of the infection. In other words, there must be honest and complete cooperation between the patient and physician. The cost of treatment must not be prohibitive. It should be based on the income of the individual. If this is not taken as a basis of cost, one is likely to discover that intervals between treatments will shortly be regulated by the patient's ability to pay, and eventually, treatment will be prematurely discontinued entirely, at a time when its vigorous continuance should be of essential importance. Unfortunately, infection with syphilis occurs usually in young individuals when their financial status is very limited. The greatest number of infections occur in women at the age of twenty years, and in men at the age of twenty-three years. Later in life when the disease has reached so-called latency, complete and permanent cure cannot be assured at any price.

In early cases, one should assure the patient that he *can be cured*. Among the laity, there is a general impression that the disease is incurable. The patient approaches his physician with great apprehension, and hesitatingly asks, "Can I be cured?" He hopes for an affirmative reply, but anticipates a negative one. If you can assure him that with proper attention he will rid himself of the infection and will be able to marry and rear healthy children, you will have removed a burden from his mind, the importance of

which cannot be overestimated. You will be rewarded with a patient who will co-operate, anticipating the day when he will again be a healthy, disease-free individual.

- 2 They cannot penetrate the nervous system in appreciable quantities.
- 3 They are neurotoxic, due to their arsenic content.
- 4 They are hepatotoxic and have a depressing effect upon the bone-marrow, probably due to their benzol derivation.

Therapeutically, there is little apparent difference between the various preparations, if given in proportionate dosage.

Neoarsphenamine and sulpharsphenamine give rise more frequently to delayed toxic effects.

Silver arsphenamine, which contains fourteen per cent silver, may on rare occasions, cause argyria. Its arsenic content is approximately the same as neoarsphenamine. Neoarsphenamine, because of its ease of administration, is used almost exclusively in Europe and is by far the favored preparation in this country. Some syphilologists consider arsphenamine therapeutically superior to neoarsphenamine. However, while the former is apparently more efficient in healing infective lesions, I believe that in sufficient dosage neoarsphenamine compares very favorably with it. Mercury, the oldest of remedies, has a very definite place in our therapeutic armamentarium. It should not be forgotten, nor its use neglected. Frequently a case will respond to it when more modern remedies have failed. I am not one of those of the opinion that no case of syphilis can be cured without arsenobenzol. I hesitate to think that such worthy syphilologists as Fournier, Hutchinson, and Renaut failed to ever rid a patient of the disease.

Bismuth, introduced by Levaditi in 1921, has nearly displaced mercury in the treatment of the disease. It has certain advantages over the older metal, particularly in that it is therapeutically more active, and is relatively less painful on injection. In addition, it may be given in the form of salts which are lipo-soluble, more easily dissociated, and have a greater affinity for the reticulo-endothelial system. However, it cannot be effectively administered by mouth or byunction.

Classifying our specific drugs, according to their influence on the symptoms of syphilis, as well as the causative organism, we must place the arsphenamines far above the others, giving second place to bismuth and third to mercury.

Various clinicians have from time to time advocated different methods of routine treatment of early syphilis. Most of these methods are satisfactory and based on accurate and extensive clinical observations. It is not necessary to discuss them in detail. However, certain principles should be considered in any routine treatment.

1 It should be instituted with arsenobenzol of sufficient dosage.
2 The intervals between the administration of arsenobenzol should be regulated according to the excretion of the product. This varies initially from approximately forty-eight to seventy-two hours, increasing as administration is repeated until the maximum excretion is completed in five to seven days.

3 Treatment of early syphilis should be continuous from twelve to eighteen months, with a period of subsequent observation extending over five years.

4 A total dosage of twenty to thirty grams of neoarsphenamine or its equivalent should be administered.

5 A total of two to three grams of bismuth element should be administered or an equal amount of mercury. Proportionate amounts of each may also be administered. You should be familiar with the amount of element present in the preparation used.

6 Treatment should be ended with a course of approximately one gram of bismuth or mercury, rather than arsenobenzol.

Schermerhorn of Schenectady informs me that he has been obtaining good serologic and clinical results using continuous weekly injections of neoarsphenamine, with simultaneous administration of interrupted courses of a heavy metal.

Roby of Rochester, (N Y) for the last ten years has been giving sulpharsphenamine continuously. His objective is to administer forty consecutive weekly treatments to every patient. Up to last year he had administered well over 60,000 injections. He uses no heavy metals unless the patients are unable to continue with the sulpharsphenamine. This rarely occurs. His results have been very good. Such methods shorten the time of treatment but would require close observation of the patient for evidence of arsenic intoxication. There is also evidence to show that neglect of heavy metals results in a tendency to the "neuro-recidives" of Ehrlich. This type of neuro recurrence increased perceptibly immediately after the introduction of salvarsan therapy. The reason for this has been explained on the basis that enthusiasm over the new arsenical had resulted in insufficient mercurial therapy. It can be prevented by proper administration of sufficient heavy metal in conjunction with arsphenamine.

My own method (Table I) has afforded

excellent results over the last ten years. Although the arsenobenzol and type of heavy metal salt have varied, in principle the routine in most cases has been the same.

It is important that the physician familiarize himself with the preparation he is using. There are many preparations of arsenobenzol available, which, although spirochetocidal, vary considerably in

sociation. Many of them contain small amounts of arsenic as a contaminant. Whatever preparation is used the syphilologist should be familiar with its bismuth content, the vehicle, and its rate of absorption and excretion. This will help to regulate the dosage and frequency of administration. If you are using certain preparations and are satisfied with them, do not change, except for good and sufficient reason.

The administrative technic of the arsenobenzols can be learned only by actual observance and practice. They are administered intravenously with the exception of sulpharsphenamine which is given either intramuscularly or subcutaneously. While I do not consider it as safe, nor in conservative dosage as effective as the others, Pfeiffer of Albany tells me that he has had excellent results with it and a remarkable freedom from toxic effects over a period of twelve years. He uses a maximum dosage of 0.45 gms considering this quite as effective as neoarsphenamine intravenously. It is of value when intravenous therapy is contraindicated or impossible, because of the small size or depth of the veins. If the perivascular tissues should be accidentally infiltrated with one of the arsenobenzols, a few cubic centimeters of a 0.5 per cent novocain solution containing one per cent sodium thiosulphate should be injected immediately into the infiltrated tissues. The overlying skin should be painted with two per cent oil of mustard in alcohol until reddened. Cold compresses should be applied the first day and subsequently hot compresses.

Bismuth is best administered intramuscularly. The dosage is measured at approximately 0.5 mgm bismuth (element), per kilogram, per day. I prefer, as a bismuth preparation, a colloidal bismuth hydroxide suspended in oil, containing 100 mgm of metal to the cubic centimeter. It is administered in doses of 0.5 to 1.0 c.c., is painless, causes no infiltration, and does not accumulate at the site of injection. Being very readily dissociated, it is quickly ionized, liberating free bismuth. It is more slowly absorbed than the insoluble preparations. As an alternative, I use a finely divided bismuth sub-salicylate oil suspension, which contains about sixty per cent metallic bis-

*A rest period of six to eight weeks may be allowed between the third and fourth courses of neoarsphenamine.

therapeutic activity. The efforts to prepare a product of lessened toxicity to the host have resulted frequently in one of lessened therapeutic value, although conforming to government standards. Over a hundred preparations of bismuth salts and metallic bismuth suspensions are advertised. These vary in their efficacy because of their varied bismuth content, rate of absorption, excretion, and dis-

muth, in doses of one to two cm This is one of the more widely used bismuth salts Soluble bismuth plays a minor role It is necessary to administer it at too frequent intervals for convenience, it does not maintain a good constant level of saturation in the tissue, and in addition its rapid excretion produces undue renal irritation Sodium potassium tartrobismuthate is a good example of a soluble preparation, containing forty-one per cent bismuth element It is administered in doses of 0.1 to 0.2 gm

Mercurials in general are of three types, soluble, insoluble, and colloidal Of the soluble preparations, the bichloride, succinimide, and biniodide are in general use Because of their rapid absorption and excretion, they should be administered daily or every other day, in doses of 0.1 to 0.15 gm intramuscularly They are all quite painful The insoluble mercury salicylate in oil suspension is less painful and slowly absorbed and excreted This is a decided advantage It is administered intramuscularly, in doses of 0.6 to 1.2 gm every five to seven days Two colloidal preparations are in general use, namely, the sulphide and calomel I prefer the latter It is given intravenously in doses of five cc every three days Each dose represents 0.1 grams of mercurous chloride It is slowly ionized Hazen considers calomel the most powerful antisyphilitic drug at our disposal, with the exception of arsphenamine and neoarsphenamine I find it of definite value in early cases in which arsenobenzol, for some reason or other is contraindicated It is also effective in early eye complications which do not respond well to the arsphenamines

There are certain drugs which frequently have a very definite role in the treatment These are not specific, but indirectly exert a favorable influence They are iron, sulphur, and iodides I have never seen any indication to administer the latter in early syphilis although some clinicians favor their use They are very likely to upset the digestion and produce objectionable cutaneous eruptions These untoward reactions are not as common in late syphilis when the iodides exert a very definite favorable influence Iron is frequently indicated as a tonic and in combating the anemia in-

duced in some cases by mercury and bismuth It may be administered by injection or by mouth In utilizing the latter route, care must be taken not to interfere unduly with the patient's digestion or evacuation

Sulphur plays a very definite role Its action is to encourage the excretion of inert arsenic and the heavy metals It forms soluble and easily eliminated compounds, favoring recovery from toxic effects of saturation Arsenic and the heavy metals are retained in varying amounts in the organism for an indefinite period This storage is therapeutically ineffective, as the heavy metals are only spirochetocidal in their transit through the body Elemental arsenic is not spirochetocidal McMurtry aptly expressed the action of sulphur by saying that it kept a continuous flow of heavy metal passing through the body It is best administered as sodium thiosulphate or as a colloidal sulphur intravenously It should not be given during a course of arsenobenzol as it interferes materially with the spirochetocidal action of that drug

At the completion of the second course of treatment, a complete examination of the spinal fluid should be made This can be obtained with no discomfort to the patient by means of suboccipital puncture The examination should include cytology, complement fixation, gold-curve, and chemical examination The latter should include a quantitative globulin estimation A normal result at this time will obviate the necessity of repetition of the examination Experience has shown that infection of the central nervous system occurs during the period of dissemination of the disease, although clinically it may not reveal its presence for years

I have tried to emphasize briefly a few of the important considerations attending the treatment of early syphilis Certain of them must be modified, depending upon the needs and requirements of the individual case Always familiarize yourself with the efficiency of the organic functions of the patient, the vagaries of the Spirochete, and with the physicochemical properties of the remedies used in combating the infection

SUCCESSFUL SUTURE OF A PENETRATING STAB WOUND OF THE HEART

JOSEPH B STENBUCK, M D, F A C S, *New York City*
Visiting Surgeon, Harlem Hospital

J M, a Porto Rican male, age twenty-three, was admitted to the Harlem Hospital, October 18, 1934. He had received three stab wounds. He was unconscious and therefore it was impossible to determine how long before admission he had sustained them. Nor could he remember the time interval even when he regained consciousness after operation. He was pulseless and his blood pressure was zero. He breathed stertorously. His skin was cold and sweaty and the conjunctivæ were pale. Examination of the chest showed a tympanic percussion note and distant vesicular breath sounds throughout the left hemothorax. In the right side of the chest, there was a normal percussion note and the breath sounds were vesicular in character and easily heard. While the area of cardiac dullness was replaced by a tympanic area on the left, the right border of cardiac dullness extended one and three-quarter inches beyond the right border of the sternum. The heart sounds were muffled and rapid. No murmur or bruit was heard.

The three wounds were situated as follows (1) in the fourth interspace, one inch from the left sternal border, (2) in the right midclavicular line in the seventh interspace, (3) in the left posterior axillary line in the tenth interspace.

The patient was apparently suffering from a penetrating stab wound of the heart and therefore, it was thought advisable to explore the chest and observe the abdomen further for possible intra-abdominal injury. The heart injury was properly diagnosed by the admitting physician and the patient was sent directly to the operating room.

Operation. Incision was attempted under local anesthesia but since the patient, though unconscious, moved about on the table, ether was administered. The incision, which is indicated in Fig 1 was carried down to the ribs, and the flap containing skin and the underlying portion of pectoralis major muscle was turned back in one piece. The fourth left costal cartilage near the costochondral junction was found severed in part and there was a laceration of the parietal pleura about three-quarter inch in length in the fourth interspace. The orifice into the pleural cavity was quickly packed with gauze to prevent sucking and the fourth and fifth

costal cartilages together with about two and one-half inches of adjacent rib were removed. A window was then cut in the parietal pleura corresponding to the area of resected ribs. Immediately the lung was grasped with a sponge forceps and held up to the chest wall in order to stabilize the mediastinum. About eighteen ounces of blood were evacuated from the pleural cavity. The pericardium appeared tense and on its lateral aspect there was a hematoma about one and one-quarter inches in diameter. This was apparently the wound of entrance plugged with blood clot. The pericardium was then opened by a three inch longitudinal incision at which time a tremendous gush of blood occurred which spurted over the operating table and down upon the floor. This continued until the heart was drawn forth from the pericardial sac and a suture passed through the heavy muscular apex. The heart was then drawn well into view and by the gentle traction of this suture the bleeding was almost completely controlled. A laceration was found leading into the chamber of the right ventricle as indicated in Fig 2. The wound was about five-eighths inch in length, slightly irregular, and was situated about one-half inch from the anterior descending coronary artery, and about one inch from the auricular-ventricular groove. Two sutures of chromic catgut including the entire wall of the ventricle controlled bleeding from the heart. When the pericardium was emptied of its blood, the anesthetist reported a freely palpable pulse, rapid but of good quality. The traction suture was removed from the apex and the heart was returned to the pericardial sac. The pericardium was not sutured, in order to allow drainage into the pleural cavity, thus preventing heart tamponade from any exudate that might develop in the pericardial sac. The defect in the chest wall produced by the resection of ribs and cartilage was repaired by suturing the lung to the chest wall so that it completely obturated the defect. The muscle-skin flap was then returned and sutured in place and the space beneath it drained by iodoformized gauze.

The blood pressure which was previously zero rose to 110 systolic and ninety-five diastolic. The pulse was regular and of

Fig 1 The C shaped incision was carried down to the ribs. The scar of the wound entrance may be seen as a small dark area within the arc of the incision. Although there exists a fairly large defect in the bony thorax including the parietal pleura there is no herniation of lung and only on coughing is there a slight impact.

Fig 2 Operative defect in the chest wall with resection of ribs and cartilage. The heart is drawn forth by means of a traction suture. The lung, which is held in the wound by means of a sponge forceps, is not shown. The relative size and position of the laceration of the right ventricle is illustrated.

good quality with a rate of 120 beats per minute

Continuous intravenous physiological saline solution was administered. About 3500 cc were given within the first three hours and through the same apparatus a transfusion of 500 c.c. of citrated blood was given before the end of the operation.

Convalescence was extremely stormy. This was apparently due to infection. The tem-

perature was high, and the pulse frequently reached 160 beats per minute. Transfusions of citrated blood were given on alternate days in the first week. Morphine was given at regular intervals to quiet his extreme restlessness and thereby lessen the burden on his heart. He appeared to be getting rapidly worse and on October 26 he appeared moribund. On October 29 a profuse purulent discharge occurred from the wound. The source of this pus, whether from pleura or from pericardium, could not be ascertained. Following this, his condition was greatly improved. He rapidly gained strength, appetite untoward symptoms occurred until December 1, when, although apparently he had been quite well, he suddenly was seized with convulsions, was extremely excited, and then went into a coma. His pupils were dilated. This attack occurred in the evening and the following morning the patient appeared normal again. This seizure, it was later dis-

covered, was due to the surreptitious smoking of a marijuana cigarette. He was kept in the hospital until January 8, principally that he might be observed. At present his condition is excellent and he is symptom free. He has led a vigorous life without any ill effect.

The electrocardiographic changes observed postoperatively by Dr. Martin are of importance. It is interesting to note that in this

case the changes he describes are similar to those of clinical coronary occlusion and to those of experimental occlusion and section. Within two months, however, the abnormal coronary signs returned to normal.

Prior to this successful case, the author operated without success upon four patients with penetrating stab wounds of the heart. Observations in these cases and in those operated upon by other members of the staff may be of interest. Unfortunately, because of the rarity of the condition, it is difficult to gain actual experience in these cases and a reading of the literature alone does not adequately prepare one to perform the operation successfully. One may have to learn certain facts from one's failures.

The usual methods described for approach to the pericardial cavity have proved clumsy, as a rule, in our hands. The usual methods include a flap composed of rib and cartilage and underlying pleura, or an intercostal incision with section of ribs so that they may be retracted in a slung effect. Not only is the approach difficult but closure presents some hard problems. We have found it not easy to make an airtight closure of the pleural cavity after the usual methods of approach.

In all cases, pneumothorax of the left chest, collapse of the lung, and mediastinal shift occur. No provision is made for these complications which reduce the vital capacity. By means of the operation described by the author in cases of penetrating stab wounds of the lung,¹ it has been found possible to close the orifice in the chest wall, reduce the pneumothorax, and prevent mediastinal embarrassment. This is partly illustrated in Fig 3.

"Palming" the heart has been advocated as a method of drawing it forth, controlling hemorrhage by pressure on the large vessels at the base of the heart and steadying the organ so that sutures may be introduced to close the lacerated wound. In our experience traction by means of a suture placed in the thick muscular apex is a far better method. In the former procedure, greater hemorrhage and stoppage of the heart or marked delirium cordis is the rule.

Plugging the hole in the heart with a finger proved, on occasion, a dangerous procedure. In some instances it may con-

trol hemorrhage but in others it may produce a more extensive laceration of cardiac musculature, so large that it may prove too great or irregular to suture securely. The variations in friability of cardiac musculature when manipulated in operation are striking. In general in suturing the heart a fine intestinal needle should be used. The "nontraumatic" type with the suture fastened in the head of the needle is ideal. Large caliber needles may produce holes in the heart muscle big enough to allow for a profuse outpouring of blood and necessitate a separate closure. The sutures should be carefully prepared in advance and placed where the operator may grasp them at the opportune time, for delay at this time may prove costly. The type of suture material to be selected is apparently of no great importance. Silk or catgut may be used provided it is fine and strong. No patient died because sutures were incompetent. We were able to observe that healing of the heart muscle begins early, and in those cases in which death occurred two or more days after operation, repair was uniformly firm.

The internal mammary artery and vein must be sought and ligated. When lacerated these vessels may bleed from either side. In a patient who has lost a large quantity of blood the artery may fail to spurt when thoracic exploration is made. However, when the lacerated heart has been repaired and fluids have been ad-

Fig 3 Means of repairing the defect in the chest wall. Lung is attached by means of a continuous suture interrupted at intervals. This provides for airtight closure of the pleural cavity and fixes the mediastinum.

ministered intravenously, the blood pressure may rise sufficiently to cause bleeding from the severed internal mammary vessels and death. This happened in one of our cases thirty-eight hours after operation.

The preoperative and postoperative intravenous administration of fluids requires careful consideration since the requirement for fluid varies. The cases may be divided into two main groups, (1) those with small loss of blood and (2) those nearly exsanguinated.

Not all cases of penetrating wounds of the heart are brought to the hospital exsanguinated. Occasionally the pericardial wound is rapidly closed after penetration so that only a few ounces of blood escape. The pericardial wound is closed by blood clot which forms in the pleuropericardial wall and closes the aperture very much after the manner of the shutter of a camera. Heart tamponade occurs and further loss of blood is impossible. This occurred in one of our patients. The laceration in the heart was repaired and immediately after the operation the patient seemed to be doing very well. It was not realized, however, that he had lost very little blood, since all our previous cases had come to the hospital almost exsanguinated. Blood and physiological saline solution were given intravenously to the extent of 3500 c.c. within an hour and a half after operation, and the patient died two hours after the operation. Post-mortem examination showed both lungs fully expanded, heavy, firm, and soggy because of diffuse edema apparently due to an overdose of intravenous fluid.

For patients who have lost a great deal of blood, fluids should be given freely by vein after cardiac repair. As much as 2000 to 2500 c.c. of physiological saline solution and 500 to 1000 c.c. of blood may be given within a few hours after the pericardium is opened and fluids may be continued intravenously at the rate of 3000 to 4000 c.c. per day. Transfusions may be

given on alternate days not only to overcome acute anemia but also to combat infection. It seems quite unlikely that even a sudden introduction of a large amount of fluid into the circulation can dislodge sutures in the heart muscle which have been properly placed and tied. The question of tying sutures in systole or diastole has proven in our experience to be purely academic, for practically one does not take notice of the phase of the heart beat.

It has been our practice to leave the laceration in the pericardium unsutured, with the purpose of allowing drainage from the pericardial sac into the pleural cavity. In one case observed by us the pericardium was tightly closed and an exudate occurred into the sac causing symptoms of heart tamponade and severe infection. With the evacuation of the exudate, however, the abnormal symptoms disappeared.

After hemorrhage, the most frequent cause of death is infection, pericarditis, mediastinitis, inflammation of the left pleural cavity, and sepsis. Combating this infection is a difficult task since no specific approach can be made. One should depend upon frequent transfusions and morphine. Morphine is very useful in these cases of infection because the patient exhibits an extreme motor and mental restlessness, thrashing about and attempting to leave the bed. Morphine gives the heart and, indeed, the entire body a much needed rest and allows energy to be used for repair instead of being expended in unnecessary psychomotor activity.

Summary

A case is described of successful suture of a penetrating stab wound of the heart and the surgical lessons learned in this and in other observed cases are presented.

INJECTION OF VARICOSE VEINS DURING PREGNANCY

GOODE R CHEATHAM, M D AND ABEL E PECK, M D , *Endicott*

From the Obstetrical Department of Endicott-Johnson Medical Service and Ideal Hospital

Opposition to treatment of varicose veins of pregnancy is not new In 1579 Ambrose Pare¹ wrote, "Women with child are commonly troubled with them by reason of the heaping together of their suppressed menstrual evacuation It is best not to meddle with such as are inveterate for such being cured there is to be feared a reflux of blood to the noble parts whence there may be danger of malign ulcer, a cancer, madness or suffocation" Pigeaux² warned of a case of abortion in a cook following bandaging of varicose veins

De Lee³ states the dangers of varicosities during pregnancy as ulceration, phlebitis, emboli, and rupture with fatal hemorrhage, then adds under treatment, "Little can be done to cure bad cases of varicosities during pregnancy, but I have helped several cases by the administration of calcium"

Williams⁴ states, "Active treatment is useless in vulval varices but the danger of their rupture at the time of labor should be borne in mind"

This opposition to treatment is clearly illustrated by the fact that during the first nineteen months that we offered the injection method of treatment, we were able to treat only twenty-four cases, although during this period, we had 503 deliveries Either the patients themselves were opposed to treatment or had been advised by other physicians to postpone treatment until after delivery

This delay in applying an accepted method of treatment for nonpregnant patients to pregnant patients is typical of medical progress If we study the history of any medical or surgical advancement, we find that the pregnant woman is the last to receive its benefits For years no one dared do an appendectomy on a pregnant woman More recently the same was true of thyroidectomy, yet no one now hesitates when these procedures are

indicated The injection method of treating varicosities is going through the same process

The history of the injection method of treating varicose veins is too well known to need repeating It is today an accepted procedure The application of this method of treatment to varicosities of pregnancy is not so well-established or accepted hence a brief review of the application of this method of treatment to varicosities of pregnancy is not amiss

In March 1930 De Takats⁵ reported the successful treatment of six cases of varicosities of pregnancy and advocated further investigation and study

In September 1931 Hawk⁶ strongly advocated the injection of varicosities of pregnancy up to the six or seventh month

In October 1931 McPheeters⁷ reported forty-six cases of varicosities of pregnancy injected safely He concluded that it was a perfectly safe procedure and should be done when indicated

In January 1933 Kilbourne⁸ in a general discussion of varicose veins of pregnancy gives no personal experience but in discussing McPheeter's work states that he considers it safe and proper treatment during the fourth to seventh month of pregnancy

In April 1935 we⁹ submitted a preliminary report of twenty-four cases, treated safely This present report includes the entire series and including those twenty-four cases—all cases done from September 1933 to March of this year During this time we had 838 deliveries One of us (C) did the deliveries, the other (P) the injections Complications and results were observed individually and jointly

Before we began our series we reviewed the literature to try and find some real reason why pregnancy was considered a contraindication for injection by

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

many physicians. We found none. Also all the reported fatalities which we found were patients who were confined to bed, therefore, we decided not to inject any patient during the last two weeks of pregnancy, not because of fear of the injection itself but because labor might begin and our patient be confined to bed. We reasoned that if it were safe to inject varices of pregnancy up to the seventh month, it was safe to inject up to term. Likewise if it were safe to inject nonpregnant varices above the knee, and one of us (P) had done many, it was also safe to inject varices of pregnancy above the knee. We have set no limitations on the size or location of the varix or the stage of pregnancy except the last two weeks for reasons previously given. No hyperthyroid, diabetic or cardiac was injected. Only true varices were injected. At first all varices were injected but after doing three superficial unimportant ones, the injections were limited to those varices which were causing pain or discomfort.

The technic was the usual technic of injecting any varicose veins. The deep circulation was always tested. Sodium morrhuate was used exclusively. The average injection was two and one-half to three c.c. The injections were given twice a week. The largest number given any patient was seven. The injections were begun at the ankle and extended upward. No bandage was used following injection and patients were urged to continue their normal routine. No treated patient was hospitalized longer than an untreated patient. As near as possible identical delivery and postpartum routine was used on treated and untreated cases.

Results

The entire series consists of forty-six cases in a series of 838 consecutive deliveries, forty-four were delivered, two undelivered. No treated case failed to be relieved. No treated patient had any postpartum complication of the circulatory system excepting one. One patient had a local reaction before delivery with no untoward results for mother or baby. One patient had postpartum phlebitis of the veins of the untreated leg while the treated leg had no phlebitis. The one patient mentioned above as having post-

partum circulatory complications is open to debate as to what part, if any, the injections had to do with her phlebitis.

This patient at about seven months was given one injection one afternoon and was admitted to the hospital the following morning with lobar pneumonia. She had quite a stormy illness developing empyema, she was operated three weeks after admission. Two weeks following operation she was delivered of a living infant, and was still under the oxygen tent at the time of delivery. Two weeks following delivery, she developed a phlebitis of the injected leg. This leg cleared and was promptly followed by phlebitis of the untreated leg. The lapse of time, seven weeks, from injection to development of phlebitis was so long that we did not feel that the phlebitis was due to the injection.

The case is reported however for we are equally as anxious to note any complications or contraindications to injection as we are to note benefits. One of our primary purposes in starting this series was to try and ascertain if there were any definite contraindications to the injection of varicose veins of pregnancy.

Our conclusions are based on the statements of the patients plus our clinical observation of the results. Each patient on completion of the treatment was asked this question, "If, now that you have had the treatment and know what it is like, you had the choice of keeping the veins or having the treatment, which would you choose?" Three chose the veins, the remainder the treatment.

Based on the patients' statements and our observations, we conclude that the injection of varicose veins of pregnancy is a safe procedure and that it gives relief in the vast majority of cases. This being true, we see no logical reason for postponing treatment until after delivery. Many of these patients were at least partially incapacitated. Why should treatment be withheld when they can be safely relieved by so simple a procedure as venous injection? Certainly in our hands, bandaging, rest, supportive stockings, etc. have been far from satisfactory in relieving the patient, and have accomplished nothing toward a cure.

It has been often said^o that varicosities decrease after delivery and hence should be injected then as a smaller clot will be

required to obliterate the veins. This is true but varicosities of pregnancy rarely, if ever, completely disappear following delivery. They always reappear and are progressively worse at each subsequent pregnancy. The prominence of the veins during pregnancy makes the procedure extremely simple and assures a complete obliteration of minute tributaries which would probably not be reached if done after delivery. It is during pregnancy that the symptoms occur, and after all, most of our patients come to us primarily for the prompt relief of symptoms. If this can be done with safety, they are entitled to relief.

Varicosities of the vulva deserve especial mention. They are far more dangerous than any others. We have had one fatality in our hospital, but not on our service, from the rupture of a varicosity at the time of delivery. These varices are amenable to only surgery or injection. Surgery is a far more complicated procedure requiring hospitalization. The

simplicity of the injection method of treatment and the fact that it is an office procedure strongly recommends it in preference to surgery. Our experience here is too limited for us to do more than give our results. We have injected two cases with bad varices of the vulva, and both were delivered. The veins were obliterated and there were no ill effects. Certainly this is worthy of further trial.

Conclusions

1 The injection method of treatment of varicose veins of pregnancy is a simple, safe procedure which gives better results than other methods of treatment.

2 It should be used during pregnancy in preference to waiting until after delivery.

3 Its use should be restricted to those varicosities which are causing discomfort or pain or those which may endanger the life of the patient at the time of delivery.

Discussion

DR. HAROLD J. SHELLEY, *New York City*—It is true now as in the past that a generally accepted misconception as to the inadvisability of using a certain form of treatment has denied thousands of patients the benefits which would have accrued to those patients had they been allowed to receive what was later found to be a most useful form of treatment. This is the case with the injection treatment of varicose veins during pregnancy. For this reason Drs Cheatham and Peck are to be particularly congratulated for having demonstrated so conclusively by their figures that the injection of varicose veins during pregnancy is a safe procedure and that the results are most satisfactory.

Varicose veins are particularly troublesome during pregnancy. They can be, not only a source of great discomfort to these patients, but, indeed, often a cause of actual disability. Also their presence during and after delivery materially increases the patient's susceptibility to the development of

phlebitis. Therefore patients should be given the benefit of any form of treatment which will safely eradicate these veins during pregnancy. Injections, given by a properly qualified person, will eradicate these veins and will do it in a perfectly safe manner. Relief is obtained from the pain and disability caused by the lack of circulation in the varicose veins and the possibility of a phlebitis developing after delivery is greatly lessened.

For the past ten years I have never hesitated to inject varicose veins during pregnancy whether they cause symptoms or not, and I have never had any untoward results.

If the patients come to me early, I try to have all of the varicose veins obliterated by the end of the seventh month of their pregnancy. If the additional increase in the size of the uterus causes more varicose veins to appear after that time, I inject them, but time the injections so that none will be given closer than ten days to two

weeks before delivery The patients whose veins are being injected must be ambulatory

I have made it a rule never to use a quinine solution for the injections during pregnancy This may be an unnecessary precaution, as it would appear unlikely that the dose used, 0.266 gm of quinine hydrochloride twice a week, could have any action in starting contractions of the uterus

However, Edwards¹ has reported that he had one patient, three months pregnant, who bled after each of two injections of quinine and urethane The injections were discontinued and she went on to a normal completion of her pregnancy

He goes on to state that during pregnancy he injects only those veins giving troublesome symptoms or which appear dangerously near a rupture

For emphasis, I wish to repeat that I am firmly convinced that Doctors Cheatham and Peck have proven their case and that I agree with them heartily when they state

that the injection treatment of varicose veins during pregnancy is a safe procedure and gives good results I might even say that their conclusion is an understatement. I would say the injection of varicose veins should be done in pregnant women both for the relief of symptoms and as a prophylactic measure to prevent phlebitis following delivery

I should like to ask just one question of Drs Cheatham and Peck In the two cases in which they injected varicose veins in the vulva, were the thrombosed veins any hindrance to delivery by decreasing the elasticity of the tissues of the lower end of the birth canal? If not, their injection would certainly be of very great value because we all know the great probability of their rupture during delivery

DR CHEATHAM—The injected varicose veins of the vulva were no hindrance to delivery

"SEVEN DEADLY SINS" OF CONTRACT PRACTICE

The "seven deadly sins" of contract practice of medicine have been listed by Dr Nunzio A Rini, acting chairman of the Kings County Medical Society's economic committee. These offenses against professional ethics he describes in the society's October 1936 bulletin

- 1—Solicitation of patients
- 2—Underbidding to secure a contract
- 3—Inadequate compensation to assure competent service.
- 4—Interference with reasonable competition in a community
- 5—Prevention of free choice of physicians
- 6—Making adequate treatment of patients impossible because of the physician's employment conditions
- 7—Fulfilling a contract which is in any way contrary to sound public policy

Discussing what's wrong with this method, Dr Rini points out

When anything alters the direct personal responsibility, confidence and personal interest between physician and patient, it tends to dilute and weaken the relationship

In private practice, the doctor builds his success upon satisfactorily fulfilling his obligation to the patient In contract practice his success depends more upon his affability and social relations with the employers who pay the bill There is always a breakdown in price which necessitates an overloading of work.

One of the greatest evils associated with the practice is the temptation for dishonesty and collusion between the doctor and patients in some instances, but more often between the employer and the doctor against the patient.

These abuses together with the inadequate compensation and degrading competition go hand in hand And the result is to lower standards of ethical medicine, the quality of medical service rendered deteriorating accordingly

WHEN LETTER WRITING IS DANGEROUS

Georgia doctors have been advised by the attorneys of their State Medical Association not to answer letters containing threats to sue for malpractice The doctor is always tempted in his reply to give a long, detailed account of the case, and to make statements which may cause trouble if the case comes to trial The lawyers know best how to

answer these letters so as to leave no loopholes for future trouble No matter how innocent of neglect a doctor may be, he may so word a letter as to give an opposing lawyer good material for damaging the doctor's case The members are advised to turn threatening letters over to the attorneys or the Committee on Medical Defense

PHYSICAL MEASURES IN PROCTOLOGY

R V GORSCH, M D, *New York City*

We have attempted in this short paper to offer a critical and unbiased review of physical measures in proctologic practice and incidentally to discuss the uses and abuses of electrosurgery, particularly in the surgery of hemorrhoids, and to present some new electrosurgical instruments for proctologic use

Diseases of the Colon

Constipation This subject has been fully dealt with in a recent article by Kovacs,¹ who stresses the importance of differentiating the atonic from the spastic type of constipation and individualizing the treatment. Physical measures—massage, electric muscle stimulation, exercise, diathermy, and water by mouth or rectum—are quite familiar to you

The greatest difficulty in these cases is, of course, the differential diagnosis between an organic and functional type of constipation and it seems pertinent to emphasize here that constipation is frequently enough caused by anal pathology—fissure, obstructive hemorrhoids, sphincter spasm, also by prolapse or intussusception of the sigmoid, adhesions of an inflammatory, postoperative or congenital nature, and finally by malignancy. It is therefore advisable that these patients be carefully proctoscoped and that a complete gastrointestinal x-ray series, and repeated stool examinations for blood and parasites be done before physical measures are used. It is worthy of repetition that the earliest symptom of colonic cancer is a change in bowel habit, and when constipation alternates with diarrhea, malignancy should be most carefully excluded. Less than fifty per cent of the cases of cancer of the colon are already inoperable when the diagnosis is made.

Chronic ulcerative and mucous colitis Many patients with chronic ulcerative and so-called mucous colitis have a neurasthenic background and the importance of psychogenic factors in the etiology and treatment of these serious conditions de-

serve greater consideration. Although of only minor therapeutic importance, abdominal diathermy, static wave current, ultraviolet irradiation, and other selected physical measures might prove useful for the comfort of these patients.

Fever therapy in the treatment of ulcerative colitis is at present under clinical investigation and there appears to be some evidence that it may prove of definite value. However, its exact status must be determined by a closer cooperation between the physiotherapist and proctologist who should check the effects of the treatments by frequent proctoscopic observation.

Tuberculous peritonitis, enteritis, and anorectal tuberculosis The great value of the ultraviolet light in the treatment of selected forms of tuberculosis seems well-established. It reduces the incidence of pain, cramping, diarrhea, nausea and vomiting, stimulates appetite, and prolongs life.

Space does not permit a detailed discussion of its application, however, it may be emphasized again that the therapeutic value of heliotherapy depends almost entirely on its general systemic effects and that local applications of light in tuberculosis is of little value.

The large carbon arc lamps using a current of at least twenty-five amperes seems to be preferred to the mercury vapor lamps.

The proctologist might well avail himself of the therapeutic value of heliotherapy both before and after operative procedures on patients with tuberculous fistulae, coccygeal, and sacral tuberculous involvement, and particularly anorectal tuberculous ulcerations which are notoriously resistant to all forms of therapy. Tuberculous involvement of the intestines and peritoneum should be watched for.

A course of general ultraviolet often has a salutary effect on sluggish perineal wounds and in selected cases, the x-rays may be cautiously used with marked benefit.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

Colon irrigation While colon irrigations were extensively used and widely exploited in the past for many conditions, including constipation, so-called mucous colitis, ulcerative colitis, and auto-intoxication, they are less popular today. There appears too many conflicting views concerning their value from recognized authoritative sources. This is unfortunate, since their use and abuse finds ready con-

From the strictly proctologic standpoint, we believe the value of colon irrigations has been much overrated and their sphere of usefulness is limited to selected cases in which there are manifest signs of obstruction or fecal impaction, or diarrhea with the retention of highly putrefactive products, particularly in the preoperative preparation.

We have been disappointed with the use of colonic irrigations in ulcerative and so-called mucous colitis and the variety of medicated solutions advised are, we believe, erroneously directed against bacteria in the wall of the gut which they can never reach. We employ them now, only in selected cases.

The misleading term high enema, should be abandoned since it provokes the ill-advised and erroneous, and sometimes harmful impression that the higher one inserts the tube, the more effective will be the result.

Diseases of the Anus and Rectum

Pruritus Ani Pruritus ani is still one of the unsolved proctologic problems, and included in the variety of measures advocated for its relief or cure we find several physical measures of which ultraviolet, x-ray, infrared, galvanism, diathermy, and high frequency sparking which have all been used with varying degree of success. All of these physical measures, particularly the ultraviolet light have been of questionable value and the majority of proctologists and dermatologists have not been favorably impressed with these measures. My own experience with the ultraviolet light has been rather disappointing. While the x-ray is frequently advocated for the treatment of pruritus ani, we are decidedly opposed to its use. In the simple cases of pruritus ani, warm wet dressings, hot sitz-baths, rectal lavage after bowel movement, and local

cleanliness are universally applicable and sometimes effective measures of relief.

In the severer types of pruritus, remote etiological factors are involved and it is important to protect both the patient and physician. If physical measures are used, it is essential that remote causative or associated conditions be not overlooked. On several occasions we have made the diagnosis of an unsuspected lues, the only symptom of which was a pruritus ani. This likewise applies to diabetes, tuberculosis, colitis, rectal constipation, malignancy, endocrine disturbances, and particularly the allergic diathesis.

The pruritus ani patient should therefore be handled by the proctologist, at least initially, and bearing in mind the great variety of causative factors, should receive a thorough and comprehensive investigation.

Stricture Medical diathermy if properly used is of considerable benefit in many cases of anorectal stricture, particularly those complicating lymphopathia venerea in colored females. It has undoubtedly saved many of these patients the ordeal of colostomy, has decreased rectal ulceration, discharge, secondary infectious processes, and has alleviated pain and tenesmus.

The important factors in the technique which deserve emphasis are, that an active hyperemia must be produced in the stricture area by prolonged high temperature to the point of tolerance, and that progressively increasing dilatation be carried out when the stricture has softened. The main objection of this form of treatment is that the treatments must be continued at regular intervals for an indefinite period.

The cases should be selected and carcinoma and multiple strictures ruled out by proctoscopy and barium enema.

Strictures of the rectum or sigmoid following x-ray or radium treatment of cervical carcinoma are advisedly not treated by diathermy.

Anal strictures usually respond to surgical treatment, however if this be contraindicated, diathermy may be helpful. Increasing sized metal Pratt dilators make suitable electrodes for the anal canal for the rectum, the simple straight graduated tubular electrodes devised by Frankfeldt are quite satisfactory.

Galvanism has also been used for rectal

stricture It appears to have no advantage over diathermy, particularly the short wave. The same applies to the use of carbon dioxide snow.

Hemorrhoids The application of physical measures in the treatment of hemorrhoids may be palliative or radical and the choice of method depends on the type of hemorrhoids, their clinical activity, the exciting cause, the associated pathology, and the physical status of the patient. It is not sufficiently appreciated that hemorrhoids, particularly the internal variety, are frequently secondary to remote pathological conditions as, cirrhosis, portal congestion, gastric and duodenal ulcer, prolapse of the sigmoid, enteroptosis, uterine and adnexal disease, prostatism, lues, and constipation. Associated cancer of the rectum is still overlooked or not suspected, and the treatment of hemorrhoids, frequently surgical, in about twenty per cent of the patients with palpable or proctoscopically visible cancers of the rectosigmoid speaks for itself.

Any form of treatment in any type of hemorrhoid without a careful sigmoidoscopic examination may be fraught with disaster and no proctologic diagnosis, particularly conditions associated with rectal bleeding, excludes a malignant or premalignant condition of the colon, and it is well to consider cancer until it is definitely ruled out.

Treatment In the early stages of hemorrhoids with no complications, little bleeding, and no prolapse, frequently associated with chronic constipation, medical diathermy may be used with satisfactory palliation. The results probably depend as much on the systematic dilatation as on the heat.

Internal hemorrhoids are occasionally complicated with strangulation, characterized by severe pain, sphincter spasm, edema, thrombosis, and lymphangitis with gangrenous ulceration. This constitutes the so-called attack of piles, and in this acute stage, surgery is advisedly contraindicated. Sepsis and exitus may well follow surgical invasion of a virulent infected field. Medical diathermy and high frequency are of great value in promoting resolution and alleviating pain and spasm in this condition.

The technic of anal diathermy and Oudin application is familiar and will not be discussed. Wet dressings, with some

form of heat and hot sitz-baths are additionally indicated physical measures.

External hemorrhoids are comparatively rare and usually follow labor, longstanding constipation, and portal congestion. Physical measures should be directed to these underlying conditions.

In external thrombotic hemorrhoids, medical diathermy has been used in both the single and multiple types as advised by Kobak who has fully described the technic.² The method is not popular since these small clots are readily removed by simple surgical excision under local infiltration anesthesia of novocain or anacaine. (A corona of multiple thrombi is frequently associated with the attack of piles which should be treated along palliative lines as already advocated.)

Electrosurgical Treatment

Desiccation—In the surgical treatment of hemorrhoids, the desiccating current is usually applied either by direct contact or by successively plunging the electrode tip into the substance of the hemorrhoid. Subsequent drying, shrinkage, and sloughing occurs depending on the strength of the current, the depth of its penetration, and the vascularity of the tissues. The hemorrhoid may also be grasped in a clamp after freeing its base, and the superimposed tissue either completely desiccated or partially excised, and the remaining stump desiccated. This is decidedly the preferable procedure and our observations and experience with electrosurgical technics have convinced us that desiccation over a clamp, combined however with a distal ligature, is the method of choice for those favoring electricity in the surgical treatment of hemorrhoids.

Coagulation—The coagulating current has been greatly abused in the surgery of hemorrhoids. Snare technic with this form of current deserves particular condemnation. Biterminal clamps designed to control the depth of coagulation often fail to do so and should be discarded. There are, moreover, simpler and safer methods of securing the same end result.

Cutting current—There is no place for the cutting current in the surgical treatment of any type of hemorrhoids.

Theoretically, electrosurgical methods would appear to be ideal in the treatment of hemorrhoids but actually, they are decidedly less satisfactory than a clean ligature operation. The vast majority of hemorrhoids requiring surgery are complicated by chronic submucosal infection,

Colon irrigation While colon irrigations were extensively used and widely exploited in the past for many conditions, including constipation, so-called mucous colitis, ulcerative colitis, and autointoxication, they are less popular today. There appears too many conflicting views concerning their value from recognized authoritative sources. This is unfortunate, since their use and abuse finds ready condonation.

From the strictly proctologic standpoint, we believe the value of colon irrigations has been much overrated and their sphere of usefulness is limited to selected cases in which there are manifest signs of obstruction or fecal impaction, or diarrhea with the retention of highly putrefactive products, particularly in the preoperative preparation.

We have been disappointed with the use of colonic irrigations in ulcerative and so-called mucous colitis and the variety of medicated solutions advised are, we believe, erroneously directed against bacteria in the wall of the gut which they can never reach. We employ them now, only in selected cases.

The misleading term high enema, should be abandoned since it provokes the ill-advised and erroneous, and sometimes harmful impression that the higher one inserts the tube, the more effective will be the result.

Diseases of the Anus and Rectum

Pruritus Ani Pruritus ani is still one of the unsolved proctologic problems, and included in the variety of measures advocated for its relief or cure we find several physical measures of which ultraviolet, x-ray, infrared, galvanism, diathermy, and high frequency sparking which have all been used with varying degree of success. All of these physical measures, particularly the ultraviolet light have been of questionable value and the majority of proctologists and dermatologists have not been favorably impressed with these measures. My own experience with the ultraviolet light has been rather disappointing. While the x-ray is frequently advocated for the treatment of pruritus ani, we are decidedly opposed to its use.

In the simple cases of pruritus ani warm wet dressings, hot sitz-baths, rectal lavage after bowel movement, and local

cleanliness are universally applicable and sometimes effective measures of relief.

In the severer types of pruritus, remote etiological factors are involved and it is important to protect both the patient and physician. If physical measures are used, it is essential that remote causative or associated conditions be not overlooked. On several occasions we have made the diagnosis of an unsuspected lues, the only symptom of which was a pruritus ani. This likewise applies to diabetes, tuberculosis, colitis, rectal constipation, malignancy, endocrine disturbances, and particularly the allergic diathesis.

The pruritus ani patient should therefore be handled by the proctologist, at least initially, and bearing in mind the great variety of causative factors, should receive a thorough and comprehensive investigation.

Stricture Medical diathermy if properly used is of considerable benefit in many cases of anorectal stricture, particularly those complicating lymphopathia venerea in colored females. It has undoubtedly saved many of these patients the ordeal of colostomy, has decreased rectal ulceration, discharge, secondary infectious processes, and has alleviated pain and tenesmus.

The important factors in the technic which deserve emphasis are, that an active hyperemia must be produced in the strictured area by prolonged high temperature to the point of tolerance, and that progressively increasing dilatation be carried out when the stricture has softened. The main objection of this form of treatment is that the treatments must be continued at regular intervals for an indefinite period.

The cases should be selected and carcinoma and multiple strictures ruled out by proctoscopy and barium enema.

Strictures of the rectum or sigmoid following x-ray or radium treatment of cervical carcinoma are advisedly not treated by diathermy.

Anal strictures usually respond to surgical treatment; however if this be contraindicated, diathermy may be helpful. Increasing sized metal Pratt dilators make suitable electrodes for the anal canal for the rectum, the simple straight graduated tubular electrodes devised by Frankfeldt are quite satisfactory.

Galvanism has also been used for rectal

rectum is not fully understood. These functional aberrations are characterized by sensory disturbances of which attacks of pain, spasm, burning, itching, irritability, etc. are common complaints.

Several of these intractable cases follow rectal surgery in which excessive scarring persists in the anal canal. Reflex possibilities and psychogenic factors are important. It is frequently impossible to assign any causative demonstrable pathology, but organic pathology must be carefully ruled out and psychopathic examinations are advisable.

It would seem that physical measures should be of great value in these intractable cases and this is not sufficiently appreciated. Surgery usually aggravates their condition.

Rectal diathermy, abdominorectal, abdominovaginal or transpelvic diathermy may be used. For the psychic element, cabinet electric baths, ultraviolet radiation, static wave, and galvanic baths are useful in various combinations, sometimes with marked improvement.

Gonorrheal proctitis. Rectal gonorrhea is much more frequently associated with a genital infection of gonorrhea than is usually suspected. Fever therapy seems destined to play a very important part in the therapy of gonorrheal infections. Desjardins and his coworkers,⁴ who have had considerable experience in fever

therapy state that with improved methods, ninety to ninety-five per cent of patients can be cured of this noteworthy chronic infection. It appears that fever therapy will eventually supplant the instrumental methods with their complications. It is worthy of emphasis that a rectal gonorrheal cryptitis, may be an important focus for a most protracted gonorrheal arthritis. Fever therapy should be of particular value in these cases.

Summary

All the specialties are a part of medical practice. The proper status of physical measures in proctologic practice must eventually evolve from a closer cooperation of physiotherapist and proctologist who at present has assumed a quiescent attitude toward physical measures. Electrosurgery is much used and much abused by both physiotherapist and proctologist. We have attempted to emphasize some of its indications and contraindications in proctologic practice and to place it on a firmer scientific basis.

Discussion

DR. F. LESLIE SULLIVAN, *Scotia*—Dr. Gorsch has given us a very comprehensive and complete survey of physical measures used in proctology. I may offer this conclusion however, that the use of physical measures is the exception rather than the rule. I do not believe that the majority of proctologists deliberately neglect them but rather have found that their inadequacy in many conditions deny their use. In many instances, however, inaccurate knowledge of management of physiotherapeutic details cause their improper application and subsequent failure.

In chronic constipation, the value of exercise for the abdominal muscles, massage, the use of fluids by mouth and rectum are well-known, provided of course, that the cause is entirely functional. It is a well-known fact that all too often the physician has advised physical measures in the presence of a carcinoma of the colon or some other pathological condition. All organic

conditions must be first ruled out by a careful history, procto-sigmoidoscopic and fluoroscopic examinations.

Concerning bowel function, I cannot too highly evaluate a thorough fluoroscopic examination which will give the proctologist a mental picture of the function of the bowel in question, as well as rule out any organic condition.

At the Ellis Hospital (Schenectady) cases of unstable, irritable or spastic colon are treated by bowel management. We remove, as much as possible all environmental factors and give the patient mental and physical rest. They are put to bed and given a non-roughage diet. We avoid enemas of any nature and encourage the patient to establish a habit of daily bowel movement. The only fluids used are, at times a little warm olive-oil in the rectum or retention of three or four ounces of warm water, or, these failing, a pint of water into the area of defecation, slowly.

sphincter spasm, fissures, large skin tags, infected crypts, enlarged papillae, and prolapsing mucosa. Removal of these pathological changes with proper drainage frequently constitutes the more important part of the hemorrhoidectomy. We are decidedly opposed to the so-called office or ambulatory hemorrhoidectomy. If electro-surgical methods are used, the cases should be carefully selected, and at best, they are suitable only for the uncomplicated case of internal hemorrhoids.

Galvanism in hemorrhoids—The galvanic current which supposedly produces an electrochemical caustic action in the hemorrhoid has been used for many years. We have had but little experience with galvanism and have long since discarded it because of the number of uncontrollable and variable factors in the technic, further, because it is only applicable to a selected group of uncomplicated cases of surgical hemorrhoids. The time consumed, the necessity for an exact placing of the needle electrode, the duration of the individual treatments, the exact milliamperage, the extent of the caustic reaction—are all arbitrary and variable factors. Furthermore one must appreciate that many hemorrhoids have a considerable degree of interstitial fibrous changes and it would seem quite difficult to determine the exact point to which the destructive action of this current should be carried. One must further appreciate that it produces a necrosis of tissue in an already infected field and its results depend on a slough of tissue which is not predictable within safe limits.

The injection treatment with its limitations, requiring no special apparatus and with better controlled factors is a safer and preferable nonsurgical method.

Among other physical measures, the use of radium or x-ray in the treatment of hemorrhoids is an entirely irrational and dangerous procedure. It marks the height of fadism in an already variegated treatment of hemorrhoids.

Fissure in ano Simple uncomplicated fissures may be treated by diathermy. Relief sometimes follows the complete desiccation of the surface of the fissure with the Oudin current. Coagulation should never be used. The method requires complete anesthesia and dilatation for free drainage and sphincter rest which are essential in the aftercare. In the radical treatment of fissure, if the sphincter muscles are divided the incisions are preferably made with the cold scalpel, since

muscle tissue almost fades away under the electric knife.

Fistula in ano Physical measures play a minor role in anorectal fistula. Ionic medication has been used but is of questionable value. The x-ray has been highly recommended by Bensaude⁸ of Paris. In extensive fistulae with multiple openings, it may perhaps be of some value. We have had no experience with the x-rays in fistula and the method does not appear to be very popular in the United States. It has obvious limitations around the genitalia.

In the surgical treatment the cutting current would theoretically appear to offer decided advantages in the excision or incision of fistulae. However, in our experience, the electrified knife cuts with such rapidity that it is difficult to judge whether one is cutting through diseased or normal tissue, a most important consideration for good fistula surgery. We still find the scalpel the most sensitive effective weapon for this type of surgery. Moreover the dissection of tracts close to the rectal wall with the cutting current is done with considerable risk of immediate and remote perforation. The actual cautery is preferred by some in the tuberculous variety of fistula when this can be determined beforehand.

Coccygodynia The exact etiological basis for this condition is not always clear. The majority of cases fall into a traumatic and nontraumatic group, frequently on a neurogenic basis. The traumatic group may be greatly benefitted by rectoabdominal, rectosacral or transpelvic diathermy as indicated.

The nontraumatic group are more often benefitted by the injection of alcohol or anucaine, which also is a sort of therapeutic test for definitely reflex pathways.

Surgery is frequently disappointing and it should be preferably used only after a thorough trial of diathermy and other physical measures.

Neuralgia, hysteria of the rectum, etc (Rectal phobia, sphincteralgia, sphincterismus, and anal cramp). This collection of terms refers to a group of ill-defined conditions, usually functional, which manifest themselves primarily through the neuromuscular apparatus of the anorectal region. They are not all well-understood, in fact, the innervation of the anus and

cautery, the fulgurating snare, dessication, and coagulation have their place and are of great value if used by operators acquainted with their use. The use of galvanism or ionization, electrocoagulation or electrodesiccation I believe have no value in the treatment of hemorrhoids. The operation for cure of hemorrhoids is perfectly simple and need not be greatly elaborated. The simple fixation and ligation operation in our hands has served all purposes, with a comfortable, thankful patient.

We have found that coagulation and fulgeration is of great value in inoperable malignancies of the rectum and sigmoid. It is a palliative measure and may be used at the time of introduction of gold wire or of platinum filtered radium seeds. Very frequently care of this nature under trained hands will keep a patient comfortable, free from obstruction, and alive for several years.

Two years ago at a New York institute, I examined an elderly man who had a low-lying inoperable malignancy. He was treated with radium at that time and once since. On various occasions the growth was coagulated. I was agreeably surprised when I saw him two weeks ago looking quite well. He had lost very little weight, had had no bleeding, and very little pain. This man will succumb eventually to this second greatest cause of death but due to these physical measures the interval of his life's span has been lengthened, and made more comfortable and more happy.

DR. JOHN C. M. BRUST, *Syracuse*—It has been a real pleasure for me to hear Dr. Gorsch, and particularly so, since he has wisely adopted a very conservative attitude. It is probable that no portion of the anatomy of the American public has been more grossly exploited by charlatans than the lower large bowel and rectum.

With increasing knowledge of the usefulness of physical therapeutic measures, certain diseased conditions requiring the care of a proctologist may be treated in a more conservative manner. I refer particularly to adenomatous polyps of the sigmoid and rectum. As you well know, many, if not most of these adenomas, appear benign when viewed through a sigmoidoscope. They may be pedunculated or sessile, they vary greatly in size, color, and shape, they may or may not produce symptoms. Yet, certain facts stand out most alarmingly to one who has exhaustively studied the histologic pathology of these supposedly benign growths. If one carefully sections a large

series of these adenomas, small areas of early and low grade malignancy will frequently be discovered. When seen, thus metaplasia or early frank adenocarcinoma will almost always be toward the periphery of the polyp.

With such facts in mind we can do little else but strongly urge the destruction or removal of such growths. I know of no safer, more complete or more economical method than by the use of electrofulguration through a sigmoidoscope. It is painless and no anesthesia is needed. Bleeding is rare and can be quickly controlled by "retouching" the bleeding point with the fulgurating spark. One should of course be dexterous with the sigmoidoscope itself. It is probably best to begin the fulguration at the tip of the polyp rather than through the base or pedicle. By so doing, the peripheral malignancy if present will be destroyed immediately and bleeding is less likely to occur.

Of course when the growth is located above the line of peritoneal reflection more care is needed in applying the electrode. It is frequently advisable to destroy such high growths in stages.

This field of therapy has been recently encouraged by the work of Strauss of Chicago who is attacking outright carcinomas by fulguration. It is possible to criticize such conservative methods in a malignant lesion which is felt to require most radical extirpation. His figures are encouraging however, and I have no doubt that a new avenue of attack on malignancy of the rectum has been opened up.

I have within the past year treated three patients of middle age who had developed rather extensive though localized areas of polyposis within the rectum. Two of these persons are completely free of any rectal polyps at the present time and one is still being fulgurated two or three times weekly. I am happy that I have saved them from colostomy and a serious surgical operation with its attending high mortality.

DR. HANS J. BEHREND, *New York City*—May I use this opportunity to mention a physical measure of postoperative treatment of hemorrhoids which has become routine in the Hospital for Joint Diseases on the service of the Proctologist Dr. Harry Goldman. It has been a great problem to relieve the anal spasm and edema which develop after the operation. Hot compresses and the sitz-bath were previously used. As in my experience the soothing and healing effect of the steam jet in treating chronic and indolent ulcers has been conclusively demonstrated, I suggested its use for the postoperative management of hemorrhoids.

introduced, and held as long as possible. Other medications are given appropriate to the patient.

There are many and conflicting opinions as to the value of the colon irrigation or lavage. Barger and many other experts in this field of work believe that colon irrigations are contraindicated in mucous colitis and ulcerative colitis. While Bastedo states that colonic irrigations are indicated "in chronic states of the bowel, such as are encountered in 'mucous colitis,' intestinal putrefactive toxemia, and in cases in which a focus of infection is believed to reside in the bowel, as in certain cases of rheumatism, neuritis, secondary anemia, and sundry run-down conditions."

This field of work has been greatly exploited by charlatans, quacks, and lay people, and in many cases, unfortunately, men in our profession. The irrigation of the bowel, as has been frequently done, should not be a matter of routine administration but should be used in *selected* cases only for a definite purpose.

The saline wash either as a rectal wash or cleansing enema has a definite place in therapeutic procedure. It is valuable in cases of edema of the bowel associated with mucous colitis. It is valuable as a cleansing agent. In cases of pruritis and due to mucoid rectal discharge, with or without fecal retention, it is helpful as a rectal wash. It should be used as a normal 8 solution or in cases of edema and diarrhea in mucous colitis as a hypertonic solution. Irrigations *per se* have been used in many and varied ways. Lockhart-Mummery believes that in chronic ulcerative colitis an appendectomy should be performed early and washing started immediately. This is done through a catheter held in the appendectomy with a rectal tube in place. I agree with Cattell that in the *majority* of cases of purulent colitis, a thorough washing with an enema can be done through the rectum and is sufficient as an irrigation.

The use of diathermy in lymphopathic strictures associated with ulceration is beneficial. In simple inflammatory strictures of the rectum of longstanding, diathermy is of questionable value, unless the stricture is associated with ulceration. The use of a Hegar uterine dilator, sizes eight to twenty-five, frequently gives these cases good function. If associated with tenesmus and straining, ulceration bleeding and backache, a colostomy may mean the only relief. Internal proctotomy by cutting current in mid-rectal or high-rectal strictures is always a delicate procedure. I

prefer using a knife in these locations to better avoid hemorrhage due to slough or rapid cutting.

While on the subject of dilators, I might add this. I formerly used dilators following the excision of fissures according to Gabriel's technic, but have discontinued their use because I believe that the continual irritation of a healing field gives a fibroplastic exudate which gives in turn a hard scar. This in itself is easily cracked giving a recurrence of the original trouble. Without the use of a dilator, I believe that we get a more elastic scar with less aptness to recurrence.

In hemorrhoids in the acute stage, dilation, reduction, wet dressing, and hot sitz-baths are the proper procedure—to be followed by surgical removal in the chronic stage. Diathermy, etc., are palliative measures which may give some relief to the cases who wish to avoid surgery or injection, provided these are not cases of late 2° internal or 3° internal hemorrhoids.

In anorectal neuroses, granted that the diagnosis has been definitely established, physiotherapy as a psychotherapeutic agent plays an important part. Here, as in other forms of neuroses, environmental conditions are a large factor and treatment must be directed toward the removal of all external and constitutional causes.

In gonorrheal proctitis, many cases may be cured by properly instituted care—cleansing douches, two or three times daily with medicated solutions, and the careful inspection and treatment of the rectum and anorectal region about every five days in the office. Fever therapy has enjoyed a great popularity in proctitis as well as urethritis but I believe that the above will clear up most cases if thorough. Many cases of gonorrheal proctitis become chronic due to a gonorrheal cryptitis. I have followed the technic of Curtice Rosser in this respect with good results. In cases with continued discharge, most of the pathology will be found in the anal valves. If the cover of the crypt is lifted and gently irrigated by means of a specially adapted crypt irrigator with a mild solution of silver nitrate, most of these will be cured.

Fever therapy has been given a very thorough trial at the Ellis Hospital in conjunction with the Research Department of the General Electric Company and the following conclusion reached that it is of great benefit in gonorrheal arthritis and paresis. It may be of great value in gonorrheal proctitis.

Electrosurgery has a definite and valuable place in proctology. The use of the

PRESENT STATUS AND TECHNIC OF TUBERCULIN TESTING

JOHN KENNETH DEEGAN, M D, *Albany*

State Department of Health

In the past, the numerous methods of administering tuberculin tests coupled with the employment of tuberculins of varying potency, precluded accurate comparison of results obtained in different sections of the country. After much experimentation, it was agreed that the Mantoux technic of employing tuberculin is to be preferred above other methods, in that it permits the use of a known quantity of tuberculin. However, it was not until 1932 that the inherent difficulties of preparing a standard tuberculin of known potency were overcome. In that year, Seibert and Munday¹ described a most satisfactory and practical method for isolating the active principle responsible for the tuberculin skin reaction. The discovery of this substance filled the long-felt need for a standard tuberculin and provided a uniform measuring rod for evaluating results of tuberculin testing programs.

The essential steps leading to the preparation of this principle² are

- 1 Growth of tubercle bacilli on a protein free synthetic medium
- 2 Preparation of old tuberculin from this synthetic medium (SOT)
- 3 Concentration and removal of impurities from this synthetic old tuberculin (SOT)
- 4 Precipitation of the active principle, purified protein derivative, (PPD) by trichloroacetic acid
- 5 Removal of the acid with ether, resulting in a simultaneous dehydration of the protein derivative to powdered form

Commercially, PPD is dispensed in sterile lactose tablets of varying strengths, with suitable amounts of a special sterile diluting fluid in which to dissolve them. Dilutions of PPD have the advantage over OT dilutions, in that they are free of non-specific proteins and salts.

The National Tuberculosis Association has recommended that PPD be used in a two dose technic.³ Employing the Mantoux method, 0.1 c.c. of solution contain-

ing 0.0002 mgm PPD is injected as an initial dose. The test is read forty-eight hours later and nonreactors to the initial dose are injected with 0.1 c.c. of solution containing 0.05 mgm of PPD which is two hundred fifty times as strong as the initial dose. The two dose technic is inconvenient for the patient and the physician but no satisfactory dilution of PPD has as yet been determined which will meet all the requirements for a single dose method.

Itinerant chest clinics of the New York State Department of Health, Division of Tuberculosis, are operated throughout upstate New York, and visit communities for brief stays, usually one day. Because of the limited time in which the clinic remained in any community, it was felt that a two dose technic of PPD could not be employed routinely. Accordingly, discussions were entered into with Doctors Long and Siebert of the Phipps Institute regarding the feasibility of employing a one dose technic for PPD testing. It was agreed that a study of this type would be worth while, and arrangements were made so that all those who requested the test would be given 0.01 mgm of PPD by the Mantoux technic, i.e., one-fifth of the regular second dose. It was felt that this dilution was of sufficient strength to elicit a positive response in all but five per cent of possible reactors. The dilution was freshly prepared twenty minutes before each clinic, by dissolving one standard second dose tablet of PPD in five c.c. of diluent. The reactions were read at the end of forty-eight hours by clinic physicians who had administered the test.

The system of grading the reactions was that recommended in "Diagnostic Aids"⁴ by the National Tuberculosis Association.

A positive reaction is one which shows edema and redness at the end of forty-eight hours. If there is no edema, the reaction is regarded as negative. Reactions

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

The steam jet is an apparatus in which steam at a suitable temperature flows from a nozzle of a movable hose. The usual pressure of the steam is about three or four pounds and the temperature at the skin has been measured to be about 102° F. After the first treatment of fifteen to twenty minutes on the first postoperative day, the patient felt immediate relief. The edema rapidly diminished during the treatment and was considerably relieved after it. The

spasm also was greatly lessened. The patient received one to two treatments daily.

We have treated nine cases so far without failure, and suggest this method not only for the effects mentioned above but because it was also observed that under this treatment, the use of narcotics could be greatly reduced. Another extremely desirable result which we observed was the ease with which the patient was able to void

SPATTERING THE FOE WITH DISEASE GERMS

Among other pleasant and playful plans in pickle for the "next war" is the reported scheme to rain disease germs down in a ghastly shower on enemy cities. Biological laboratories are to work in day and night shifts filling bottles with bacilli that will cause men, women and little babies to expire in agony.

Right here, however, arises the question whether the hail of germs will come up to expectations. Will the much-touted bacilli do the job as advertised? Perhaps not, it appears. Theoretically, writes the Belgian correspondent of the *Medical Record*, there seems to be no reason why any epidemic may not be started with a large supply of virulent germs. However, practice does not seem to follow in theory's wake. When the civilized world was frightened enough by these germ-war rumors, the League of Nations thought it best to ask the advice on this subject of the most outstanding scientists whose authority in this matter is paramount. Accordingly, Bordet of Brussels University, Pfeiffer of Breslau, Cannon of Harvard University, and Madsen of Copenhagen were charged by the Geneva body to investigate and report upon the possibilities of germs as war weapons. After a long study, and after numerous conferences, investigations, and most scientific research, this "Germ-War-Committee" presented a report whose conclusions are condensed as follows by *Minerva Medica*:

1 No definite statement can be made regarding the effects of germs as a war weapon in any given locality, as changing factors may influence such effects.

2 The use of cultures of typhoid fever and Asiatic cholera germs can easily be made harmless by filtration or boiling of all drinking waters.

3 The spread of bubonic plague by means of rats is dangerous, not only for the attacked but for the attacker as well, moreover, plague epidemics can be controlled and localized.

4 The danger of spreading exanthematous typhus by means of lice infected with Rickettsia

prowazeki is much exaggerated, the most elementary rules of hygiene will easily eliminate the disease.

5 No attacker can reckon on the effectivity of germs as a weapon, as our knowledge of preventive medicine and microbiology are advanced enough to enable us to limit the extension of the infection.

The report does not deny the possibility of a germ war, but stresses the fact that once started, such a war can be controlled. It is agreed in all medical circles that hygiene and preventive measures have taught us enough to know how to handle any epidemic, no matter where started.

Not all germs are suited for warfare. Only such germs as will produce general septicemias and toxemias have been placed on the list as "enemy number one." The plague germ has been considered as suitable because it resists well desiccation and humidity, it can be kept alive a long time, is active, easily cultured, and virulent. On the other hand, modern sanitary history shows that whenever a plague epidemic broke out, it was soon stopped.

No doubt the most-to-be-feared germs are those producing the so-called tropical diseases, but the war lords are rather handicapped in this respect, as these germs act, comparatively speaking, slowly, and "tempo," "speed," "surprise," are watch words in modern warfare. Besides, the white man is immune to some of these fevers, while most of these germs require a specific climate with a suitable milieu.

Another question which has not yet been answered fully is the following: Is the laboratory-raised germ as active as the one developed in the animal body? Even Pasteur had his doubts in this matter.

If it be admitted that many laboratories in the world concentrate on plans and means for a future germ war, it must also stand out clearly that many more laboratories, and many more workers are producing means for fighting such diseases.

primary tuberculous infection, which apparently at the time of examination was of no clinical significance

3 Healed primary tuberculosis Those individuals with negative physical findings, who on x-ray revealed calcification either in the parenchyma of the lungs, the draining lymph nodes, or both

There were 269 individuals who revealed x-ray evidence of tuberculous infection of various degrees of significance, as follows

1 Thirty-two active cases of pulmonary tuberculosis, thirty-one of whom reacted positively

2 Six cases of healed tuberculosis, all of whom reacted positively

3 231 cases of healed primary tuberculosis, 221 of whom reacted positively

The failure of one clinical case of tuberculosis and ten cases of healed primary tuberculosis to react positively to the test, is not explained. The opportunity to retest these individuals did not present itself and we are unable to state whether failure to react was due to errors of technic or energy. It is significant however, that 95.9 per cent of the patients showing evidence of tuberculous infection reacted positively to the

TABLE III—ANALYSIS OF INDIVIDUALS WITH ABNORMAL X-RAY FINDINGS ACCORDING TO PPD REACTION, AGE, CONTACT STATUS, AND DIAGNOSIS

CHART I—PERCENTAGE REACTING TO PPD BY CONTACT AND AGE GROUP (STATE CLINIC-1935)

New York State Dept. of Health Div. of Tuberculosis, E.B.B.

test, and that of the 3,029 individuals tested, in only one instance did the test fail to detect the presence of infection of clinical significance, i.e., the case of pulmonary tuberculosis which did not react

There were nineteen cases of clinical tuberculosis discovered in the contact group and thirteen discovered in the non-contact group. The cases of healed tuberculosis in the contact group outnumbered those in the noncontact group 5:1. Of those showing evidence of healed primary tuberculosis, 79.7 per cent were found in the contact group.

TABLE IV—REACTIONS IN CASES OF PULMONARY TUBERCULOSIS

	Total	Minimal	Mod	Adv	Far Adv
Negative	1	0	1	0	0
One plus	7	2	3	2	0
Two plus	12	11	0	1	0
Three plus	9	8	1	0	0
Four plus	3	2	0	1	0

are arbitrarily graded from one (+) to four (++++) plus

A + reaction is one with slight but definite edema (not more than ten mm raised about one mm), the area of redness, which is less important, is usually larger

A ++ reaction is one with well-defined edema (ten to fifteen mm. across, raised somewhat more than one mm) and an area of redness which is usually larger than the area of edema

A +++ reaction is one with extensive edema (measuring more than fifteen mm and raised more than two mm) with a wide area of redness, but with no necrosis of the skin. Redness in a few instances extends along a lymphatic

TABLE I

Patients examined	3,029
Males examined	1,410
Females examined	1,619
Positive reactors (48.9%)	1,480
Positive reactors, males (48.8%)	688
Positive reactors, females (49%)	792

TABLE II

	History of contact	No history of contact
Individuals tested	1,793	1,236
Individuals reacting	1,115 (62.2%)	365 (29.5%)
Negative reactors	678 (37.8%)	871 (70.5%)
1 + reactors	286 (15.9%)	125 (10.1%)
2 + reactors	389 (21.7%)	136 (11.0%)
3 + reactors	391 (16.2%)	68 (5.5%)
4 + reactors	149 (8.3%)	36 (2.9%)

A ++++ reaction is a reaction characterized by extensive edema, redness and a spot of necrosis. It may be associated with elevation of temperature and malaise

In addition to the tuberculin test, each clinic patient had a careful history taken, followed by a physical examination of the chest and a single roentgenogram thereof

There were 3,029 individuals tested by this one dose technic (Table I). Females predominated slightly, 1,619 to 1,410, a total of 1,480 patients (48.9%) reacted positively, i.e., 48.8% of the males (688) and forty-nine per cent of the females (792). The high percentage of positive reactors can be explained by the fact that most of the patients were examined because of a history of contact with a known case of tuberculosis or had been referred by local physicians because of symptoms referable to the chest.

Analyzing the group on the basis of contact with a known case of tuberculosis

it is found, that 1,793 individuals had had such contact and 1,236 had had no known contact. There were 801 males and 992 females in the contact group, while the non-contact group was composed of 609 males and 627 females. The ages range from one year to seventy-two years, the majority (92.9%) of the individuals being less than thirty-five years of age.

In the contact group, 1,115 individuals (62.19%) reacted positively. Table II presents a study of this group by degree of reaction. There were 149 individuals with 4+ reactions, i.e., 8.3 per cent of all contacts or 13.36 per cent of all reactors in the contact group. There were no significant differences observed in the incidence of reactions obtained in the males (63%) and the females (61.5%) of the contact group.

In the group having no history of contact, 365 individuals (29.5%) reacted positively. The analysis of the positive reactors in the non-contact group reveals that 9.86% of the positive reactors gave 4+ reactions. As with the contacts, there were no significant differences observed in the incidence of reactions obtained in the males (30.05%) and the females (29.03%) of this group.

When the reactors of the contact and noncontact group are studied by age it is found, that the contact group presents a much higher incidence in each age subdivision studied (Chart I). The resulting infection with the tubercle bacillus incident to exposure to known cases of tuberculosis is evident throughout the contact group, beginning with the high percentage of reactors (33.9%) in the 0-4 age period, and increasing steadily in the succeeding age groups, reaching a percentage of 76.47 in the 25-34 age period.

We were particularly interested in studying the incidence and severity of reactions in those individuals who presented evidence of tuberculosis. These patients in whom a diagnosis of tuberculosis was made, fall into three groups (Table III).

1 *Pulmonary tuberculosis* Individuals who on x-ray, with or without laboratory or physical findings, showed evidence of pulmonary disease of clinical import.

2 *Healed tuberculosis* Individuals who from x-ray, history, and physical examination, revealed evidence of a healed post-

Discussion

DR. EUGENE W. BOGARDUS, *White Plains*—We can all agree that the Mantoux test is the accepted method of tuberculin testing. We can also agree that tuberculin PPD is the best agent to use. Tuberculin PPD is a standard product of known strength giving accurate readings and a moderate skin reaction. The only disadvantages are the necessity of using two doses and the expense when used on small groups. Dr. Deegan has given us an interesting description of the findings of over three thousand tuberculin tests made on persons of all ages in the New York State Health Department Clinic Service. No information has been given, however, as to the relative distribution of these individuals in the various age groups, except to note that ninety-two per cent of them are under thirty-five years of age. The material would be more useful if we knew what age groups constituted the bulk of the cases. It would also be interesting to know in what age groups the active cases of pulmonary tuberculosis were found.

Concerning the degree of tuberculin reaction, it has been our experience as well as that of others that tuberculin reactions in positive cases have no relationship to the activity of the disease. However, we have observed two facts in regard to tuberculin positive but otherwise healthy children. *First*, that 4+ reactions are more apt to occur in rural groups. *Second*, that a 4+ reaction in a healthy child means recent exposure to tubercle bacilli. In our rural groups we have found a number of cases with 4+ tuberculin reaction and no apparent source of infection in the family. Investigation of the milk supply of these families revealed a number who were using raw milk. A check of the herds from which the milk supply was derived revealed bovine tuberculosis. We believe that it is worthwhile to investigate the milk supply where we have 4+ tuberculin reactions in children with no apparent source of human infection.

Concerning the dosage of tuberculin used, we have used 1/10 milligram of old tuberculin for the initial dose followed by one milligram if the first dose is negative. Our use of tuberculin PPD has followed the directions furnished by the National Tuberculosis Association. However, we have recently been experimenting with a dose one half as strong as that used by Dr. Deegan. We make up the solution by dissolving one of the second dose tablets in ten c.c. of diluent. In all cases where contact is known to exist in the home, we use

a smaller dose for the initial dose. In approximately ten thousand tuberculin tests which have been made, we have had no difficulty with positive reactions.

Dr. Deegan states in his survey that 50 per cent more cases of pulmonary tuberculosis were found in contacts than in non-contacts. If we analyse his figures however, it is apparent that he examined fifty per cent more contacts than noncontacts. Placing the contact group against the noncontact group and comparing the number of cases of tuberculosis found in each group, we arrive at these figures: 1793 contacts yield nineteen cases of tuberculosis or 1.06 per cent, 1232 noncontacts yield thirteen cases of tuberculosis or 1.05 per cent which is almost exactly the same incidence of tuberculosis as that of the contact group. Dr. Deegan states that 48.5 per cent of his contact group reacted positively to tuberculin whereas only twenty-nine per cent of the noncontact group reacted to tuberculin. If we apply the rate of tuberculosis and the rate of tuberculin reaction to groups of one thousand contacts and one thousand noncontacts we would get the following expectation of result. One thousand contacts would yield 485 reactors among whom would be ten cases of pulmonary tuberculosis, one thousand noncontacts would yield 290 tuberculin reactions among whom would be ten cases of pulmonary tuberculosis. If we were to proceed in a group of this size with the usual method of x-raying only the positive reactors, we would find the same amount of tuberculosis in a noncontact group at one half the expense of examining a contact group.

There is one point in dealing with the active pulmonary cases which must be borne in mind. Four of the cases listed by Dr. Deegan are under ten years of age. It is stated that a diagnosis was made after one tuberculin test, one physical examination, and one x-ray. It has been our experience that a diagnosis of pulmonary tuberculosis in a child under fifteen years of age cannot be made without further study. Many lesions prove to be shadows due to nontuberculous respiratory disease or to primary tuberculous infection. In our clinic service, we have found but one case of pulmonary tuberculosis in a child under fifteen.

The cases which Dr. Deegan classified as healed pulmonary tuberculosis are too small in both the noncontact and contact group to permit comparative analysis.

An interesting notation regarding the childhood lesions discovered is that while the childhood infections predominate in

The degrees of reaction obtained in the positive cases of pulmonary tuberculosis are indicated in Table IV

Discussion

The tuberculin test is a potent aid in the study of the epidemiology of tuberculosis. Its major role is that of a "screen" in surveys of groups of individuals, the nonreactors to the test being regarded as free of tuberculous infection. Too often our efforts in surveys of this sort stop with x-raying the chests of the reactors and no attempt is made to determine the source of the infection. It is particularly important from an epidemiological standpoint, that the sources of infection be discovered, the contact broken, and the source case be afforded the benefits of treatment. Few, if any, tuberculin surveys should be attempted unless sufficient funds and personnel are available to investigate the contacts of the positive reactors. The younger the age of the reactor, the more important it is to determine the source of the infection. Should funds not be available for this follow-up procedure for the entire group to be studied, the scope of the effort should be limited in order that worth-while results might be obtained in the homes of the reactors. As a result of careful analyses, we are coming to regard tuberculosis as a disease which is frequently endemic in certain families rather than a scourge of the entire community.⁷

The appeal of tuberculin testing programs in schools can be attributed to the desire of the populace to protect the children from disease. This method usually results in the discovery of less than one per cent of clinical tuberculosis⁶ and proves to be an expensive method of case finding. However, the average citizen is usually satisfied with the school demonstration and is unmindful of the necessity of tracing the source of the infection. Rather than expending money on a program which goes no further than x-raying the reactor, our case finding funds could more advantageously be spent in studying those groups in which the morbidity and mortality rates of tuberculosis are known to be high. In any tuberculosis control program, examination of the contacts is second in importance only to the care of the known case.

Summary

A study of a one dose method of employing PPD in a strength of 001 mgm was made on 3,029 patients attending the clinics operated by the Tuberculosis Division of the New York State Department of Health. Of those who presented evidence of tuberculous infection, 95.9 per cent reacted positively to the test. Among the 3,029 individuals tested, there were eleven instances where the x-ray revealed evidence of tuberculous infection, and in whom the test was negative. Positive reactions were obtained in 1,480 (48.9%) individuals. The number of 4+ reactions obtained by this method was high, i.e., 185 individuals or 12.5 per cent of all reactors. It is interesting in this connection to note the results of a comparative study of OT and 1 PD made by the Division of Tuberculosis, New York State Department of Health in 1,747 patients of the Newark State School which was reported at the 1936 meeting of the National Tuberculosis Association in New Orleans. As part of the study, a dosage of 0005 mgm PPD was employed and it was concluded that this strength dose might be productive of too many 4+ reactions.

Conclusion

As a result of studies conducted by the Division of Tuberculosis, New York State Department of Health, it is concluded that

1 A single dose tuberculin test employing 001 mgm PPD is productive of too great a percentage of 4+ reactors to be generally employed.

2 A single dose tuberculin test employing 0005 mgm PPD might also be productive of too many 4+ reactions.

Obviously, further study is indicated to determine the optimum amount of PPD to be used in a one dose method.

3 In Westchester County, our new cases of tuberculosis give a history of contact, at some time in the past, with cases of tuberculosis outside the county health area and in many instances outside of the state. A few of our cases apparently developed tuberculosis from sources in Europe.

4 Some contacts, presumably with primary infection, developed the reinfection type of tuberculosis from a second contact which has been made just a few months prior to the development of their active diseases. A recent case coming to the attention of the Tuberculosis Division had a primary infection occurring in Nebraska. This girl gives a history of recent exposure to another case in New York City and has developed active pulmonary tuberculosis.

DR. N. STANLEY LINCOLN, *Mount Morris*
—In the critical consideration of the technic and dosage of a test such as the tuberculin test, it is desirable to keep in mind the fundamentals such as (1) the type of test—also implying its relative accuracy—and (2) the purpose for which it is performed.

When a person becomes infected with a B tuberculosis, he develops a condition known as allergy or protein sensitivity. The tuberculin test is designed to determine the presence or absence of this allergy and in a very crude or rough manner give an idea of the degree of sensitivity. This condition of allergy when present is believed to be highly specific and the test is highly accurate and dependable when properly executed.

It is of very material practical assistance to all of us that a product such as PPD with consistent characteristics has been obtained. In a search, for a single test, there still remains an important factor to be reckoned with. It has been estimated, by those most expert and experienced in this field of study that the difference in degree of sensitivity of various individuals may be in the magnitude of one million. In other words, the extreme difficulty is at once apparent. The choice of technic, therefore, is definitely

related to the reason for using the test. In general it can be seen that these reasons are two: (1) To study a group, and (2) to study a single case. In a study of a group, we are primarily interested in determining the total number of reactors with accuracy and with the minimum number of 4+ reactions, which are unpleasant but otherwise not harmful. The subsequent and proper use of this data and its relationship to case finding has been brought out nicely by Dr. Deegan. On the other hand, I believe that the tuberculin test in the diagnostic study of individual cases in clinics, hospitals, and by private physicians has been too long and too much neglected. It is here that the single dose test may find its best application. This is illustrated by the paper presented by DIS of Tbc, S D H at N.T.A. in N.D. It is significant in their study of 1747 inmates in the Newark State School that that minimum dose which gave only seventy-two per cent of the total number of reactors did disclose all but two of the cases of significant pathology, one of which was a terminal case.

There is a study now in progress in rural northwest Minnesota where the total percentage of reactors even to large doses is only about six per cent in a study of about 5,000 individuals. The inference from this is that the degree of tuberculinization of the group studied is another factor to be considered in determining the dose or doses to be used.

Therefore, it is a mute question whether there will ever be a practical single test dose which is universally applicable and which will give the optimum number of reactors and still not give too many 4+ reactors.

The choice of single or multiple test doses must in our opinion be related to the problem at hand.

The problem of extending the span of human life will be attacked from a new angle, that of diet in the last half of adult life, in a six-year experiment at Cornell

University. President Farrand has made public a gift of \$42,500 by the Rockefeller Foundation to support the new study for six years.

the contact group, there is no evidence presented that would indicate an increased amount of pulmonary tuberculosis in the contacts although they are known to have more childhood infection.

Dr Deegan states that in any tuberculosis program, contact examination is second only in importance to the treatment of the known case. We have carried on a tuberculosis control program in Westchester County for the past five years in which examination of contacts has been a prominent feature of the work. We estimate that about sixty per cent of our clinic activities are for the purpose of supervising contacts of tuberculous families. However, the yield in pulmonary tuberculosis from these families constitutes less than ten per cent of the total number of cases of tuberculosis reported each year.

The average annual number of new cases of tuberculosis reported in the Westchester County Health District is 350. Of these cases, 125 are reported by private physicians on patients who have consulted their doctor because of symptoms. The general hospitals in the district report about sixty-five cases annually in patients who have been admitted with a diagnosis presumably other than that of tuberculosis. The tuberculosis clinic service reports 150 new cases each year of whom 120 are among patients admitted to the clinic for some reason other than that of contact with tuberculosis. Thirty cases of pulmonary tuberculosis occur in the contact group but since the use of tuberculin in the clinic is limited to persons under sixteen years of age, we have not discovered a single case of pulmonary tuberculosis as a result of tuberculin testing in the clinics. The thirty cases of tuberculosis discovered have all been in the young adult group where tuberculin tests are not routine. Our school service yields about ten cases of tuberculosis annually and in five years we have discovered four cases of tuberculosis in our schools as a result of tuberculin testing. The remainder of our school cases are found as a result of the x-ray of faculty members or children over sixteen years of age. It has been our experience that there is as much tuberculosis among the faculty members of school groups as among the school children.

The tuberculin testing program in Westchester is divided into three general groups, namely, clinic groups, school groups, and institutional groups. In all cases, tuberculin tests are limited to individuals under sixteen years of age. The results of our testing program is tabulated in the accompanying table.

Group II in the institutions consists of

a group of children previously tested and from whom all cases of pulmonary tuberculosis had been excluded prior to the testing by the County Department of Health.

In contrast to this study, it is interesting to note the result of a study made on young adult contacts for a three year period, 1932 to 1934 inclusive. This study included contacts between the ages of sixteen and thirty-five located from cases reported to the Health Department between 1920 and 1934. During that period, approximately 4200 cases of tuberculosis were reported to the Health Department. On January 1, 1935, 1370 of these cases still remained on the tuberculosis register as active cases of tuberculosis. From this tuberculous population, 2600 young adult contacts were located. Fifteen hundred of these contacts were examined and x-rayed in a three year period and ninety were found to have pulmonary tuberculosis. During that same period, 1061 new cases of tuberculosis were reported from sources other than contact examination, so that less than one out of twelve new cases were discovered as a result of contact examination in young adults.

After a case of tuberculosis has been discovered, we are able to trace to a known source of infection in about fifty-five per cent of cases, establishing the fact that about fifty-five per cent of our cases of tuberculosis can be proven to have had contact with cases of tuberculosis. It is evident, however, that something is lacking in our follow-up of contacts. The difficulties which present themselves are these:

- 1 In handling known cases of tuberculosis about twenty-five per cent of the contacts to these cases have disappeared from association with the known case.

- 2 In a number of cases the time which elapses between contact with a previous case and the development of the disease in the secondary case may cover a period of years. This can be illustrated by two examples. Recently a case of tuberculosis came to the attention of the Health Department with this history: (1) The patient is fifty-eight years old and has suffered from tuberculosis since 1921. His father was a naval surgeon who died in 1888 of tuberculosis. There is no other history of tuberculous contact in this man from 1888 until 1921. During that period he married and raised a family of four children, three of whom have completed a college education and the fourth is at present in college. None of these children show any evidence of tuberculosis. The tuberculous contact history in this case shows a lapse of nearly thirty years before the development of the secondary case. (2) Another instance is that of a case of a young adult who has been carried as a contact in the clinic service since 1926. There has been no contact since 1929. In January 1936, this contact developed pulmonary tuberculosis.

Inventory Time

The report of the Community Nursing Service in New York State for the period from February 15, 1933 to July 1, 1936 details a vast amount of work, for the most part well done. On the whole the Service may be assumed to have fulfilled its dual purpose, i.e., during a period of economic emergency to provide nursing care for the unemployed and needy and furnish work relief to nurses without employment.

Today, however, as relief promises to become a permanent institution in spite of brightening economic prospects, critical appraisal of the numerous agencies set up during the emergency is desirable, to determine, *first*, whether their activities are still necessary, *second*, whether their course brings them into unfair conflict with private interests, and *third*, in the event that their continuance seems advisable, whether their scope or methods should be altered.

In the case of the Community Nursing Service, assuming that most of the work done has a commendable and even necessary purpose, a question still arises as to the degree and effectiveness of the cooperation between the Service and the medical profession and the limits set to the nurses' independent activities. In arranging for the "correction of defects," does a nurse or doctor decide that a defect is present and its correction indicated? How far are nurses permitted to go, without medical supervision, in the prescription of diets for children and care in pregnancy and chronic illness?

These are important points and the Report of the Community Nursing Service does not make them entirely clear. "A supplementary state wide program of public health nursing with special emphasis on bedside care" can undoubtedly accomplish a great deal of good provided that it is carried out in active cooperation with the medical profession and does not attempt to substitute nurses for doctors in the administration of medical care. If

this Service, instituted as an emergency measure, is to continue indefinitely, constant and close contact should be maintained between it and organized medicine

Legal Problems of Artificial Insemination

The practice of artificial insemination has attracted considerable attention among the laity as well as the profession during the past few years. Where proper physical indications for it exist, it has been attended with astonishing success.

There are certain legal considerations, however, with which the physician must be familiar before he undertakes to perform an artificial insemination. The wife must be protected against subsequent divorce proceedings on the ground of adultery. If no living record is kept of the consent of both husband and wife to the artificial insemination, he may at any time offer as proof of adultery his own sterility and his wife's issue.

The legitimacy of the child also comes into question. Of course, legal adoption would solve this problem as far as the husband is concerned, but this would publicize what is desired to be kept secret. The child must also be protected against the eventuality that the mother herself might contest its right of inheritance on the ground of illegitimacy. Since such a situation has as yet not come before the courts, it would be well for the physician to obtain legal advice on this phase of the problem before he practices artificial insemination.

The couple must also be protected against possible blackmail by the donor, and the latter, if married, must be guarded against any action by his wife for adultery. Seymour and Koemer¹ offer many excellent suggestions along these lines to which should be added the expert advice of a lawyer.

EDITORIALS

Answered for All

"Who Wants Socialized or State Medicine?" The answers furnished to this question by the Michigan State Medical Society paint a revealing picture of the attempt of a few paid reformers and ambitious politicians to foist compulsory health insurance upon an unwilling nation. The situation in Michigan is in no major feature dissimilar from that in New York. Here as there, no spontaneous demand exists for a radical revision of the present system of private medical care. Such pressure as is exerted upon legislators comes from seekers after personal profit who see in compulsory health insurance an opportunity for jobs, financial gain, or political power.

The great majority of people have no serious complaint against the type of service they receive under the present system. They know that no one need go without medical care for want of money. They see a steady decrease in morbidity and mortality rates and a lower incidence of preventable diseases like diphtheria than in any country with compulsory health insurance. They know that their physicians have no duty save to prevent and cure sickness and that under a system of free competition success depends on doing this job—and this job only—well.

On the economic side, the American public is astute enough to realize that

there can be no diminution in the costs of medical care under a system which sets up an elaborate political bureaucracy and requires a nonmedical worker for almost every physician rendering service. Government can make no gifts. Ultimately the worker must pay for the "benefits" of compulsory health insurance—in lower income, increased living costs, and higher taxes. Even if he never needs or receives any of the benefits, he still must pay. Since less than nine per cent of the people want for medical care for any reason under the present system, the odds are heavily against the small wage earner under compulsory health insurance. Each week he must make a definite, real sacrifice for highly uncertain future returns.

If compulsory health insurance really could effect the millennium promised by its supporters—lower the costs of medical care, raise the physician's income, and strengthen preventive medicine—the medical profession would be its staunchest advocates. The almost unanimous opposition of medical men is a conviction, based on observation of European experience, that compulsory health insurance sacrifices quality to quantity in medical care, degrades the physician economically and scientifically, and encourages malingering and hypochondria in the insured.

because of the arrival of prosperity. This program is not an emergency one, except in the sense that much of it is long overdue. Nor let it be forgotten that some of the most serious shortcomings of medical practice—those which are just as unsound from the social viewpoint as from the doctor's own selfish viewpoint—such as the abdication of leadership in personal preventive medicine to outside health agencies, public and private, and the perversion of clinics into a settled imposition upon the attending physician and a thriving incubator of the pauper spirit among the patients—these and other dangerous tendencies which are only appreciated as such in bad times, had their beginnings and their growth in times of prosperity when the doctors who influence the policies of organized medicine were too busy and too comfortable to notice or to care.

"Can organized medicine abandon its program when the heigh-ho days return? Let hindsight be the preceptor of forethought"

"WHATEVER THE FUTURE HOLDS for man and for the civilization he has created, there is no question that medical practice and the medical profession will play a major part. It therefore behooves the scientists and teachers having to do with the medical picture, the trustees and faculties of medical schools throughout the world, to closely cooperate in solving these problems which loom so clearly on the horizon in order that the relation of medical research and medical practice to man shall be properly coordinated, so that he shall fit his environment and his environment shall be congenial"—From the *Weekly Roster and Medical Digest*, Philadelphia

"* * * THE QUEST FOR A POLICY that will not only preserve the achievements of the past, but also open the way to progress, will continue endlessly, somehow, as long as men walk this earth"—Raymond Moley, in the November 14 issue of *Today*

GERMS AND PRESCRIPTIONS

When Dr. Brown writes a prescription at the bedside of a patient suffering from a virulent septic disease—is it possible that the prescription itself may carry to the compounder the very disease it seeks to combat?

Yes! according to Dr. Kosowski, of Warsaw (*Pharm Jour*, London, p. 135, 1935).

Dr. Kosowski found that there was a marked difference in the dangers, depending upon the kind of paper upon which the prescriptions were written.

Straw cellulose paper carried more germs than wood pulp, paper with gelatin and

starch as an ingredient was distinctly favorable to the growth of micro-organisms, but if vegetable mucilage was an ingredient the micro-organisms did not thrive.

He examined 360 prescriptions, which he had collected from various pharmacies in Warsaw, and found that they were all contaminated with dangerous organisms.

Of course, dollar bills or any other bills carry the same possibility excepting that they pass through many more hands than the prescriptions.

Anyhow—germs or no germs—prescriptions and dollar bills are altogether too scarce—*Am Jour Pharm*, August, 1936

NO TYPHOID DEATHS IN TWENTY-FOUR CITIES

New York State is not represented in the honor roll of twenty-four large cities which had no deaths from typhoid fever in 1935, a fact made all the more striking when it appears that thirteen of the twenty-four cities are in neighboring states all around us—two in Pennsylvania, five in New Jersey, and six in New England. The annual report on this disease is printed in the *A.M.A. Journal*. The twenty-four cities are Bridgeport, Conn., Cambridge, Mass., Elizabeth, N. J., Erie, Pa., Fort Wayne, Ind., Grand Rapids, Mich., Jacksonville, Fla., Jersey City, N. J., Long Beach,

Calif., Milwaukee, Wis., Newark, N. J., New Bedford, Mass., New Haven, Conn., Omaha, Neb., Paterson, N. J., Peoria, Ill., San Diego, Calif., Scranton, Pa., Somerville, Mass., Springfield, Mass., Tacoma, Wash., Trenton, N. J., Wichita, Kans., and Youngstown, Ohio.

Eight of these cities—five of them in New England—had no deaths either from typhoid or diphtheria in 1935. They are Bridgeport, Cambridge, Erie, New Bedford, New Haven, Scranton, Springfield, and Tacoma.

Shock

True shock is simulated clinically by many other conditions while pathologically the visceral changes are rarely noted. Moore¹ states that essentially shock is a circulatory deficiency evidencing a decrease in the blood volume and cardiac output and hemoconcentration. Clinically it is characterized by increased pulse, lowering of the blood pressure and basal metabolism, and impaired renal function.

In many respects hemorrhage, cardiac failure, extensive burns, and syncope may resemble shock. The reason for this similarity is due to the fact that the circulatory disturbances of shock result from the difference between the vascular capacity and the volume of blood. Any of the above conditions can produce this disparity, some by actual loss of fluid or blood, others by vasomotor disturbances. In none of these, however, do we have all the clinical and laboratory phenomena of shock together.

Pathologically, the findings in shock are like those noted in passive congestion. Moore feels that the congestion found in shock cannot be termed either passive or active in the sense that these terms imply. He feels that "acute venous congestion" is a more suitable term.

CURRENT COMMENT

"FINANCING OF THE SOCIAL SECURITY program from a tax on wealth, rather than on 'wage earners envelopes,' was demanded today by William Green, president of the American Federation of Labor.

"In an editorial in *The American Federationist*, the labor head urged union members to 'work steadily for amendments that will represent a true measure of social security'.

"While the present law constituted 'a great advance,' he said, the old age benefit plan is 'a sort of compulsory savings' program.

"The old age benefit plan provides for only a portion of our population and in part if not in whole represents pennies taken from pay envelopes—a sort of compulsory savings,' he said.

"When we realize the thousands of families that do not have enough income to provide adequate food, clothing and common comforts of living, we realize that funds for social security should not come from wage earners' envelopes directly or indirectly but from a general tax on the wealth they help to create."—From the *New York Herald-Tribune* of November 13.

"THE ONLY PEOPLE WHO HAVE BEEN SO concerned over our derelictions toward the sick and afflicted have been the professional advisers and busybodies who either are wealthy, do not have to worry about a living, and are quite willing, even eager, to direct the destinies of the medical profession, uninvited and unsought, and the writers of articles for public consumption, whose sole interest in the matter is in direct proportion to the sums received for the articles"—These people are "Our Critics" according to the *Milwaukee Medical Times*.

"THE STRUGGLE HAS JUST BEGUN" claims an editorial in the November issue of the *Westchester Medical Bulletin*, from which we quote a considerable part. "As business conditions improve, one hears more and more frequently the casual observation that the medical profession will probably find it possible henceforth to refrain from entering into any new programs or studies calculated to assure medical leadership in solving socio-medical problems, to extend medical participation in public health work, or to improve the collective economic position of physicians—and that perhaps some of its present activities in these fields can be abandoned with the arrival of prosperity.

"This suggestion is admissible only if one can assume that organized medicine today is *more than* fulfilling its responsibilities and obligations to the society in which it exists, that there are no important failures in the distribution or availability of medical care to the public, and that the economic status of the physician is not susceptible of further amelioration by his professional organization.

"If we try to chart the degree of success or failure that the organized profession has achieved to date in respect to each of these criteria, our result is a complicated picture in which glorious accomplishment in one field is contrasted with rather conspicuous shortcomings in another * * * *

"Organized medicine will be able to abandon none of its present essential program

in which I adduced evidence indicating that vasomotor rhinitis, as well as the allergic diseases, develop on the basis of a constitutional predisposition consisting of retention of water and mineral substances. I also attempted to show that the development of the so-called common colds—notoriously associated with rhinitis in the great majority of cases—is made possible by a similar disturbance in the water and mineral metabolism.

In the therapy and prevention of vasomotor rhinitis, the allergic diseases and colds, I suggested measures aimed at the elimination of retained liquids and at the prevention of subsequent retentions. These measures include the administration of calcium which also appears in the mixture employed by Dr Kaplan. Mainly, however, the therapy consists of a diet which I call "antiretentional" (a low calory diet, rich in proteins, nucleoproteids and vitamins, and restricted in carbohydrates, fats, water, and salt), and which has proven its merit, not only in my cases, but also according to the observation of others. Thus in an article which was published in the

Lancet (1 1070, 1935), H W Barber writes the following:

As an example of the remarkable effects of an antiretentional diet the following case may be cited.

A boy of 15 was referred to my out-patient department by one of my colleagues last summer for a recurrent impetiginous anterior rhinitis, which nearly always resulted from his frequent colds. He was subject to repeated asthmatic attacks, and had so-called functional albuminuria. His mother stated that the boy consumed large quantities of sweets, jam, pudding, cake, and bread, his intake of fat was probably also excessive. I advised a strict antiretentional diet, which the mother promised to enforce. A fortnight later I saw the boy again. His rhinitis and chronic catarrh had cleared up, the albuminuria had disappeared, and his mother was astonished at the improvement in his general health. Since that time he has had no colds and has been entirely free from asthma, except at Christmas when his mother allowed him to relax his diet. He then promptly "caught a cold" and had several asthmatic attacks. Since resuming the diet he has been perfectly well.

Very truly yours,

EUGENE FÖLDES, M D

DR WINSLOW'S USEFUL HOBBY

The many members of county medical societies who have had the pleasure of hearing the genial President of the State Society tell stories of his experiences as medical examiner may be glad to have some of them preserved in print. This is made possible by the enterprise of the *Utica Press*, which recently reported the reminiscences of Dr Winslow as given at a meeting of the Oneida County Medical Society. The reporter first informs the readers that instead of fishing or following some sort of hobby, Dr Floyd S Winslow spends his spare time solving murders, performing autopsies and unraveling the many peculiar forms of violent death.

For twelve years he has served as coroner's physician in Monroe County. In that time he has developed a library of slides and a succession of weird stories which has made the average man's hobby look like an exercise in embroidery.

A man in whose conviction Doctor Winslow played a major part and who had threatened revenge, broke out of jail. Doctor Winslow was warned that the man was on his way back to Rochester and that he might try to get him.

The physician's son offered consolation, telling his father that even if the convict killed him, he would get the murderer. The

family was relieved of this unpleasant duty when police killed the convict near Rochester.

Among his many friends, Doctor Winslow had a man who proved unusually obliging. This man, a druggist, one night suddenly left the family circle, locked himself in the bathroom and collapsed. The coroner could find no evidence of poison in the bathroom and the family knew of none in the house.

When Doctor Winslow performed the autopsy, he found in the man's stomach, the label from a package of potassium cyanide. Doctor Winslow believes that his friend had swallowed the label to make it easier for him to determine cause of his sudden death. Apparently he had wrapped the poisonous powder in the label, with the gum arabic face outside. This made it easier to swallow.

The stomach juices melted the powder as the packet unwrapped and death came in a minute or two. Had it not been for his friend's forethought, a chemical analysis of the stomach's contents would have been necessary.

Another interesting case was that of a respectable contractor of Rochester who in a short period lost both his money and his wife.

(Continued on page 1897)

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked "private." All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

Priority

To the Editor

1205 Dean St,
Brooklyn

In the December 1, 1935 issue of the NEW YORK STATE JOURNAL OF MEDICINE, Vol 35, No 23, p 1217, appeared an article by Dr Milo Fritz and myself entitled "The Novocain Pack, a Contribution to the Therapy of Fresh Accidental Wounds," in which we set forth a chance discovery by us that novocain applied to fresh wounds confers a degree of anesthesia sufficient to minimize or even remove the pain of suturing. This was new to us then, but during the past summer we have learned that we were not in fact originators of this use of novocain.

Dr Walter R Hewitt of 3615 Orchard Street, St Louis, Mo, originated the method as evidenced by his article which appeared in the *Journal of the Missouri State Medical Association*, Vol xxvi, No 8 for August 1929, p 395, under the title "A Physiological Method of Treatment of Accidental Wounds." He also fell on this small but useful discovery by chance.

We, of course, not having seen the *Missouri Journal* were unaware of the previous publication, and we are very happy to accord to Dr Hewitt full credit for his well-deserved priority.

I hope you will have space for this letter for the information of our readers.

Sincerely yours,

E K TANNER, M D

November 10, 1936

Endorsement of Foreign Physicians

1 E 63rd St,
New York, N Y

To the Editor

I read your editorial concerning endorsement of foreign licenses. How much better it would be to endeavor to utilize the Australian, English, German, French and Italian methods whereby they will not recognize any American graduate unless, first, he becomes a citizen of their country, secondly that the country that he comes from reciprocates in full and on an actual basis that is the same, for their degree! Our silly method of licensing by endorsement or recognizing foreign schools and countries that

will not recognize ours is too inane to hardly mention. In other words let us reciprocate with foreign countries on the same basis that they reciprocate with us. When New York State physicians pass that law, then they will have something worthwhile. All the rest of it is just marking time.

Very truly yours,

THOMAS J KIRWIN, M D

November 10, 1936

Cod Liver Oil as a Dressing

105 E 63rd St.
New York City

To the Editor

The November 1st issue of the STATE JOURNAL carries an abstract of an article relating the value of cod liver oil as a wound dressing. I wish to inform you that I have used cod liver oil in ophthalmological practice for the past five years. I employ it in cases of epithelial dystrophy of the cornea by instilling it into the conjunctival sac and then gently massaging the cornea through the closed lids. The results have been excellent.

Yours truly,

JOSEPH LEVINE, M D

November 10, 1936

Vasomotor Rhinitis

898 Park Ave,
New York, N Y

To the Editor

In the NEW YORK STATE MEDICAL JOURNAL for November (Nov 1, page 1655), an article appeared by Dr Samuel Kaplan on "Vasomotor and Atrophic Rhinitis. Relation to Body Fluids and Sodium Metabolism." In this contribution the statement is made that "the writer firmly believes that vasomotor rhinitis in itself is not an allergic state, but is the result of faulty fluid and sodium balance." I wish to call your attention to a publication (Eugene Földes, *A New Approach to Dietetic Therapy, etc, Metabolism of Water and Minerals and Its Disturbances*, R G Badger, Boston, 1933),

the operation of a rehabilitation clinic or bureau under Section 13-J of the Law. Nothing herein contained affects the right of transfer as provided in Section 13-a (3).

Rule 3 When a medical examination is had under Section 13-a(4) it shall be by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, if in the latter's opinion his presence is necessary. A duplicate copy of all notices of requests

for examinations must be sent to the attending physicians.

Rule 4 No physician designated by an insurance carrier or an employer as a consultant, in the case of an injured employee, shall subsequently participate in the medical or surgical care of said injured employee, except with the written consent of the injured employee and his attending physician. Nothing herein contained affects the right of transfer as provided in Section 13-a(3).

November 20

We have been requested to secure the cooperation of all authorized physicians in *promptly closing* a case in which they have completed the treatment. The physician should complete his treatment of the patient as soon as feasible and render a bill for *services promptly*. Delay in rendering a bill, and, in a protracted case of informing the carrier of the completion of the case, results in great inconvenience, not only to the physician but to the injured claimant, employer, and carrier, alike. The payment of bills will be greatly facilitated by the prompt

submission of bills with a notation concerning the completion of the treatment of the case.

In prolonged cases (not coming under a fixed time schedule for treatment) progress reports should be submitted and bill rendered *periodically*. Physicians are requested to give their utmost cooperation in speeding up the administrative details incident to the amended Workmen's Compensation Act.

DAVID J. KALISKI, M.D., *Chairman*

FREDERIC E. ELLIOTT, M.D.

B. WALLACE HAMILTON, M.D.

(Continued from page 1895)

through death. This man was seen outside a factory for seven successive weeks on the morning the payroll was brought by armored car. On the eighth week, the police were summoned.

When an officer started questioning the man, he shot the policeman through the hand. As he ran away, a second prowler came up and officers fired three shots. They appeared to hit the fugitive in the back but he was not stopped. The policeman changed his aim, raising his gun and the fourth bullet brought the man down, instantly killed.

When the body was brought to the morgue, Doctor Winslow found the man had encased his body in a suit of home-made armor. The metal, regular boiler plate, was hinged about his trunk, completely protecting the vital organs.

Three dents, made by the first three shots, showed in the back of the armor. The fourth shot had slipped above the plate and struck his neck which was unprotected.

A little more scientific is the story of the bootlegger who was shot early one morning. A Rochester milkman told police he had seen a colored woman in that block about the time of the shooting. She was located but there was no evidence linking her to the crime.

Finally Doctor Winslow put under the

microscope scrapings from under her fingernails. He found a mixture of potato peelings and skin of a white man. The woman then confessed.

Doctor Winslow firmly believes that just as physical evidence at the scene of a crime indicates the criminal, in exactly the same way bodies put through an autopsy always show the method and circumstances of criminal assault and death, and this evidence is invaluable in prosecuting criminals.

He cited a case where four men attempted to rob a gas station and garage. The owner, who had been robbed once before, was ready, hiding in a dark corner with an automatic rifle. When the three men (the fourth was the driver, left in the car) came into the garage, the owner opened fire. The thieves returned the fire with their pawn shop revolvers. At the end, two of the intruders were dead and the third was badly wounded.

Doctor Winslow's testimony, based on the autopsy, showed that in the battle in the dark one of the thieves had been killed by a bullet from a confederate's gun.

As a result, the surviving members of the party were convicted of murder, first degree, under the state law which makes all participants in a crime guilty of murder, first degree, if anyone is killed during execution of the crime.

COMMITTEE ON WORKMEN'S COMPENSATION

In advance of the promulgation of rules and regulations governing the licensing and conduct of *physicians compensation medical bureaus*, the Committee on Workmen's Compensation wishes to draw to the attention of all physicians practicing under the Workmen's Compensation Act the necessity of signing all forms and reports issued under the amended Workmen's Compensation Act with the full name of the attending physician as well as his authorization number and symbol

If a rubber stamp is used for legibility, the attending physician must in addition personally sign his own name. Where more than one of a group of physicians has treated a case, unless one physician assumes

full responsibility, each physician should sign the report or form and indicate the dates on which each participant in treatment attended the patient. This procedure is necessary in order to protect the interests of the claimant and to enable the referee of the Department of Labor to ascertain the name of the physician or physicians treating the patient.

It is advisable for qualified physicians to keep adequate records of the history and treatment of each claimant patient in such form as will enable the attending physician to render satisfactory reports and give proper testimony before the Department of Labor in the event that the physician's testimony is required.

November 12

The attention of physicians qualified under the Workmen's Compensation Act is directed to section 13(a) of Chapter 258 of the Laws of 1935.

The Law reads

The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule. Nothing in this schedule, however, shall prevent voluntary payment of amounts higher than fees and charges fixed therein, but no physician rendering medical treatment or care may receive payment in any higher amount unless such increased amount has been authorized by the employer, or by decision as provided in section thirteen-g herein.

Nothing in this section shall be construed as preventing the employment of a duly authorized physician on a salary basis by an authorized compensation medical bureau or laboratory.

Physicians are hereby notified that to enter into any contract with an employer for the treatment of patients for a fee less than

that contained in the schedule is a violation of the Law punishable under Section 13-d (d) by removal from the list of physicians authorized to render medical care.

Physicians who have in the past entered into such contracts are hereby advised that they are not in accordance with the provisions of the law and must be terminated at once. Under the strict interpretation of the Law such contracts became illegal on July 1, 1935. In view of the *status quo* arrangement pending the promulgation of the fee schedule by the Industrial Commissioner, physicians who had entered into such contracts were permitted to fulfill them until the fee schedule was promulgated. All such contracts which contravene the provisions of the Law in respect to the minimum fee schedule are definitely illegal and unless terminated at once will result in action by the County Society or the Workmen's Compensation Board of the County Society.

November 17

In order that all communications by insurance carriers to their policyholders relative to medical care of employees shall be in conformity with the Compensation Law and the rules and regulations promulgated by the Industrial Commissioner regarding the free choice of any physicians on the panel, the following rules have been promulgated.

Rule 1 The supplying of names of authorized physicians by insurance carriers to their policyholders is in contravention to Section 13, as amended by Chapter 258 of

the laws of 1935. Such policyholders and all employers may secure a list of all Authorized physicians in the vicinity of their places of business by applying to the Industrial Commissioner of the Department of Labor.

Rule 2 Any physician who acts in the capacity of medical inspector for an insurance carrier or employer in the case of an injured employee under the care of another physician shall not participate in the treatment of said injured employee except in

VI Physical Diagnosis (a) Recognition of conditions in the mouth capable of acting as foci of infection—X rays, transillumination and pulp testing as diagnostic procedures (b) Recognition of other conditions prejudicial to health—carries unerupted teeth, malocclusion, faulty dentures etc.

VII Medicine and allied specialties The relation of dental conditions to general diseases

VIII Surgery and allied specialties In addition to covering oral surgery the importance of dental infections as causes of various general surgical conditions and the necessity for dental care in addition to other surgical procedures should be stressed.

4 In the senior year, one to three lectures correlating all the facts presented in the different courses should be given preferably by a dentist of wide experience.

5 Every medical student should have a full mouth dental X-ray taken

Obstetrics

Obstetric patients should make regular visits to the dentist during the entire course of gestation

1 Prophylactic dental care

A Hygienic care of the oral cavity

B Diet for expectant mother Influence of diet on teeth of mother and offspring, influence of vitamins, influence of viosterol (cod liver oil)

C Focal infection—factor in toxemia of pregnancy and sepsis (postpartum)

2 Active dental care during pregnancy for acute conditions which may include

A Extractions, fillings, root canal treatment, apical abscess, removal of benign neoplasm, gingival hypertrophies, pyorrhea

B Anesthesia Local or Block, and general.

3 Medical-dental conference about case, progress notes

A Medical-dental conferences should be held when the dentist is in doubt about his patient's general health.

B The medical attendant should keep with his records the dental diagnosis and notes furnished by the dentist on the treatment he rendered to the patient.

C The physician should note whether or not there is improvement in general health of patient

Recommendations for Dental Schools

1 *Supplement courses in general pathology by more practical clinical observation* Courses in general pathology should be supplemented by more clinical observation of the conditions causing the morbid tissue conditions covered in the lectures and laboratory instruction. The correlation should be extended to clinical observation of the course of infections studied, so that lectures and laboratory examinations may be tied in definitely with clinical symptoms

2 *Courses in Maxillo Facial Surgery should provide actual hospital operative experience* The courses in Maxillo Facial Surgery do not give enough hospital contact and experience. The men do not actually work, themselves, under hospital conditions. Therefore, provision should be made for dental students to actually do operations in the hospital for sev-

eral days. Even if the operation is a simple extraction, the students should prepare in the same manner as if a major piece of Oral Surgery was to be done. Only by actual participation can the proper feeling and understanding be given to these men

3 *Courses and assignments in oral diagnosis to be extended to actual medical and dental cooperation* Particular stress should be laid on the relationship of dental infection to disease elsewhere in the body. Physicians and dentists should cooperate in making the diagnosis. The case should be worked up by both professional groups in the presence of the students and a complete program for health rehabilitation determined upon so that the dentist will know what effect may be expected to result by his prevention of, or elimination of infection in his particular area, and what effect will be had upon the dental efforts by the elimination of infection, and alteration of systemic disturbance by the physician.

4 *More actual practice training should be provided* In those universities having the Medical School Hospital available, efforts should be made to provide each student with actual residence within the hospital under competent supervisors, even though the time may be only one week. First, more actual knowledge of hospital procedures, practice, care of the sick and gravity of dental service will be obtained by the student, and second, more students will be stimulated to seek appointments to hospital service internship after commencement.

5 *Medical and dental student's health examination* Every dental student should have in his third or fourth year a thorough physical examination following the above ideas, and a written report submitted by the student, analyzing his own condition and making specific recommendations for treatment, should be provided.

Actual experience in clinic and classroom will soon produce further advancement of teaching to better impress the student dentist that his every service is a health service, that the physicians aid should be sought frequently, and that aid and cooperation should be given freely to the physicians at all times

The Committee is constituted as follows
First District Dental Society, Theodore Blum, M.D., DDS and Roy D. Ribble, DDS,
Second District Dental Society, William McGill Burns, DDS, Lawrence J. Dunn, DDS and Orville S. Long, DDS, Bronx County Medical Society, Maurice O. Magid, M.D., Kings County Medical Society, Albert F. R. Andersen, M.D., N. Y. County Medical Society, John Stanley Kenney, M.D., Queens County Medical Society, Frank R. Mazzola, M.D., Richmond County Medical Society, Mortimer B. Genauer, M.D.

It invites opinions and suggestions on these recommendations. They may be addressed to the Secretary, M. O. Magid, M.D., 1018 E. 163 St., New York City

The 1936 annual joint meeting will be held

MEDICAL-DENTAL TEACHING

Organized six years ago by the five county medical societies and the two district dental societies to arrange programs for combined meetings of physicians and dentists in the five boroughs, the Joint Committee of the Organized Medical and Dental Professions of Greater New York has not only fulfilled well its instructions but also made a special contribution in the field of professional education

The Committee, listening to the papers presented—at its own instance—to the joint

meetings arrived at the conclusion that the professional pathways cross frequently and that perhaps both medical schools and dental schools might help their students to a wider horizon of knowledge by providing for each group some instruction in the adjoining field of scientific knowledge. It then set a sub-committee to work to scrutinize present teaching of the sort in a number of medical schools and dental schools. The result was a report which was submitted a year ago and is here reproduced

REPORT OF SUBCOMMITTEE ON CURRICULA TO THE FIFTH ANNUAL COMBINED MEDICAL-DENTAL MEETING, DECEMBER 2, 1935

The public is entitled to the highest type of health service from the medical and dental professions. With advancement in science, medical care of the sick has become, in many instances, a problem for group practice. The aids of the laboratory, x-ray, and various specialists are often included in caring for a patient. It is only quite recently that the physician has come to realize the dentist should be included among the specialists to be consulted.

For the past five years the Joint Committee of the City of New York has been encouraging medical-dental cooperation in the treatment of the sick. The Joint Committee has conducted combined medical-dental meetings and arranged programs which attracted large audiences of physicians and dentists. These meetings have become a regular institution in Greater New York. This committee has arranged medical-dental programs for the New York State Medical and New York State Dental Associations.

While considerable progress has been made in reaching the practicing physicians and dentists, the Joint Committee realized that in order to make medical-dental cooperation more general in the future it was necessary that medical and dental schools should be encouraged to teach their students the importance of such cooperation in caring for patients.

To carry out this objective, the committee sent a questionnaire, two years ago, to all grade A medical and dental schools in the United States and Canada to ascertain to what degree the schools emphasized the correlation between medical and dental subjects. The report of this research was submitted at the 1934 Combined Medical-Dental Meeting and aroused considerable interest among the educators present who discussed the report. It was suggested, that knowing the deficiencies of this teaching in the professional schools, it would be of value to have the Joint Committee go a step further—to submit specific recommendations for the improvement of medical and dental curricula in regard to this important but neglected phase of instruction.

Following the adoption of a resolution at the 1934 meeting a subcommittee was appointed to

study the curricula of all Medical and Dental Schools and to report back to this body its opinions and recommendations.

The subcommittee decided that since the curricula of the schools are already overcrowded with courses, and many departments are clamoring for more teaching hours it would be best, for the present, not to suggest any radical departure from present methods, but to attempt to suggest changes which would not materially alter the curricula of the schools, but would use already available hours in the various teaching branches to emphasize the relation between the teeth and general health.

To go into detail as to hours and subjects to be taught would only engender resistance on the part of the schools, so the committee is presenting the following outlines which it hopes will call attention of the educators to the subjects in which medical-dental relationship arises.

Recommendations for Medical Schools

1 The committee is of the opinion that if attempts are made to force too much upon medical schools in this connection they will say they have no room for a course in this subject and will not consider the matter at all.

2 The committee does not believe that it is practicable or necessary to give a complete, comprehensive course in this subject.

3 By calling attention of the various teaching departments to the importance of the teeth in relation to the general health and disease, much can be accomplished toward furthering the cause. The committee therefore makes the following suggestions for the medical curriculum.

I Anatomy and Histology. An hour's special attention to teeth and jaws.

II Physiology. The importance of the teeth in digestion, mastication. Occlusion.

III Pathology. The lesions of the teeth, alveolar processes and jaws and their relation to diseases of sinuses, nose and throat and general diseases.

IV Bacteriology. The teeth and their surrounding tissues as soil for bacterial growth and for dissemination of infections.

V Hygiene. Importance of care, preservation and replacement of teeth to prevent diseases.

A HISTORY OF MEDICINE IN THE STATE OF NEW YORK AND THE COUNTY OF MONROE

FLORENCE A COOKSLEY, B.A., M.A., Rochester
Librarian, Rochester Academy of Medicine

Part II History of Medicine in Monroe County

Chapter I

Conditions in Early Rochester

*Early history of region Jesuits the first settlers the Senecas, Conditions of country
Dangers of English invasion Wild animals Routes of travel Early roads 1806 Erie
Canal 1824 First railroads, 1837 Settlement of Rochester Established 1797 First
bridge, 1812 City incorporated 1817 Settlement of neighboring towns, Rapid growth
Early newspapers quoted*

Monroe County of the State of New York is not one of the old counties of the state, for it was not incorporated as such until February 21, 1821. Until then all that part of it situated on the west side of the Genesee River had been included in Genesee County, which included in addition, half of the present Livingston County. Batavia was the county seat of Genesee County as it is today. Until 1800 Ontario County was even larger than Genesee County, in fact was of great extent as it included the present counties of Niagara, Chautauqua, Cattaraugus, and part of Alleghany County, and had a population of 12,584. In 1810, Genesee County was formed and contained a population of 12,644, which increased in four years to 23,951 persons. As we have stated, the west side of the Genesee River was in this Genesee County at the time of the establishment of Monroe County and the east side of the river was in Ontario County, with Canandaigua its county seat. Ontario County also contained what is now Yates County and the other half of Livingston County. Thus the Genesee River separated the two counties and it is humorously related that debtors escaped the sheriff by running across the bridge.¹ These two large counties, Genesee and Ontario had together 80,000 inhabitants. The rapid rise in population is commented upon in an early newspaper, the *Rochester Gazette* in 1820, thus

New York is not the only state that has thus swelled its population the Southwestern states are arising and joining the confederacy the Floridas will soon be ours and the Canadas are

now at our command but we do not want them Europe may well regard our growing strength with jealousy, if the wise policy of our government be seconded by harmonious co-operation of the states, twenty years more will present America to the world the Lion of the North, powerful in peace and dreadful in war.

The two county seats, Batavia and Canandaigua were considered too far distant from Rochester, for with bad roads and the bridges few and far between, the trip to these towns was difficult and dangerous, particularly in winter when roads became almost impassable and the citizens felt a need of smaller boundaries and an easily accessible county seat. "It is a singular fact," states an editorial in that same paper, "and which should be known at large, that without any business of consequence arising within the limits of Canandaigua, the village of Rochester for the unspeakable privilege of carrying its business to be transacted thirty miles from the place where it arises, pays to the former village, in the mere expense of living at the present circuit, a tribute of at least \$800.00." There was a great deal of objection on the part of Batavia and Canandaigua to the proposed new county. Their citizens urged that the expense of erecting new county buildings would be too great but Canandaigua was then needing a new Court House and the people of Rochester thought they preferred to contribute to their own buildings. After much opposition Monroe County was carved out of the two counties. Being interested especially in the medical history of this county we note that on December 8, 1818, some of the citizens

*Continued from November 15 issue.

on December 7 under the auspices of the Better Dentistry Meeting at the Hotel Pennsylvania, New York City. The program follows:

10 A. M. INVOCATION

Presiding, Clarence J. O'Connor, M.D., Pres. Bronx County Medical Society and James M. Dobbins, M.D., Pres. Queens County Medical Society

Progress Report of Subcommittee on Curricula Study, M. O. Magid, M.D., Chairman.

1 Diseases of the Oral Cavity of Medical and Dental Interest, Samuel Feldman, M.D. Discussion by Leo Spiegel, M.D. and Henry Dunning, D.D.S., M.D.

2 Medical Problems in Orthodontia. Bernhard W. Weinberger, D.D.S. Discussion by Ralph Waldron, D.D.S. and Edward Mason Griffin, D.D.S.

2 15 P. M. CLINICAL MEETING

Presiding, Henry Joachim, M.D., Pres. Kings County Medical Society and Wm. J. Buntin, M.D., Pres. Richmond County Medical Society

1 Lesions in Oral Cavity. Presentation of

Patients—Clinical Pathological and Roentgenological data. Adolph Berger, D.D.S.

2 Vitamin Deficiency Conditions in Children. Presentation of Patients. Reuben Turner, M.D.

3 Clinic—New York Institute of Clinical Oral Pathology. Cases to be presented by Raymond Gettinger, M.D., Herman L. Reuss, D.D.S., and Meyer L. Rosoff, D.D.S.

4 Radical Antrum Operation. Cases illustrating the superiority of the Intranasal Route over the Canine Fossa Approach. Simon L. Rusk, M.D., and Max Halle, M.D.

Note. Discussion or questions after each group of cases.

8 15 P. M. STATED MEETING

First District Dental Society

Presiding, Jacob B. Schneer, D.D.S., Pres. First District Dental Society and Chas. E. Farr, M.D., Pres. N. Y. County Medical Society

1 Executive Session

2 The Responsibility of the Dental Profession in the Early Diagnosis of Intraoral Cancer, Hayes E. Martin, M.D.

AN "ATLAS OF TUMORS"

Dr. Francis Carter Wood, director of the Institute of Cancer Research at Columbia University, announces the preparation of "an extensive diagnostic atlas of tumors" as a means of promoting further study of this disease on an international scale. He spoke at a luncheon held under the auspices of the New York City Cancer Committee at the National Arts Club. The meeting marked the tenth anniversary of the founding of the New York City and State Cancer Committees.

Dr. Wood recalled that the "atlas of tumors" was proposed at the International Cancer Congress in Brussels last September and that the committee on its preparation had commissioned him to start the

work. Wide support has been received from outstanding pathologists abroad for its preparation within the next two years, Dr. Wood said.

"The fact that this volume bears an international stamp," he continued, "will no doubt stabilize our ideas of tumors and lead to the publication of a large number of the rarer types which may have hitherto been somewhat neglected, thus clarifying a good many facts, both clinical and scientific, which are important to develop as quickly as possible inasmuch as the growth of radiation therapy necessitates a more complete knowledge of the biology and natural history of a neoplasm than its mere excision by surgical technique."

FRANCE HAS A "SECRETARY OF LEISURE"

The socialistic government in France has not only brought shorter hours and higher wages for the workers, but has obliged employers to grant annual vacations with full pay. This has led to the appointment of a cabinet minister known as a "secretary of leisure," whose duty it shall be to encourage physical education and to aid the workers to spend to the greatest advantage their non-employed time and especially their paid vacation periods. Information is provided as to where to go, at all seasons of the year, and special railroad or bus round-trip rates

in all directions, even to foreign countries, are arranged for. G. Lavalee in the *Concours médical*, suggests to the "secretary of leisure" that sport competitions, theaters which follow provincial circuits, and increased use of the radio are not innovations but that a serious effort should be made to supervise the omnipresent saloon lest the leisure hours be spent there. At least one or two thousand saloons ought to be suppressed to prevent the free Saturdays and Sundays being passed there by the worker.

1812-14 the British fleet hovered about the mouth of the river, firing a few guns in their maneuvers. In Pultneyville, on the Lake, owners of a very old home proudly point to holes in the walls made by British shots. Sir James L. Yeo was admiral of this fleet consisting of five large and eight small vessels of war and he succeeded in very thoroughly frightening the inhabitants who fled in terror.⁶

Travel to this part of the country was difficult and hazardous. Wild animals abounded, deer, moose, elk, buffalo, bear, wolves, panthers, wild-cats, and smaller animals such as mink, martin, and otters. An early newspaper reported the finding of a dead panther nine feet long in Oak Orchard on the Lake Shore and later that one had been seen in Batavia. In the City Directory of 1844 the historian stated that in 1817 a Mr. Brooks living near what was known in 1844 as the Buffalo bridge, complained that bears had carried off his apples which he had hung on the outside of his house to dry. The last wolf was killed in Monroe County in Irondequoit in 1830. A present inhabitant of Rochester remembers hearing of a doctor in Parma who in those early days, spread asafetida on the snow to keep the wolves away. These various wild animals made travel unattractive and especially to the timid.

Travel was not only unattractive but uncomfortable. A stage road in poor condition, almost impassable in winter, ran as early as 1806 from Palmyra to the falls of the Genesee. In 1816 it was extended to Canandaigua and in the same year Ridge Road was built and became a most important road in the development of trade in this part of the country. In 1827 there were two stage routes between Rochester and Albany and one from Rochester to Buffalo, a fare of three and a half cents per mile was charged. In 1824 the Erie Canal was opened to Rochester and was hailed as a promising new route of travel. During the eight years in which it was being built it was spoken of as the "Grand Canal" and much was hoped for in its use and not in vain. From that time on, the settling of the county was rapid. The fare on this canal was four and one-half cents per mile and in 1834 eight packets plied between Buffalo and Albany, a three and one-half days trip each way or eighty miles in twenty-four hours. There had been

other boats previously, running from Rochester to various places on the lake and some of them traveled up the Genesee River for a long distance. Travel by railroads came later, in 1837 the first train ran to Batavia and in the following year to Auburn, then in 1840 to Canandaigua and a year later to Albany.⁷ One can easily understand how the early development of this country was delayed through lack of traveling facilities.

Most of the early inhabitants of Monroe County came from New England with a few from England, Ireland, Scotland, and Germany, while a very few came from Canada, Norway, and Switzerland. The first Rochester directory, of 1827, states that of the population of 8,000 not one adult was native born.

Rochester itself, was one of the last places settled in the county. The reason ascribed by early writers was its dense forests, the hostile Indians, and the unhealthy swamp lands filled with mosquitos. In 1790, Phelps and Gorham sold the "Mill Tract" which included all of the present Rochester lying on the west side of the river. It was surveyed in 1790, subdivided in 1797, and settling began soon afterward. In 1812, there were three families living on the east side of the river and none on the west side. In 1813 there was a population of fifty, and five years later over one thousand people had settled in Rochester. The only places where the Genesee could be crossed between Avon and Lake Ontario was at Rochester-ville, later called Rochester, where the county built a bridge in 1812, costing \$12,000. "The construction was very violently opposed by many people who said that a bridge at this place was entirely unnecessary as the Avon bridge was adequate for the needs of travelers in the Genesee country."⁸ The Genesee was then a river that frequently flooded its banks and there were several big floods, a very destructive one in 1805, another in 1817 which necessitated the building of dykes in Exchange Street to prevent flooding of the lower parts of the village, another came in the spring of 1832 when the "river covered the flats of the Genesee for twenty miles" at which time the bridges at Mt. Morris and Avon were swept away.⁹ There was another flood long after, in 1865, which flowed over Main Street bridge and over

of the town of Gates held a meeting regarding this proposed change and that with Nathaniel Rochester presiding, a physician, Dr Frederick F Backus, who later appears so often in Rochester's history, acted as secretary of the meeting

Livingston County was also sliced off the two counties at the same time that Monroe County was formed This no doubt was a blow to the two busy towns, Batavia and Canandaigua At the time of all this agitation, Monroe County was spoken of in the newspapers as Rochester County but was incorporated as Monroe, being named after the President of the United States, James Monroe

For the sake of clearness, in this record we will speak of Monroe County as though it had its present name and boundaries since Revolutionary times

In the early records this corner of the State is known as the "County of the Genesee" Genesee is an Indian word meaning "Pleasant Banks" and the word Ontario, we are told, comes from Kayatario, meaning "Pleasant Lake" If the banks of the Genesee and of Lake Ontario were pleasant, they were so only to their namers, the Indians, for all the country thereabout was a wilderness inhabited by hostile Indians, a forest of dense growth penetrated only by occasional paths worn down by moccasined feet. It is said that many of the present Rochester streets are old trails beaten out by the Senecas through the forest.

The first settlers, as in many of the lake regions, were the Jesuits who came as missionaries to the Indians in 1634 Rochester at that time was a camp site called by the Senecas, "Ga-sho-sa-go" or "At-the-Falls" These Jesuit fathers were not welcomed by the Senecas and other members of the Iroquois and their lives were in danger at every step We are told that the Franciscan missionaries had much to do with opening the Genesee country and that most of them came from Canada and spread from the eastern part of the state westward to the Genesee but not going as far west as the site of Buffalo for many years Father Hennepin accompanied La-Salle in 1669 when he explored the region of Lake Ontario and Little Seneca River, as he called the Genesee and he wrote of the wonderful falls and the numerous rattlesnakes We are told further, that "no locality was more unpopular than the

falls', the present site of Rochester, that dismal swamp in the roaring of cataract, that rendezvous of muskrats, mosquitoes and rattlesnakes and with the worst reputation for fever and ague."

The Senecas, early inhabitants of this section of the State, were warriors, blood-thirsty and cruel In 1687 a stockade was built at Irondequoit Bay where twelve hundred men were cared for, sick and wounded The Senecas who had destroyed the Attrouandarouks or Neutral Nation about 1650, except for the few survivors whom they absorbed, had finally come to occupy all this country which had belonged to that Nation Until then, "the beautiful region was abandoned to the undisturbed dominion of nature, save when traversed by the warrior on his predatory errand or the hunter in pursuit of game A dense and unexplored wilderness extended from the Genesee to the Niagara with here and there an interval where the oak openings let in the sunlight or the prairie lured the deer and the elk to crop its luxuriant herbage." After the stockade was built, the Marquis de Nouville, governor of Canada, brought a large invading army and defeated the Senecas near the present site of Victor, burnt their villages and drove them away The Senecas were too superstitious to rebuild their abandoned homes and they scattered into the fertile valley of the Genesee where they cultivated maize and regained some of their prosperity

At the time of the Revolutionary War, the Senecas "espoused the British cause" and committed such atrocities that General Washington sent an army under General Sullivan against them and they were defeated and scattered, never again returning to the Genesee country It is said that the New Englanders and the Pennsylvania Dutch who accompanied Sullivan were amazed at the richness of the land and after the war was ended, many hurried back as settlers By 1815, after all trouble with Great Britain had ceased, Rochester began to grow rapidly and "settlers arrived faster than roofs could be made to cover them, it was not uncommon to see a line of wagons in the main street, occupants living in and under them waiting for the erection of their cabins"

Fear of the English as well as fear of the Indians, is a reason given for the late settling of Rochester In the war of

We are pleased to observe the increasing travel through this village on the Ridge Road to the Niagara Falls. A stage runs this route three times a week, the road is excellent and the accommodations good.

Although Rochester had a population of only fifteen persons in 1812, five years later it had 560 and five years after that, in 1822, it had 2,700. When the city was incorporated in 1834, it had a population of 12,252. A century later, in 1935, the population was 330,000. It is said that in 1834, the growth of the city had been so rapid that houses were scarce and six or even seven families lived under one roof. Few cities, if any, in this part of the country has had a growth as rapid as Rochester and it was due to the improved health conditions and better transportation facilities in a place strategically located.

As early as 1823 Rochesterville had an ordinance requiring sidewalks on both sides of Buffalo Street, later called West Main Street and on Carroll, Exchange, Hughes, and Sophia Streets. At the same time we read that the west side of the Genesee was a dense forest of heavy timber. However, houses were being erected rapidly and because the streets were obstructed by building material, it was thought that streets should be lighted but the city fathers were unwilling to spend the money and voted against the proposition. By 1845 street lighting had been installed, whale oil lamps being used for this purpose.¹²

An editorial in the *Rochester Gazette* of September 19, 1820 is of such interest and so well written that we may well include it in its entirety here.

There is nothing in which American enterprise, boldness and intrepidity is more strikingly displayed than in the rapid increase and development of the inexhaustible resources of our country—in the construction of bridges, roads and canals and in almost everything substantially useful to the present and future generation. These improvements form the solid glory of the nation—a proud column of fame around which the blessings of posterity will gather. Other nations may boast of their victories—they may tell us of thousands slain in fighting the battles of ambition, or to slake the thirst for revenge and of the extent of their conquests, we can be proud of less sanguinary fame in making the wilderness to bud and blossom and in diffusing those substantial blessings which make a people prosperous and happy. "Agriculture was the first employment given

to man by his Maker and gardens must bloom before virtue blossoms." It has been said that nations like individuals, have their youth, maturity and decay. We are in the full vigor of youth—an infant Hercules—the "proudest Empire of Europe is but a bauble to what America may—must be." The rapid changes which are taking place, the sudden transition of the wilderness into cultivated fields, the rapid increase in population, the dissemination of useful and practical knowledge among the people, and the advancement of the arts and sciences, all have outstripped the calculations of the most visionary and devoted admirer of the country and are sure guarantees of the wisdom and stability of our social compact. A foreigner would with reluctance believe that a country so well improved as Ontario could have been a wilderness thirty years ago. The change is truly astonishing. The work is going on. Today we see a trackless wilderness, tomorrow the forest has disappeared,—the smiling cottage, the golden harvest and the busy hum of industry have succeeded to solitude and desolation. But a few years ago the passing traveler might have looked in vain for 'the smoke that so gracefully curled around a green elm' as a signal of a cottage in which he hoped to meet the cordial greetings of hospitality. Here on the Banks of the Genesee River, the poor Indian "whose soul proud science never taught to stray, far as the solar walk or milky way" held his infernal orgies, here he sat in counsel and sang the war song—here the faggot pile was erected, the victim bound, the torch applied—and here the tortured soul amid all the horrid cruelties that savage ingenuity could invent, breathed out his existence invoking vengeance upon his tormentors. The scene is changed, the few red men that remain, the mere shadows of what they have been, gain a scanty subsistence and wander about like the ghosts on the banks of the fabled Stix.

Like all new countries which are fertile the Genesee country was unhealthy and the exaggerated and frightful stories were told, for sometime prevented its rapid settlement. The prejudices then excited are even at this time not entirely done away, although it has long since become a remarkably healthy portion of the state, and the counties of Ontario and Genesee are surpassed by none for fertility of soil and salubrity of climate. In fact, the whole country from Utica to Buffalo is incomparably fine—it comprehends every variety of soil, produces grain and fruit in abundance and of the greatest perfection, has a climate neither enervating by intense heat nor cramping the mental energies by intense cold, a sufficient degree of industry is required to prevent luxury and effeminacy and leisure granted to expand the soul, without which the

the banks of the Erie Canal at Lyell Street. Some of the bridges built later were swept away by floods and had to be rebuilt. The old Carthage bridge, completed in 1819, at the site of the present Driving Park Avenue bridge, was described as one of the wonders of the world with one arch, its floor 196 feet above the water. It fell fifteen months after completion, at a great loss to the city as the builder had given but one year's guarantee.¹¹

Rochester was incorporated in 1817 and in 1822 its name was changed to Rochester although it was not incorporated as such until 1834. It was settled in 1812 and was formed as a village from the townships of Brighton and Gates and named after Colonel Nathaniel Rochester of Maryland, one of the three owners of the One Hundred Acre Tract.¹² Some of Rochester's neighbors were settled earlier, Pittsford in 1790 and Charlotte in 1793.* Hanford¹² has given us some interesting information regarding the founding of some of the surrounding villages. Brighton was named after the English city of that name and settled in 1814. Chili, whose first resident, James Morgan, a Revolutionary soldier, came there in 1792, was probably named after Chili, South America.

Clarkson was settled in 1819 and Gates in 1802, the latter first being called Northampton and renamed a little later Greece. It was formed in 1822 and it is quite likely that it was named after the Kingdom of that name as it had a revolution the year before. Hamlin was created much later (1852) and was called Union until 1861 when it was rechristened in honor of Hannibal Hamlin, Lincoln's vice-president. Henrietta called after Henrietta Laura, Countess of Bath, was settled in 1818. Mendon, probably named after Mendon, Massachusetts, was created in 1812 and in 1817 came Ogden,

so-called in honor of William Ogden of Parma. Carthage was once a flourishing village situated at the lower falls of the Genesee and was named after the ancient city of that name in Africa. The word itself means "New Town" and this village was gradually absorbed into Rochester. Hanford's Landing was another important village of that time which no longer exists. It was across the river from Carthage, at the head of navigation in that stream. Its first title was King's Landing, named for Gideon King, an early settler but renamed in 1910 when the Hanford's five brothers and two sisters opened a store there and later a hotel and did a thriving business.

Rochester was once termed the "City of Mud in a Dismal Swamp." It is difficult to picture our Rochester of today, known widely as a city of natural beauty, as having sprung out of such an unattractive region. Turner tells us that in 1800 Wheelock Wood built a sawmill which operated for only one season as the workmen all came down with fever and the mill had to be abandoned. At the time that Monroe County was formed, Rochester was objected to as a county seat and it was derisively remarked that there were better places than "Shingletown," meaning Rochester, for the county seat.

Rochester had a mushroom growth. Charlotte, situated on the Lake at the mouth of the river had flourished earlier but now settled down to a minor place and Tryon, a town of which much had been expected, died out entirely. By 1816-17 Rochester had become an important wheat market and in 1838 it was said to be the largest flour market in the world. In 1830 it ranked twenty-first in size in the United States. The *Gazette* which we have quoted before, stated in September, 1820

Our village for a few weeks past has literally been filled with strangers who all express their agreeable surprise at finding so large and pleasant a village where five years ago there was scarcely an inhabited building. The village contains about 1,700 inhabitants and is second to none west of Utica either in commercial or manufacturing business. There were four "flouring" mills in the place and when Congress shall in their wisdom see fit to reanimate the manufacturing interest of the country, the enterprise of the inhabitants of Rochester will soon develop itself in lining the banks of our river with manufacturing establishments.

* "When Buffalo, Batavia, Canandaigua, Geneva, Palmyra, Penn Yan, Bath, Genesee, Caledonia and Leroy had become considerable villages and local business had begun to center at Pittsford, Penfield, Victor, Lyons, Vienna, Manchester, East Bloomfield, Lima, Avon, Dansville, Angelica, Warsaw, Attica, Lewiston, Oak Orchard, Gaines, Clarkson, Parma, Charlotte, Handsford Landing and Scottsville, sufficient for clusters of little stores, machine shops and dwellings, at Genesee Falls, now known as Rochester, were but a few rude dwellings and a rude mill with less than six families" (Turner).

conditions under which they had to labor. They came to a sickly land crying for medical help. Dr William W Reid, a pioneer physician said "

The name Genesee Country was formerly associated strongly in Eastern minds with ideas of sickness and death. Those remaining behind in New England thought it a valley of bones, a permanent burying place for those loved friends and relatives who were tempted to settle in this then newly opened territory. Intermittent fevers, remittent fevers and cholera morbus carried away to an early grave many early settlers. Rochester was at that time a small village, its streets ungraded and undrained, the forest encroaching upon its suburbs, the stumps of recently felled trees mingling with the buildings, the soil a deep vegetative mould that had been accumulating for ages and covered with decaying matter—what wonder that malaria and malaric disorders should prevail, that ague at its worst and most diversified forms, should abound?

John Maude²⁵ visited this part of the country in 1800 and in his diary he wrote during August that he had not yet seen a case of intermittent fever or any other fever in the Genesee Country, although the insalubrity of the region was proverbial because of fever and ague termed the Genesee Fever. His friends had earnestly cautioned him against spending even one night in the vicinity of the Genesee and one of his acquaintances had given him some doses of St. James' Powders to take with him but he had no occasion to use them. Again in October, he spoke of the unjust reports regarding the malignancy of the Genesee Fever but added that an old schoolmate, Mr Dennison of Nottingham "would have been added to the list of its martyrs, had not the benevolence of Captain Williamson interfered." Many others of his acquaintance, he stated, had been seized with the fever, indeed few of them escaped.

The *Rochester Telegraph* on September 21, 1819, reported that in seven weeks four in one family had died of the fever prevailing on the shore of Lake Ontario. Two weeks later the paper contained a denial of the report that malignant fever prevailed in Rochester but admitted bilious remittent fevers were frequent, that nine out of a population of 1,200 to 1,400 died within twelve months, four of them being infants and two of the adults died of pulmonary complaint. "It has been sickly at the mouth of the Genesee River, Sandy

Creek and so forth," the writer said, "however we understand the sickness is abating." At the same time fever was reported in New York City and it was stated that the infected district was fenced in and in order to enter, permission must be obtained from the Board of Health. We cannot tell, therefore, whether the sickness in Rochester that year was the usual so-called Genesee Fever or whether it was a state-wide infection. In September 1820, just a year later than the above was written, the *Telegraph* remarked on the healthy situation of the village, the salubrity of the climate, and the fertility of the circumjacent country.

A few years later, the same paper stated that reports were being circulated erroneously regarding the sickness in this village and causing much alarm abroad. It had been reported that seven or eight died each day and that the inhabitants of adjoining towns did not venture to approach the "infected district." The readers were assured that the general good health of the place equalled that of any other having 40,000 inhabitants. "During the second week in this month when the weather had become extremely hot and dry, we had considerable rain which favored the progress of the cholera morbus, several cases and five or six deaths occurred within a few days but we have heard of only one new case for the last ten days." The following week one case was reported but many children had died of bowel complaint.

By 1828 the fevers became mild and infrequent, and seldom fatal. The *Telegraph*, stated in July of that year

Notwithstanding the many cases of fever and ague early in Spring, it has been remarked to us by several physicians that never within their knowledge was Rochester so healthy as it has been for a couple of months and is now. The coolness of the weather seems to have had a very salutary effect. The fact that our population large as it is, is almost wholly composed of persons in the prime of life,—for few of the aged or infirm would be tempted by the hope of gain, to leave their Eastern homes for this new field of enterprise,—also furnished a reason for the small proportion of deaths in this place in comparison with the mortality in older places of similar size.

Yet, as Dr Reid informs us, as wealth, refinement, luxury, and ease increased

noble and disinterested traits of character would be lost in the mercenary and selfish. But the western part of the state of New York is not more distinguished for wealth and fertility of the soil than the wonderful and attractive variety of its scenery. Our own little village is not the least attractive of the many objects of curiosity that abound and we venture to say, the ruins of Carthage Bridge, the three falls of the Genesee River, together with the water works of this village form a more beautiful, wild, romantic and useful display of nature and art combined than can be found in the world. Why those who have taken it upon themselves to describe the many natural curiosities of the country have until recently passed the falls of the Genesee River in silence, we cannot explain, unless the powerful interest which the Niagara Falls in this vicinity excite, like Aaron's rod, swallowed up the rest. It is true, neither of the falls in this vicinity will compare in magnitude with the Niagara, there is not that thought-suspending, overpowering grandeur, that awful magnificence whose frown terrifies the glance its magnificence attracts, that makes "the soul shrink back upon itself and startle at destruction," but all combined they form an attraction little less powerfully interesting.

We have quoted this editorial thus in its entirety, for two reasons *first*, because it gives us a vivid picture of early Rochester and *second*, because the culture shown by the writer is greater than we might expect of that time in Rochester. The publisher and editor of the paper and perhaps, the writer of the editorial, was Augustine F. Dauby.

Let us digress for a short time to quote other items from the early Rochester papers. So few take the time to read these old newspapers that these interesting bits remain unknown. The *Telegraph* in 1823 contained an article on Boerhaave, famous physician and scholar, who, the article states, made a will ordering that all his books and manuscripts should be burnt with the exception of one large volume with gilt-edged leaves and silver clasps. The "physical people," meaning no doubt, the unwell, flocked to Leyden and beseeched the executor to disregard the order. Boerhaave's effects were sold at auction and a German count, believing that the gilt book "contained the whole arcanum of physis" purchased it for 10,000 guilders. Upon opening his new purchase, he found all the pages blank except the first one upon which was written "Keep the Head cool, the Feet

warm and the Body open and bid defiance to the Physician." Another delightful piece of news is given in that paper the same year, this time regarding Dr. Benjamin Franklin. It states, "The directors of the Athenaeum have lately purchased a large number of pamphlets which were formerly the property of this philosopher. Many of them are particularly valuable on account of the marginal notes which they have received from his hand. Some are of an amusing cast,—on the first page of a collection of extracts from the registry of the faculty of medicine in Paris, there is a vignette with this observation in the handwriting of Dr. Franklin, "It is remarkable that the arms of the faculty above should be three ducks with herbs in their mouths to prevent their pronouncing the motto, 'Quack, Quack, Quack.'"

Still another account in that paper a month later regarding Franklin is specially interesting and touching. It states that Dr. Franklin wrote on May 18, 1787 to his friend, C. Whately, Esquire

You are now seventy-eight and I am eighty-two. You tread upon my heels but though you have more strength and spirit, you cannot come up with me until I arrive at my journey's end, which must be very soon, for I have grown so old as to have buried most of the friends of my youth and I now often hear persons whom I knew when children, called Mr. Such-a-one, to distinguish them from their sons, now men grown and in business, so that by living twelve years beyond David's period, I seem to have intruded myself into the company of posterity when I ought to be abed and asleep. Yet had I gone at seventy, it would have cut off twelve of the most active years of my life, employed too in matters of the greatest importance, but whether I have been doing good or mischief, is for time to discover. I only know that I intended well and hope all well.

Those having the courage to toil through the old Rochester newspapers will be rewarded from time to time for all their labor by the discovery of such precious bits. Many of them, not being medical in character cannot be included here.

The question may be asked, what has all that has been here written regarding early Rochester, have to do with the medical history of Monroe County. We have given this brief outline of the establishing of Rochester and Monroe County in order that we may visualize the kind of country to which our early physicians came and the

conditions under which they had to labor. They came to a sickly land crying for medical help. Dr William W Reid, a pioneer physician said " "

The name Genesee Country was formerly associated strongly in Eastern minds with ideas of sickness and death. Those remaining behind in New England thought it a valley of bones, a permanent burying place for those loved friends and relatives who were tempted to settle in this then newly opened territory. Intermittent fevers, remittent fevers and cholera morbus carried away to an early grave many early settlers. Rochester was at that time a small village, its streets ungraded and undrained, the forest encroaching upon its suburbs, the stumps of recently felled trees mingling with the buildings, the soil a deep vegetative mould that had been accumulating for ages and covered with decaying matter—what wonder that malaria and malaric disorders should prevail, that ague at its worst and most diversified forms, should abound?

John Maude¹³ visited this part of the country in 1800 and in his diary he wrote during August that he had not yet seen a case of intermittent fever or any other fever in the Genesee Country, although the unsalubrity of the region was proverbial because of fever and ague termed the Genesee Fever. His friends had earnestly cautioned him against spending even one night in the vicinity of the Genesee and one of his acquaintances had given him some doses of St. James' Powders to take with him but he had no occasion to use them. Again in October, he spoke of the unjust reports regarding the malignancy of the Genesee Fever but added that an old schoolmate, Mr Dennison of Nottingham "would have been added to the list of its martyrs, had not the benevolence of Captain Williamson interfered." Many others of his acquaintance, he stated had been seized with the fever, indeed few of them escaped.

The *Rochester Telegraph* on September 21, 1819, reported that in seven weeks four in one family had died of the fever prevailing on the shore of Lake Ontario. Two weeks later the paper contained a denial of the report that malignant fever prevailed in Rochester but admitted bilious remitting fevers were frequent, that nine out of a population of 1,200 to 1,400 died within twelve months, four of them being infants and two of the adults died of pulmonary complaint. "It has been sickly at the mouth of the Genesee River, Sandy

Creek and so forth," the writer said, "however we understand the sickness is abating." At the same time fever was reported in New York City and it was stated that the infected district was fenced in and in order to enter, permission must be obtained from the Board of Health. We cannot tell, therefore, whether the sickness in Rochester that year was the usual so-called Genesee Fever or whether it was a state-wide infection. In September 1820, just a year later than the above was written, the *Telegraph* remarked on the healthy situation of the village, the salubrity of the climate, and the fertility of the circumjacent country.

A few years later, the same paper stated that reports were being circulated erroneously regarding the sickness in this village and causing much alarm abroad. It had been reported that seven or eight died each day and that the inhabitants of adjoining towns did not venture to approach the "infected district." The readers were assured that the general good health of the place equalled that of any other having 40,000 inhabitants. "During the second week in this month when the weather had become extremely hot and dry, we had considerable rain which favored the progress of the cholera morbus, several cases and five or six deaths occurred within a few days but we have heard of only one new case for the last ten days." The following week one case was reported but many children had died of bowel complaint.

By 1828 the fevers became mild and infrequent, and seldom fatal. The *Telegraph*, stated in July of that year

Notwithstanding the many cases of fever and ague early in Spring, it has been remarked to us by several physicians that never within their knowledge was Rochester so healthy as it has been for a couple of months and is now. The coolness of the weather seems to have had a very salutary effect. The fact that our population large as it is, is almost wholly composed of persons in the prime of life,—for few of the aged or infirm would be tempted by the hope of gain, to leave their Eastern homes for this new field of enterprise,—also furnished a reason for the small proportion of deaths in this place in comparison with the mortality in older places of similar size.

Yet, as Dr Reid informs us, as wealth, refinement, luxury, and ease increased,

"consumption gained ascendancy whereas in 1804 when fevers were raging, pulmonary consumption was almost unknown"

Other writers mentioned the early unhealthy conditions of this county. Dr Alexander Coventry, president of the New York State Medical Society in 1824 cited the Genesee country as an example of unhealthy wooded countries where the decay of deciduous trees with rotted leaves, cause gases poisonous to humans and said that from 1792 to 1795 inclusive, the proportion of the sick to the well according to population, was much greater in the Genesee country than in large cities, even in the seasons when malignant fevers prevailed.

Peck in his history of Rochester writes of 1812 with its cases of pleurisy and "pneumonia typhoids" followed by a formidable epidemic in spring and fall. Two years later came another but less severe epidemic followed in 1815 by an epidemic of dysentery. The *Rochester Advertiser* in 1830 reported that only one percent had died in the village, eighty-six were children under ten, twelve adults over sixty, and thirty-one deaths were caused by consumption and only twenty-five of fever. The writer added, "Few places of 11,000 or 12,000 can exhibit for an equal space fewer cases of mortality."

It is surprising to read in these early newspapers the frequency of the appearance of hydrophobia in Rochester and its vicinity. In 1831, the Board of Trustees of the village found it necessary to pass an ordinance prohibiting dogs to run at large within

the village and a notice was printed in the paper thereof and a penalty of ten dollars threatened. The notice added that anyone preferring a complaint of dogs at large and presenting witnesses, would receive half of the penalty enacted. Many articles appeared in the papers containing remedies for hydrophobia. In the following year, mention of the horrors of the disease appeared again in the newspapers and it was stated that two men and a child had been bitten in the village. One of these men had his bitten toes amputated to prevent spread of the disease. The citizens were again warned to restrain their dogs to keep children away from them.

Cholera epidemics played great havoc in this region in 1832, 1834, 1849, and 1852. We will discuss them at length a little later. Let us leave the consideration of sickness in the village for a time and learn something of the early practitioners.

Chapter II

The Early Physicians and Druggists and General Health Conditions

Genesee fever Epidemics dysentery cholera First physicians Drugstores News paper advertisements, Epidemic reports of smallpox, cholera, First medical schools

The first physician to come to Rochester was Dr. Jonah Brown in 1813 at the age of twenty-two.¹ It is reported that a panther almost clawed him while he was visiting a patient near the rapids and that he "sang to keep the critter off." This kindly physician acted as doctor, nurse, and cook in stricken families. Lodgings then were impossible to obtain and during the winters of 1813-14, he slept on a floor with his saddlebags for a pillow and a horse blanket for covering. Sometimes he was called at night to Stone's tavern and there

had difficulty passing through the bar-room because the floor was packed with sleepers. It is said of this early physician that he finally became wealthy and in 1854 was worth \$100,000.00. Dr. Orrin Gibbs was second to arrive to practice medicine here. The first surgeon, for medicine and surgery were then practiced usually separately, was Dr. Simeon Hunt, who settled in Greece in 1812. It is told of this surgeon that Hamlet Scrantom rode on horseback to his home to get him to attend his daughter and Dr. Hunt performed a successful op-

eration upon the girl which required two hours to complete. Dr Hunt practiced in this vicinity for forty or more years, settling in Greece as successor to Dr Zaccheus Colby, a surgeon of Stone's Dragoons in the War of 1812. Another practitioner was Dr John G Vought, whose name appears so frequently in the advertising columns of the papers. Dr Levi Ward, too, was an early settler, coming to Rochester in 1817 and "was one of the first to break into the wilderness north of the old Buffalo Road." He had settled with his large family in LeRoy in 1807 and in 1812 commanded a company of soldiers raised in Bergen, which however, never saw action. Dr Ward transported the weekly mail, Turner tells us, between Caledonia and Charlotte and the postage received was his remuneration. The same writer quotes Dr Abel Baldwin, another early resident of LeRoy, as saying, "When I moved into the country in 1811 with my family, we were ferried over the Genesee River at Rochester. The Ridge Road was cut only wide enough for a wagon track and the streams were crossed by means of log bridges."

Dr Fred F Backus was the son of Azel Backus, D D, president of Hamilton College in 1813. He graduated from Yale at the age of nineteen in 1813 and came to Rochester three years later, afterwards becoming a leading citizen, acting as president of the Monroe County Medical Society in 1822, first alderman of Rochester in 1834 of the Third Ward, which included all inhabitants on the west side of the Genesee River and south of the Erie Canal and Buffalo street.²

In 1843, Dr Backus became a member of the State Senate. There is much that could be told of this eminent citizen but as we are concerned with the history of organized medicine rather than with that of individual practitioners, his story must be omitted here. Dr John B Elwood, another physician of note, was born in 1792 and came to Rochester in 1817, became treasurer of the village in 1827, later postmaster, then mayor. Dr Azel Ensworth was another eminent man, arriving in 1816 and living to over ninety years of age.

Dr Hartwell Carver was a prominent physician of Pittsford, born in 1789, a descendant of John Carver of Mayflower fame and graduating from Yale in 1816 with A.M. and M.D. degrees, then settling

in Pittsford in April 1816, in debt to the amount of two thousand dollars for his education. Evidently his practice was extensive and remunerative, for in a year he cleared \$1,500 00 in his practice, a large amount for those days. He entered business six years later and retired three years after (1825). He spent his winters in the south and practiced medicine during the summer months in Monroe County until 1831 when he went to Europe for a year's study, then practiced extensively in Rochester.¹

The following are some of the early practitioners and where they lived

Brighton—Dr O E Gibbs, 1814, appointed Surrogate of Monroe County, 1823

King's Settlement, at mouth of the Genesee River—Dr Zaccheus Colby, and Dr Sylvester Atkinson

Riga—Dr John Darling, succeeded by Dr Richard Dibble.

Ogden—Dr Gibbon Jewett, practiced many years, died 1823

Parma—Dr John D Higgins, Dr John Scott.

Pittsford—Dr John Ray, Dr Daniel Rood, succeeded by Dr Achilles, Dr G Smith and Dr Hartwell Carver

Mendon—Dr Knickerbocker, later of Rochester, succeeded by Dr Harvey Allen.

East Mendon—Dr William Brown, later of Pembroke.

Rush—Dr Alexander Kelsey, 1811, Dr Socrates Smith, 1812

Scottsville—Dr Guthrie, Dr S S Brown, succeeded by Dr Freeman Edson, 1814 who died 1883 after a distinguished life.

Mumfords—Dr Power

An interesting case of Dr Joseph Camp, a student of Dr Carver of Pittsford, is related in the *Rochester Telegraph* of September 1822. It is a testimonial from a Henry Gale of Perinton, who said that Dr Camp had cured Mrs Gale of a cancer by applying for three months, an original preparation, a vegetable production, which "caused the cancer to come out of her body with all its many roots."

Dr Abel Baldwin came to Clarkson in 1811 and practiced but a few years, opening a public house at 1815 at Murry Corners. Later he built the first tavern house on the Ridge Road and retired to become a farmer in 1825. Dr Azel Ensworth who came to Rochester in 1816 opened his home to the first court hearing of the County of Monroe.

It is through careful scanning of early newspapers of Rochester that we learn of

many early physicians and also of the early pharmacists and other purveyors of medicine. In a weekly called the *Rochester Telegraph*, we read in an 1820 issue that Silas Smith's Cash Store carried drugs and medicines as well as groceries and dry goods and that Everhard Peck, a pioneer printer, publisher, and bookseller, offered in addition to various books of many sorts, twenty-nine medical books at a price of \$1 00 to \$4 50 per volume. Except for cough drops and such simple remedies, he carried no drugs but he advertised with high recommendations, certain medical journals, the principal one being the *American Journal of Medical Science*, a publication which has been continued to this day. It was Everhard Peck's son, William F Peck, a semi-invalid who spent his life on crutches, to whom we are indebted for most of our knowledge of the history of early Rochester.

Dr Fred F Backus, the leading physician of his time in Rochester, whom we mentioned before, had the first village drugstore, his advertisement appearing in November 1818. He added a soda fountain the following year and at the end of the year his store was burned in a fire which consumed several buildings. He reopened in February 1820. The next drug store was that of Mr William Pitkin, at 19 Buffalo Street, his advertisement appearing first in December 1820 in the *Telegraph* and continuing to occupy many columns of newspaper space until 1852 when Paine and Swan, former clerks of Lansing Swan, a druggist opening his store in 1852, purchased the old stand. These young men had previously purchased the Swan store. Later, C F Paine secured entire interest in the store which later became known as the Paine Company Drugstore, which remains today. The Post Drugstore, another old store still remaining in Rochester, was opened in 1835.

The old druggists were evidently prominent men, for Pitkin became mayor of Rochester and Swan while not elected, was honored by being nominated for that office. We find Caleb Hammond opening a drugstore, advertised on January 16, 1821, a little more than a year after Pitkin's store was opened. The drugstores frequently carried half-column advertisements enumerating the merits of a favorite patent medicine, claiming cures for all ills, Dr

Backus' store no less than the others. For example, in 1822 he advertised some "anti-dyspeptic pills," 100 for one dollar, which would cure "irregularity of bowels, obstinate costiveness, violent headache, yellowness of the eyes, acidity of the stomach after eating, flatulence, bitter taste in the morning, fetid breath, drowsiness after dinner, debility, lassitude, emaciation, depression of spirits and piles." Peck ran a lengthy description of the curative powers of Anderson's Cough Drops while Pitkin advertised a Vegetable Pulmonic Detergent. There were at that time four drugstores, Backus', Elwood and Coleman's, Hammond's, and Pitkin's. A Doctor Harral had a drugstore at the corner of Buffalo and Carroll Streets, conducting it with his practice and advertised patent medicine extensively. We read with amusement the following article in the *Rochester Telegraph* in 1828.

Dr Harral, formerly of this village, has become a rival of Dr Scudder at New York in the insertion of artificial eyes. He lately repaired in this way, the frontispiece of a Westphalian soldier who lost his eye at the battle of Smolensko. The *New York Courier* says that the Westphalian is so delighted with his acquisition that he is determined upon courting a widow at once. To do this, a man should have both his eyes open and so has Ferdinand. Dr Harral imports these artificial eyes from Paris.

Hitchcock in 1822 carried an advertisement offering drugs and medicines along with dye stuff, paints, oils, wines, liquors, and groceries "at a small advance on wholesale prices." Pitkin in the same issue stated that he sold dye stuffs, paints, drugs and medicines, rifles and musket powder on better terms than could be obtained from Utica or Albany and that he would accept country produce in exchange. Dr Richard Dibble, a druggist on Carroll Street, advertised in 1829, "It is not intended that the druggist business shall interfere with the practice of medicine. All professional calls will be promptly attended to." We note that competition in selling merchandise came early in Rochester. In January 1823, the paper contained an advertisement of a patent medicine for sale by the following

Rochester	William Pitkin, G Hitchcock
Penfield	G Penfield
Greece	B King

Charlotte	Bushnell and Company
Oak Orchard	Dr Stevens
Chili	William Pixley and Company
Webster's Mills	I Webster
Avon	J Pierce
Scottsville	W H Hanford
Churchville	H Hall
Parna	William McKnight

We cannot help being impressed by the enterprise of the patent medicine makers in spreading their products in those days of difficult travel and their appreciation of the benefit to be derived from advertising. Indeed, so much space was devoted to patent medicine advertising that much of the financing necessary for publishing the newspapers must have been obtained from that source.

Another early custom which we note with interest was the insertion of notices, or cards, in the newspapers by physicians newly arrived in town. These advertisements ran for a number of issues and were usually little more than a notice that the new doctor was ready to serve any patients presenting themselves. One appeared in the second issue of the *Rochester Telegraph* on July 14 1818, in which Dr Hartwell Carver "informs the public that he has settled himself as a physician and surgeon at Murry's Four Corners where he will attend to all calls both in the practice of physic and surgery and particularly to all operations in surgery." This notice ran for three issues. Doctors Elwood and Colman advertised May 13, 1819 that they would vaccinate with "Genuine Kine Pox Matter" and that "emigrants recently arrived and indigent families will be vaccinated gratuitously by calling at our office." From reading this early notice we know that when Rochester was only two years old as an incorporated village, it had not only its poor but its physicians ready to care for them without remuneration. We find no other profession offering free service. Does it not seem strange that in a changing world, with customs, beliefs, and ideas altering with the years, that the altruism of the medical men has endured.

Two months after Elwood and Colman's advertisement appeared, Dr Vought offered free vaccination to the poor and a year later he entreated the poor to come and be vaccinated. Evidently that was considered oversolicitous, for Elwood and Col-

man inserted a notice offering pure kine pox vaccine "with which we offer, not beg, to vaccinate families." Not only was it a custom at that time for physicians, lawyers, and dentists to insert a notice in the newspapers mentioning the opening of an office in the village but also notices appeared asking the debtors to settle their obligations. We find such notices appearing frequently and expressed in rather urgent language, for at that time debtors were jailed for unpaid debts.

From the newspapers we learn of the epidemics of the time. On February 17, 1827, the *Rochester Observer* reported eight deaths from smallpox the previous week, seven the week before, and eleven the week before that. As an illustration of the horror in which this dread disease was held and the ignorance concerning it, the *Gazette* in 1820 gave this humorous story. A man was burying a smallpox victim in a cemetery when a woman approached him and objected "You can not bury him here beside my husband," she cried, "he never had it." In 1830 another Rochester paper, the *Advertiser*, stated that this "loathsome disease no longer affects the village," adding that there were only three or four genuine cases and seven or eight modified cases and no deaths. In 1833 the same paper reports a new outbreak in the village, stating that the Board of Health had commissioned two physicians, Dr Reid and an assistant, to go from house to house through the town. It took two months for the two doctors to do this work, having to repeat their visits frequently in order to find the people in. They vaccinated all but about sixty people, a few of whom had suffered from the disease and the rest objected to vaccination. Dr Reid warned the public that unless all were vaccinated, the village could not be freed from the pestilence.

We mentioned cholera as a great destroyer in early Rochester life. In the first epidemic, that of 1832, a Board of Health was appointed, consisting of Dr Ward, Dr Coleman, Dr Reid, Mr Everard Peck, and Mr Asbek W Riley. Dr MacPherson of Scottsville added his services to the cholera victims in Rochester. Dr Colman went to Montreal to study the treatment of the disease there. The first case of cholera, according to Peck's history, occurred in a tavern on St. Paul Street below Court

Street (now South Avenue) on June 22, 1832 Mr Riley attended this man but he died the same day and was buried in an old burying ground on Monroe Avenue, the present site of Monroe High School All the cholera victims of that year were buried on that spot During July and August while the epidemic raged, business and travel almost ceased Camphor, a preventive medicine of the time, was much in demand and rose in price from thirty cents a pound to several dollars Brandy and calomel, too, were favorite remedies A temporary hospital was erected in the western part of the city on the banks of the Erie Canal Mr Riley of the Board of Health was the hero of the time, caring for the sick and burying the dead He is said to have placed eighty of the 118 victims in their coffins

A third scourge visited Rochester in 1849 and this time claimed 160 victims Again in 1852 came another epidemic and a building on High Street, later named Caledonia Avenue, was used as an emergency hospital with Dr Richard Gundry in charge A lengthy report of this visitation of cholera was written by Drs E M Armstrong, D M Dewey and Hiram Baker We learn that there were 700 cases in that awful epidemic and that 420 persons or one per cent of the population died Three of the victims were physicians, Dr J J Treat, Dr William Bell, and Dr D C Phelps Dr Mott who took an active part in checking the epidemic of that year, said that there was such a fear of the disease that on crossing Main Street at noon one day that summer, he saw not a soul on it.

Just one case of smallpox appeared in 1863 but in 1872 there were 150 cases, twenty-eight of which were fatal In March of that same year there was an outbreak of cerebrospinal meningitis with twenty-eight deaths In 1882 there came another smallpox scare but the Board of Health "pre-

vented it by prompt action" We find a similar statement away back in 1820 in the *Rochester Telegraph* which states that Mr Thaddeus Spencer of the village upon his return from a visit in Canada, had smallpox but "prompt and effectual measures prevented contagion" and requested that Rochesterians dogs not be permitted to run at large and communicate smallpox The newspaper of the following week contained a notice from the Board of Health that a Stebbins baby, living in the same house with Mr Spencer, had contracted smallpox It stated that the baby had been repeatedly vaccinated without effect and it was not certain but what the sickness was due to vaccine The public was asked to keep away and the report was signed by the Commissioners of Health, Dr Levi Ward Jr, M Brown, Jr, and H R Bender It is in the newspapers of that same year in which we read so many advertisements offering pure lime pox vaccines for sale. One by Stephen B Bartlett offered a certificate from respectable physicians that the vaccine was genuine In keeping with the publicity given to the use of vaccines that year, we note with interest that a recommendation was made at the New York State Medical meeting in Albany in 1829, that the Society recommend to the Legislature a law establishing a State Vaccine Institution

We have been considering general health conditions in the early life of the village, the personnel of its medical men, the sale of drugs and medicines, and the epidemics which swept through the village in those days Let us next turn to organized medicine in its initiation in Rochester

(To be continued in the next issue)

MEDICAL GOLF NOTE

"You are senile, old man," the young golfer said,

"And you swing like an awkward old cow,

Yet your score is consistently over my head,
Won't you tell me the why and the how?"

"In the days long ago," the old man answered back,

"How I practiced through sunshine and storm,

But now I step up and just hit her a whack,
And I don't give a damn about form"

—C G Farnum, M D, *Peoria Medical News*

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested.

Delaware County

NO "OLD AGE SECURITY" plan seems needed for Delaware county doctors. Dr J A Holley, of Walton, celebrated his eighty-second birthday a few weeks ago, had a dinner party at his home, and, according to the local paper, "is still active in the practice of his profession and keenly interested in the affairs of the community." And a few miles away, says an Oneonta paper, "Serving three vicinity communities for more than sixty-two years, Dr Frederick N Winans of Franklin has the unique distinction of being the oldest medical practitioner in this section, both in age and in years of service. Now in his eighty-fifth year, Dr Winans continues to serve as capably as he did when he first opened an office in Cobleskill in 1874.

"The veteran physician is as active as a man half his years and a midnight call in the dead of winter is as cheerfully answered as a half century ago.

"The doctor was married for the second time last spring."

Errie County

UPON RECEIVING A COMMUNICATION from Dr Winfield Ney, of New York, urging that the doctor's free contributions in medical service should be deductible in income tax returns, the editor of the Errie County *Bulletin* recalls a calculation made by Dr John L Hoffman, of the County Economics Committee, that free medical and surgical services by Errie county practitioners amounted for the year 1933 to a total of \$916,612, for 1934 to \$994,477 and for 1935 to \$1,114,682.

Franklin County

DR. DAISY VAN DYKE of Malone was elected president of the Franklin County Medical Society at a meeting held Oct. 21 in Malone. She succeeds Dr Edward N Packard.

Other officers elected were Dr D M Brumfiel Saranac Lake, vice-president, and Dr F F Finney, Malone, secretary and treasurer.

Dr Russell B Cecil of New York was the principal speaker, his subject being the diagnosis and treatment of pneumonia.

Kings County

AFTER CELEBRATING ITS first birthday,

the Bushwick District Health Center, a city enterprise, at 186 Grove St., Brooklyn, can point to several important accomplishments during its initial year, according to Dr Anna E. R. Robinson, district health officer.

Reducing the locality's diphtheria cases from the highest in the city to one of the lowest was an outstanding activity of the center's first year program, Dr Robinson said.

"During 1934, the Bushwick Health District, with about 3 per cent of the population of the entire city, had 12 per cent of all cases and deaths from this disease," she said.

"Bushwick Health District formerly led in the number of cases of diphtheria in the city but today it is one of the lowest, because of the intensive health education campaign launched by the center."

As against 139 diphtheria cases, with thirteen deaths, in 1934, and fifty cases, with four deaths, in 1935, there have been only twenty-four cases and no deaths for the first nine months of 1936 in that section, Dr Robinson added.

A marked decrease in the district's infant mortality has also been noted, Dr Robinson reported.

THE MEETING OF THE Bay Ridge Medical Society on Nov 10 was devoted to a discussion of cardiac disease. A paper on "Cardiac Edema" was presented by Dr John Hamilton Crawford, F.A.C.P., cardiologist at the Kings County Hospital and chief of the cardiac clinic of the Long Island Dispensary.

Madison County

DR. A J ZAIA of Oneida was elected president of the Madison County Medical Society at the annual meeting held Oct 27 at Oneida. He succeeds Dr Robert L Crockett.

Other officers named for the ensuing year include Dr John D Boyd, Chittenango vice-president, Dr Lee S Preston, secretary, reelected, Dr H S Germer, Canastota, treasurer.

Dr Zaia is delegate to the State Medical convention to be held next spring. Delegate to the fifth district branch is Dr Crockett.

Papers were given by Dr C C. Curtiss,

Syracuse, "Appendicitis in Childhood," Dr Ellery G. Allen, Syracuse, "Pernicious Anemia," and Dr Crockett, "Hematology." Lantern slides were shown to illustrate the talk given by Dr Allen.

Preceding the meeting, members of the Society and their wives met for dinner at 6:30.

The Women's Auxiliary of the Madison County Medical Society was organized, with Mrs. Otto Pfaff chosen as temporary chairman. The business meeting followed a dinner with members of the medical group.

A constitution and set of by-laws are yet to be drawn up and officers are to be elected. Mrs. Richard Cuthbert of Canastota is temporary secretary. Officers will be elected at the next meeting, December 10, at Oneida, at which time a Christmas party will also be held. Members of the Medical Society will be guests.

Committee for the constitution and by-laws is headed by Mrs. George F. Mills. Mrs. Charles Earl was appointed chairman of the nominating committee.

Arrangements for the December meeting are in charge of Mrs. Eugene W. Carpenter, Mrs. E. L. Finley and Mrs. Howard Beach.

Monroe County

THE UNIVERSITY OF ROCHESTER'S School of Medicine and Dentistry was host to doctors of Western New York, and to its own alumni, at a three-day post graduate medical conference on Nov. 5-7.

Lectures, demonstrations and research exhibits, revealing advances in medical science were included in the program.

THE DANGER OF LETTING medical bills run for years is being illustrated in Rochester, where a physician is trying to collect a bill for \$19,700, due for medical treatment over a twenty-four year period, from the estate of Rudolph Speth, late treasurer of the Eastman Kodak Co. The administrators are trying to claim that the bill was paid, while the doctor says only \$300 has been given him. The case is now in the courts.

Montgomery County

THE MEDICAL SOCIETY of the County of Montgomery listened to interesting papers on Oct. 28 at Amsterdam by Dr. Edward C. Reifenstein on "Management of Congestive Heart Failure," and by Dr. Joseph Wiseman on "Pneumonia."

New York County

DR. GEORGE WILSON MURDOCK, the oldest

living alumnus of the College of Physicians and Surgeons, Columbia University, died on Oct. 29. He was ninety-three years old and since 1900 had passed most of his time in England and on the Riviera. His home was formerly at Cold-Spring-on-Hudson, N. Y.

When fourteen he ran away to the Indian Wars. During the Civil War he served first as a hospital steward in the First Minnesota Cavalry, then with General Sibley in the campaign against the Sioux Indians and finally with a Michigan regiment in Sherman's army. He was appointed an army surgeon before he had completed his medical course, started at the University of Michigan.

DR. MEYER R. ROBINSON, gynecologist and obstetrician, who had served as attending surgeon at the Beth Israel Hospital many years, died at his home, 130 East End Avenue, on Nov. 2, after several weeks' illness. He was sixty-one.

Onondaga County

THE LAY FEATURES OF THE life-saving campaign to be conducted in Syracuse by the Maternal Welfare Committee of the Onondaga Medical Society, beginning in January and continuing through the winter, will include an educational crusade to induce more expectant mothers in straitened financial circumstances to take advantage of the free opportunities for prenatal care.

In this free prenatal service and maternal care three agencies co-operate. They are the College of Medicine of Syracuse University, the Nursing Bureau of the Department of Health and the Visiting Nurses Association.

There are now nine prenatal clinics in Syracuse, eight of which are staffed by nurses of the City Health Department and five in neighborhood centers.

The five neighborhood center clinics have medical staffs from the Obstetrical Department of the College of Medicine. The other clinics are served by physicians of the hospital staffs.

The records show that fifty-five per cent of the patients went to the clinics in the first five months of their expectant motherhood, which the Maternal Welfare Committee pronounces "an outstanding record."

All patients whose condition is found normal have their babies at home. Others are cared for in hospitals. Patients are seen at least every two weeks during the prenatal period and at least every week during the last six weeks.

Senior students of the Obstetrical Department of the Medical College care for

the mothers whose children are born at home, assisted by a visiting nurse. During 1935 there were 290 babies born in Syracuse under these circumstances

In Syracuse the deaths in each 1,000 births averaged nine in 1927. By 1935 this had been reduced to 37

"While these figures show marked improvement, they might be bettered," the Maternal Welfare Committee states, and that is the object of the coming winter campaign, which will include addresses by members of the Onondaga Medical Society to social, service, professional and other organizations of women in the city and throughout the county

Orange County

DR. EDWARD CARY RUSHMORE, medical director of the Tuxedo Hospital, which he helped establish in 1908, and president of the Orange County Medical Society, died at his home at Tuxedo Park Nov 2 at the age of seventy-four after an illness of several weeks

Dr Rushmore was president of the First District Branch of the New York State Medical Society

In the nineties Dr Rushmore, with several Tuxedo friends, became a pioneer in popularizing golf in the United States. He was one of the low handicap men of that day

He was captain in 1894 of the first team of American golfers to play abroad. Dr Rushmore won a driving contest, but the team was defeated by British players at St. Andrews

The doctor was also a tennis internationalist before the days of the Davis Cup

Orleans County

DR. FREEMONT W. SCOTT, eighty, dean of Orleans County physicians, and a former resident of Corfu, where he practiced a number of years ago, died Oct. 19 at the Medina Memorial Hospital after several years' illness

Dr Scott, who had been engaged in the practice of medicine for fifty years, was a past president of the Orleans County Medical Association, and an honorary member of the staff of Medina Memorial Hospital. At one time he maintained a stable of race horses for competition in county fair races

Oswego County

AT THE ANNUAL MEETING of the Medical Society of Oswego County held at the

Elks' home, Fulton, on Oct. 13, the following officers were elected for 1937

President, Dr O J Mowry, Minetto, vice-president, Dr K. W. Jarvis, Oswego, secretary, Dr J J Brennan, Oswego, treasurer, Dr J B Ringland, censor, Dr S D Keller, Fulton, chairman legislative committee, Dr E J Dillon, Phoenix, chairman public health and medical education committee, Dr John Hollis, Parish, chairman economics committee, Dr L De L Pulsifer, Mexico, chairman public relations committee, Dr C K. Elder, Oswego, delegate to state society, Dr R. F. Wolever, Fulton, alternate, Dr O J Mowry

A resolution was adopted endorsing the action taken by the Academy of Medicine of the city of Oswego in their attempt to obtain from the department of welfare remuneration for the care of hospitalized indigent patients

THE 115TH ANNIVERSARY of the Medical Society of Oswego County was celebrated by a dinner-meeting at the Pontiac Hotel in Oswego on Nov 12. The speaker was William D Johnson, M.D., F.A.C.S. of Batavia, past president of the Medical Society of the State of New York, and the subject, "Abdominal Catastrophes." Discussion by Grant C Madill, M.D., F.A.C.S., Ogdensburg, Albert G Swift, M.D., F.A.C.S., Syracuse, Professor of Surgery at the University of Syracuse, Hyzer W Jones, M.D., F.A.C.S., Utica

Queens County

FORMATION OF A SPEAKERS' BUREAU, consisting of prominent Queens physicians, is announced by the Queens County Cancer Committee from its headquarters in the Medical Society Building

Among the doctors serving on the speakers' committee are Dr Carl Boettiger, honorary chairman of the Queens Cancer Committee and chairman of the public health and public relations committee of the Queens County Medical Society, Dr William Hoffman, chief of the cancer clinic at St. John's Hospital, Long Island City, Dr Albert L Voltz, Dr Rudolph Boenke, Dr Ida Mintzer, Dr Francis Raley, Dr Joseph Thomas, Dr Joseph Wrana and Dr Irving W Ponemon

The Medical Society cooperated with the Cancer Committee in selecting the speakers

The speakers will give addresses, under the auspices of the Queens Cancer Committee before mothers clubs, teachers' groups and church and other organizations on the prevention and control of cancer

MEDICAL NEWS

[N Y State J M]

THE ANNUAL MEETING of the Medical Society of the County of Queens was held on November 24. Dr Charles Gordon Heyd, President of the American Medical Association was guest speaker. His paper was entitled "Organized Medicine—A Service to the Community." Election of officers took place at this meeting.

THE DENTAL PROFESSION of Queens County met with the Medical Society on November 30 at the Society's building. The purpose of this meeting is to encourage cooperation between the professions.

Schoharie County

THE ANNUAL MEETING OF THE Schoharie County Medical Society was held at the Cobleskill central high school on Oct 13. At the business session the following officers were reelected for the ensuing year: President, Dr Duncan L Best of Middleburg, vice-president, Dr Carolyn L Olenodorf of Cobleskill, secretary, Dr Herbert L Odell of Sharon Springs, treasurer, Dr LeRoy Becker of Cobleskill, censor, Dr W T Rivenburgh of Middleburg, and delegate, Dr David W Beard of Cobleskill. At the scientific session papers were read by Dr E K Cravener and Dr C W Woodall, both of Schenectady.

Westchester County

AN INTERESTING AND NOVEL EXPERIMENT in health education began to take form on October 5, at a dinner tendered by the Westchester Cancer Committee to teachers of biology and general science in Westchester schools. This dinner-meeting was called to consider the formation of a "Westchester Institute of Science" by which the Cancer Committee proposes to reach students in public school with sound information about the nature of cancer, its prevention and the importance of early diagnosis. It is hoped to break down the phobia now generally associated with the mention of cancer.

The dinner was attended by approximately 125 teachers, superintendents of schools and physicians. Dr C C Little, President of the American Society for the Control of Cancer, spoke on the biological nature of cancer and the application of this knowledge to an educational program. Dr George T Pack of Memorial Hospital, New York, also spoke, setting forth various fundamental facts about cancer which must be the basis of any sound educational treatment of the problem. Mr John G Farrow, a science teacher in Scarsdale High School,

presided and introduced the speakers. Dr H R Charlton, Chairman of the Westchester Cancer Committee, related the plans and hopes of his Committee for the development of this work.

UNDER THE AUSPICES OF THE Social Service Department of Grasslands Hospital, a series of talks and round table discussions will be given during December, January, and February, on the general subject, "The Social Significance of Disease."

This project has arisen out of many requests coming from staff workers attached to the various welfare departments and unofficial social agencies throughout the county for some organized information in regard to the consequence of various types of illness among relief clients and persons partially dependent upon private or public aid, in terms of the extent, duration and nature of the disability brought about by the various illnesses and the special attention which should be made available by welfare agencies for persons afflicted with these conditions.

It has been found that in many cases, the instructions and the treatment prescribed by the physician failed to be carried out by the welfare workers who are assisting the patients and on the other hand, the services of the attending physician sometimes fall short of their maximum value through lack of knowledge of the true social condition of his patient. Between the lay welfare worker and the practicing physician stands the medical social worker who is presumed to understand at least to some extent both the social and the medical approach to the case. These talks and round table discussions are designed to explain the physician to the social worker and vice-versa, in connection with each of the major categories of illnesses.

ORGANIZATION OF PHYSICIANS to promote medical service to the community and to provide for the welfare of a larger future population is necessary today, Dr Charles G Heyd, president of the American Medical Association, told seventy-five medical men attending the annual dinner of the Yonkers Academy of Medicine at the Yonkers Golf Club, on Oct 21.

"Doctors should not be concerned with an abundant life, but with a useful life," Dr Heyd told his fellow physicians. "When a doctor enters the medical profession, he undertakes an obligation to humanity which can have no selfish motive."

According to Dr Heyd, a doctor's organization must be based on standards of practice of medicine and not on a plan of regulating hours of work or fees.

Although the medical profession is faced with economic problems, its members must concentrate on service to the public and must hope for better times, he said. He cited the problem of doctors in New York City, where, he said, 50 per cent of the people go to clinics, thus lowering the private fees of physicians.

Dr Nathan B. Van Etten, speaker of the house of delegates of the American Medical Association, asserted that medicine will thrive only when individual doctors assume militant roles as citizens. He criticized compulsory public health systems.

He termed plans for socialization, in whole or in part, "abracadabra systems," holding that the doctor is bound to lose out if they are adopted.

Dr Van Etten predicted that voluntary health insurance would inevitably lead to a compulsory system and attacked compulsory workmen's compensation insurance as an instance of the "harm in such a plan."

He concluded:

"The doctor fails only because he fails to be a potent citizen."

THE FOLLOWING OFFICERS for the coming

year were elected on Nov. 17 by the Westchester County Medical Society:

President, Dr. Morley T. Smith of New Rochelle, Vice-President, Dr. Erich H. Restin of Mount Vernon, Second Vice-President, Dr. Ralph T. B. Todd of Tarrytown, Secretary, Dr. Merwin E. Marsland of Mamaroneck, Treasurer, Dr. Harry Klapper of White Plains, Censors (Two Years), Dr. Theodore West of Port Chester, Dr. Andrew A. Eggston of Mount Vernon, Dr. Francis Carr of New Rochelle (Censors continued in office by election last year—), Dr. Harrison Betts of Yonkers, Dr. E. F. Briggs of Mount Kisco, Delegates (Two Years), Dr. R. B. Hammond of White Plains, Dr. Arthur F. Heyl of New Rochelle, Dr. Walter W. Mott of White Plains (Delegates continued in office by election last year—), Dr. Merwin E. Marsland of Mamaroneck, Dr. Romeo Roberto of Yonkers, Alternate Delegates (Two Years), Dr. L. W. Haynes of Bedford Hills, Dr. R. A. Higgins of Port Chester, Dr. J. G. Morrissey of Yonkers (Alternate Delegates continued in office by election last year—), Dr. William R. Roane of Irvington, Dr. Isadore Zadek of Mount Vernon.

TERMINATION OF ONE THOUSAND ATTACKS OF MIGRAINE

Dr. Mary E. O'Sullivan, New York City (*A. M. A.*, Oct. 10, 1936), states that ergotamine tartrate administered to ninety-seven patients checked or aborted 1,042 attacks in eighty-nine of these persons. It was calculated that the individuals in this series were relieved from 39,000 hours of suffering. The earlier in the attack the medication is given, the better are the results. When used subcutaneously, the alkaloid has never failed to check again an attack in a person previously relieved if the drug was given in adequate dosage. Un- toward effects of the drug may be relieved

by simultaneous injection of 1/100 grain of atropine or calcium gluconate intravenously. She does not consider the drug a cure for migraine. She strongly advises against its dispensation without a consideration of the cause and prevention of the syndrome. Because of the constancy and character of the relief obtained from 1,042 headaches in eighty-nine sufferers of migraine after the administration of ergotamine tartrate, she recommends its use for the termination of these attacks and believes that the drug is a valuable addition to medical therapeutics.

SALESMANSHIP IN MEDICINE

Certainly there is an important place in the practice of medicine for the practical application of psychology or salesmanship, remarks the *Journal-Lancet*, of Minneapolis. The real value and aid of a clean, light, airy, cheerful office, a pleasant attendant, and a physician who is a good salesman cannot be over-estimated.

All too many doctors neglect personal appearance, facial expression, pleasant voice, enthusiasm, and personal interest in

the patient, which are the fundamentals taught every salesman. The direct relationship between the doctor and patient has been allowed to assume a scientific basis rather than to consider the patient as an ordinary human being, with the usual sentiments and emotional reactions. The sentimental and personal relationship between doctor and patient should be the most pleasant and most sought-after reward of a busy practice.

Medicolegal

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Limitation of Actions Against A Physician

One of the legal questions that repeatedly arises in connection with actions brought by patients against physicians is whether the action has been instituted within the statutory period of limitation. The general rule in New York State is that such actions must be commenced within two years after the cause of action accrues, and various other jurisdictions have a similar statutory period. Frequently a malpractice action is brought where the plaintiff either seeks by some device to extend the time that the cause of action "accrued," or to institute the action in such a form that it will be governed by rules of law applicable to types of actions other than those based upon alleged malpractice. An example of such an attempt to evade or avoid the operation of a two year statute of limitations recently was before the Courts of one of the New England States*.

The case was one in which the plaintiff's grievance against two physicians centered around an operation which they had performed upon her five and a half years prior to the date of the first papers served in the action. The charge was that the defendants B and C were negligent in the performance of the operation upon the plaintiff, A, and that it was unnecessary, unwise, and impractical. The complaint included the claim that the defendants had until thirteen months prior to the commencement of the action fraudulently concealed from the knowledge of A the fact that she had a cause of action. The answers served by the defendant physicians were the usual form of general denials, and the special defense that the actions were barred by the statute of limitations.

Upon the trial, the only evidence before the Court was that introduced by the plaintiff and her witnesses. It appeared that for some years prior to her contact with defendants, plaintiff had suffered from a condition diagnosed as a sacroiliac strain which followed a knee injury. She had consulted various doctors and had received certain treatment with apparently no improvement. When she consulted the defendants, according to A, she was placed under observation for a few days and an operation was advised. She claimed to have been told by

both B and C that if the operation was performed she would leave the hospital in six weeks, and be well in two months, and on those assurances she consented to undergo the proposed operation.

The operation was performed, and its purpose was described as being to produce a fixation of the right sacroiliac joint, by the insertion between the sacrum and ilium of a piece of bone from the ilium. The result was to be accomplished by the union of such piece of bone with the ilium and sacrum. The defendants attended the patient almost daily after the operation until she was discharged from the hospital about nine weeks later. Both doctors attended her on a certain occasion some months later during the same year.

The plaintiff's testimony was to the effect that from that year of the operation until the year before suit was started, her contact with the defendant B consisted of correspondence concerning her condition, and occasional personal consultation, and that her contact with C consisted of one consultation the year before she commenced her action. She claimed that on that occasion C had told her that the reason the operation was not a success was that they had used too small a piece of bone, and that if another operation was undertaken a larger piece of bone could be used to cause her to be well in a short time. According to A, C also told her that unless the proposed second operation was undergone she would always remain a cripple useless to herself and others. She further claimed that at the approximate time of the said conversation with C, B had given her the same sort of a story, and had advised a further operation at the hands of C. A also introduced expert testimony that the original operation had been improperly performed.

Upon such evidence, the Court directed a verdict in favor of each of the defendants ruling that the action against each of them was barred by the two year statute of limitations, and that the claim of fraud had not been sustained to justify her action against the doctors more than five years after the operation. The plaintiff appealed from the determination of the Trial Court, and the highest Court in the State affirmed the ruling. In so deciding the Appellate Court said in its opinion:

* Maloney vs Brachett 176 N E 604

The prediction by the defendants as to her recovery made before the operation was performed had no tendency to prove that the doctors did not in good faith consider the operation advisable. If it be a fact that she first discovered in July or August 1925 that too small a piece of bone had been used in the operation, this would not prove that the operation itself was unnecessary, unwise, and impractical. The testimony of an expert witness in reply to a long hypothetical question, asked by the plaintiff, that in his opinion the operation in 1921 was inadvisable, might justify a finding to that effect, but would have no tendency to prove that the defendants did not believe that the operation was advisable when made. The concealment to which the statute refers (permitting an action to be brought after the discovery of a cause of action fraudulently concealed) is of the cause of action and not of the injurious consequences following from it. Failure to state in detail the nature of the operation, concealment of facts concerning the plaintiff's condition after the operation, or concealment of the fact that too small a piece of bone had been used in the operation, or assurances then made as to her recovery could have no tendency to prove a fraudulent concealment of a cause of action for negligence based on performing an operation where none was needed. The plaintiff knew that she had been suffering from a sacroiliac strain for more than two years, that the operation was to be performed upon her right sacroiliac joint, and that before the operation a cast had been made upon her body to be used upon her after the operation had been completed. She testified that in October 1921, she asked the defendant B, if he would consider taking out the bone that had been put in, and again in the fall of 1922, she asked him to consider operating on her and taking out that bone. She had been treated by doctors in her home city of H after the operation, and was in a hospital in H in June 1924 for ten days. At this hospital, X-rays were taken and she was placed in a plaster cast. At some time prior to 1924, she had been examined by a doctor in Boston. She testified, in substance, that at all times since the operation her condition had been worse than before.

A cause of action cannot be said to be concealed from one who has a personal knowledge of the facts which create it." The rule that fraud cannot be presumed applies to a charge of fraudulent concealment of a cause of action. Ordinarily mere silence concerning the cause of action or failure to inform the plaintiff of the facts upon which her cause of action rests is not a fraudulent concealment within the meaning of the statute. The fraud referred to in the statute must be actually accomplished by positive acts done with the intention to deceive. If a defendant is a deliberate wrongdoer and is also charged with the duty to disclose his wrong to the plaintiff, the rule that a plaintiff is bound by knowledge of facts which might have been learned upon inquiry may not apply. But the failure of a doctor to disclose a cause of action to a patient could not be found to be a

breach of his professional duty without evidence that he knew or believed that a cause of action existed, and we discover no evidence that either defendant knew or believed that he had performed or assisted in the performance of an unnecessary operation, and none of such a violation of professional duty or concealment of facts as could establish a fraudulent concealment within the meaning of the statute. We are not concerned with the conduct of the defendants except in so far as it is material to this issue. Upon all the evidence considered in the light most favorable to the plaintiff, the order directing a verdict for the defendant in each case was right.

Death Following Removal of Stone from Ureter

A man thirty-nine years of age was referred to a physician specializing in surgery with respect to complaints of pain over the right kidney. He gave a history of having had attacks of renal colic and hematuria for several years. He was placed in a hospital under observation for x-ray and cystoscopic examination which revealed a stone in the right ureter. An operation was performed upon the patient for the removal of the stone under a general anesthesia, which operation was apparently successful. His convalescence was uneventful for five days when the patient complained of difficulty in opening his mouth and some stiffening of the muscles of his neck. Consultation was arranged between the surgeon and a neurologist with respect to his condition and a diagnosis was made that the patient was suffering from tetanus. Tetanus antitoxin was administered. Spinal fluid was found to be under pressure and a hemolytic streptococcus was revealed upon culture. Although all possible steps were taken to care for the patient he died within two days.

A postmortem examination indicated that the patient had suffered from an acute meningitis caused by staphylococcus aureus.

An administratrix of the deceased instituted an action against the surgeon in which the charge was made that negligence in the operation had produced the conditions which eventually caused the patient's death, that the symptoms after the operation had been incorrectly diagnosed and treated.

The plaintiff's attorney repeatedly attempted to induce a settlement of the case but no settlement was made. When the case was reached for trial no attorney appeared on behalf of the plaintiff to try the case and the Court on motion of defendant's counsel dismissed the action.

Across the Desk

A Mysterious Case Solved

A STORY IS GOING THE ROUNDS of the Medical press about a man who visited a Colorado physician and complained of pain and soreness just to the left of the sternum over the precordium. It was growing worse day by day. The doctor gave him a thorough physical and laboratory examination, explored his personal and family history—all in vain. If the doctor had been well up in psychiatry, perhaps he would have found out all about his dreams and night thoughts, too, but this was apparently neglected. The man was "physically strong and capable, ruddy, well-nourished," evidently prompt at meals, but, it appeared, "able to work only when under a boss's nose." He was "resting quietly in the most comfortable chair in the office."

All this seemed to point in one direction, and when further questions revealed that the patient was a WPA "worker," the medical man had the clue.

The painful area was at about the spot where a shovel would reach! Diagnosis "Osteochondralgia secondary to constant leaning on a shovel." This case assumes importance if our army of shovel-leaners is to continue in the coming years. It recalls the story of the WPA worker who complained bitterly to the boss that his feet were tired because he had no shovel to lean on like the rest. The moral drawn by a Western medical editor is that "it is your money and mine that has nurtured a generation of chisellers, and it will be our money and our sons' money that will carry them on."

Left-wingers are on the Wing

The question of the hour, with the medical profession, is whether the doctor will have to keep on supporting the "chisellers" by his taxes, and also give them medical attention at the pitifully low fees dictated by the relief authorities. This is a system that may glide easily into socialized medicine if the profession is not on its guard, and the election has encouraged all the left-wingers to urge their socialistic schemes more strongly than ever before. Washington dispatches say that the leftist labor forces led by Lewis and Major Berry

are out with a program of social legislation which they hope to rush through Congress and into the statute books under the impetus of the tidal political wave of November third. One plank is "Further liberalization of the Social Security Act to provide socialized medical care for low-income groups." And they evidently do not intend to have their program knocked on the head by the aged if wise jurists of the Supreme Court, either, for their concluding plank is the "inclusion of a provision in all new legislation forbidding its invalidation by the United States Supreme Court."

This amusing, not to say childish, idea recalls the equally clever device of certain European lawmakers some years ago who tacked a clause on their pet measures saying that "this law shall never be repealed." A later parliament, of course, merely had first to repeal the non-repeal clause, and then repeal the rest of the act. In the same way the sober justices, if they can keep their faces sober, may first declare the no-invalidation clauses invalid and then rip the laws, if unconstitutional, into as small pieces as they may like.

A Ride on the Merry-Go-Round

Another report from Washington, in a syndicated column called "Daily Washington Merry-Go-Round," pretends to say explicitly just what the President intends to do on every big question now before the country. Under the heading "Socialized Medicine," the writers of the column declare "This was knocked out of the Social Security Act by pressure from organized physicians, but it is now on the President's list of 'things to be done'." The net impression made by this downright declaration of what the President has in his mind on every subject is that it sounds a bit too cocksure to be authoritative. Perhaps we shall do best to take the authors at their own valuation and consider that they are just taking us for a ride on their merry-go-round, a delightful device that is loads of fun, but always brings us right back to the place where we started.

Let the President Speak for Himself

At any rate, we have to put over against this the statement made by the President himself a few weeks ago at the dedication of the Jersey City Medical Center. His expression on that occasion may well be preserved and kept on record for reference at any future time when and if the socialization of medicine seems to threaten us. As quoted in the *Journal of the AMA* on October 10, page 1226, he said:

The medical profession can rest assured that the Federal Administration contemplates no action detrimental to their interests. The action taken in the field of health as shown by the provisions of the splendid Social Security Act recently enacted is clear.

There are four provisions in the Social Security Act which deal with health, and these provisions received the support of outstanding doctors during the hearings before the Congress. The American Medical Association, the American Public Health Association and the State and Territorial Health Officers Conference came out in full support of the public health provisions.

This in itself assures that the health plans will be carried out in a manner compatible with our traditional social and political institutions. Let me make that point very clear.

The opinion is expressed in well-informed quarters that the President is not likely to advocate any policy opposed by organized medicine in this country.

An Appalling Leftist Proposal

At the same time we get a vivid glimpse of what the leftists can advocate by glancing across the water at what is happening in France, where a government of the left, or a "popular front," is in power. One of the left members has introduced a bill in the Chamber of Deputies providing that "no one can practice, even without pay, after the age of sixty-five years, as a lawyer, physician, veterinary, dentist, druggist, architect, surveyor, engineer, accountant, or as an executive in any commercial pursuit." No pension would be provided for those thus robbed of livelihood. A medical journalist is quoted in the *Presse Medicale* as saying that under this law he would be forced to retire in three months and by 1939 would either be in the soup line or be obliged to earn his living by singing in the streets, as many other unemployed are doing.

The idea of the bill is that it would give jobs to the younger men, but it is worth noting that among the strongest opponents of the bill is the Medical Students Association of France, and other young people are equally opposed to it, purely on the grounds of justice. Such a measure may seem like a figment of the brain of a dreamer, remarks the *Concours Médical*, yet there it is, actually before Parliament. There is little chance that it will pass, or even come to a vote, we are assured, but it is worth noting as an example of what our visionaries are capable of when they "get going."

A New Deal Health Miracle

So much has been said in criticism of various governmental agencies that it is a pleasure to report a striking example of great benefit to public health, credited to the much-berated New Deal. We find it set forth in fact and figures in the *Journal* of the South Carolina Medical Association, which is on the spot, and told by Dr. C. J. Milling, of Columbia, who supports his point with a wealth of statistics.

Perhaps not many are aware of the precipitous drop in pellagra cases in South Carolina and neighboring states since the start of the depression. The sharp fall in pellagra may seem all the more surprising when we recall that it is associated with poverty and malnutrition, and hence might perhaps be expected to increase, instead of decrease, with hard times. The pellagrins, says Dr. Milling, "is the victim of undernourishment, particularly in regard to protein and vitamin deficiency." Well, in 1928, the pellagrins constituted 28.5 per cent of all admissions to the South Carolina State Hospital, with 287 sufferers and 124 deaths. In 1929 there were 295 victims admitted, and 121 deaths. Then the depression struck, the New Deal came in, and in a few years a vastly different picture appeared. In 1935 the number of pellagrins admitted to the state hospital had dropped from 295 to 54, and the number of deaths from 121 to 20. Turning to the figures for the entire state, in 1929 there were 7849 cases, with 909 deaths, and in 1935 there were only 1991 cases with 310 deaths. A disease of poverty had dwindled incredibly as the people became poorer!

The Answer to the Riddle

What is the explanation? True, we may give a certain amount of credit to general educational enlightenment, to public health propaganda, and, as our informant notes, to the widespread adoption of brewer's yeast both as a preventive and a therapeutic measure. We may note, too, that the factory hands thrown out of work went back to the land and raised fresh foodstuffs, the very thing to combat pellagra, but all these together, thinks Dr Milling, would not account for the drop. The only other big factor in sight was the New Deal. "Is it not, therefore, reasonable to conclude that, in the free distribution of foodstuff, the creation of new jobs under the various relief agencies, the CCC camps and the di-

rect relief afforded by the Administration, we have the answer? I think the figures show too close a relation to the New Deal for us to disregard them. It is true that 1928 and 1929, the worst pellagra years, were the period when two cars were supposed to repose in every garage and a chicken in every pot, but they were also the years when money crops were raised to the exclusion of food crops, and when earnings went not into intelligently selected food, but into vacuum cleaners and radio sets."

Here is an intriguing chapter in the medical history of the Great Depression. No doubt others are still waiting to be written. The big fact is that while everything else slumped, the people's health did not slump. And that fact will stand forever as a shining monument to American medicine.

"SEVEN STEPS TO THE UNDERTAKER"

This term is used to designate seven fallacies about cancer entertained by some physicians, as found by Dr Frank L. Rector, Field Representative of the American Society for the Control of Cancer, in six years of travel and discussion in the Middle West. He lists the seven fallacies or "steps" as follows:

Step 1 "Efforts to enlighten the public about cancer only stimulate cancerphobia and increase morbid fears about the disease."

Step 2 "Cancer education drives the public to quacks."

Step 3 "The profession has no cure or even hope to offer the cancer patient."

Step 4 "Treatment often increases the patient's suffering."

Step 5 "By telling the patient the truth, his condition is often aggravated."

Step 6 "The patient will not cooperate in treatment."

Step 7 "A watchful waiting attitude on the part of the physician is often the best method to pursue."

NOT LIKE THE USUAL "WHITE ELEPHANT"

A young woman, Miss Joyce Victoria Deutsch, received the Mitchell Prize at the graduation exercises of the Long Island College of Medicine, given to "that member of the graduating class who in the judgment of the faculty is best qualified in all the departments of medicine." "Tall, pretty,

brown-haired, blue-eyed, slender despite her boasted 130 pounds," the twenty-two year-old medical maiden will enroll as an interne in pediatrics in the Brooklyn Jewish Hospital. In the rather breezy newspaper accounts she is said to lay all her success to a tiny silver elephant, a talisman.

A RECEPTION ROOM HINT

A clean, well-lighted, pleasantly furnished waiting room with small brightly painted chairs for children, comfortable chairs for the grown-ups, and up-to-date, untorn maga-

zines immediately put the patient into a good frame of mind. A neat, attractive receptionist always adds to this good impression.

A questionnaire reveals that the average British family pays the doctor £4 15s a

year. This will be news to the doctor.

REVIEWS

Johannes De Mirfeld of St Bartholomew's, Smithfield. His Life and Works By Sir Percival Horton-Smith Hartley, M D & Harold Richard Aldridge, M A. Octavo of 191 pages New York, The Macmillan Company, 1936 Cloth, \$4 50

This is a beautiful book of 191 pages, including appendices and index. It treats of the first medical writings, known to be associated with any English hospital, and is an exhaustive examination of the activities of one Johannes de Mirfeld, who lived in the days of Richard II and wrote within the Priory of St. Bartholomew in Smithfield.

The work is divided into three parts, as follows

I Introduction, 1 The life of Johannes de Mirfeld, 2 Johannes de Mirfeld as a Medical Writer

II The Breviarium Bartholomei, described by the authors as, in form, a "great medical compilation—upon which rests his claim to be a physician" To it is added much superstitious and magical lore—incantations and charms. There are eight chapters in Latin, with an English translation on the opposite page and two photostats of the original manuscript.

III The Florarium Bartholomei, a theological treatise of 175 chapters, one of which is entitled "Physicians and Their Medi-

cines." This latter chapter is reproduced in the book, in Latin and English, with two photostats, one being Mirfield's will. The manuscript is beautifully written in fourteenth century Latin and is redolent of medieval atmosphere. It is a fine piece of "laboratory" work, well worth a place on the shelf of one interested in medical history.

J M VAN COTT

Sensation Its Mechanisms and Disturbances an Investigation of the Most Recent Advances Association for Research in Nervous and Mental Disease, volume XV of a Series of Research Publications Octavo of 541 pages, illustrated Baltimore, The Williams & Wilkins Company, 1935 Cloth, \$7.50

This volume is the fifteenth contribution of The Association for Research in Nervous and Mental Disease.

It is made up of four sections and chapter subheadings, the work of 33 investigators, each dealing with a distinct phase of the problem. Section I deals with Peripheral Nerves and Sensory Nerve Endings, Section II with Visceral Sensations, III with Sensory tracts and Mechanisms in the cord and Brain, IV with Clinical Cases.

It is enriched by 153 illustrations and 31 tables. Unusually lengthy lists of references are appended to each Chapter.

This book adds to the growing reputation of these annual publications, fast becoming an indispensable part of a neurologist's library. It is virtually impossible in a brief review to cover such a volume adequately. The complete historical surveys of each phase of the problem and the additional new data make it a worth while acquisition.

H R MERWARTH

A Practical Manual of Diseases of the Chest. By Maurice Davidson, M.D. Octavo of 528 pages, illustrated New York, Oxford University Press, 1935 Cloth, \$14.00

Dr Maurice Davidson presents to the medical profession a valuable book on the Diseases of the Chest. Intended primarily for the specialist in this field, the general practitioner, too, will be well repaid for its study. Changes that have taken place in recent years in descriptions of these diseases, in studies of their pathology, diagnostic refinements afforded by laboratories, bacteriological and X-ray, the interpretation of X-ray plates, increased knowledge of treatment and definite indications therefor are well given. The indications for thoracic surgery and the results to be expected therefrom are clearly drawn. The reader is quickly shown that thoracic surgery means more than thoraco plastes for tuberculous patients. The treatment of empyemata and

all intrathoracic suppurative processes are approached from conservative, safe and valuable viewpoints. Medical treatment is not minimized. One must praise the illustrations in this book. There are 199 of them. They are well made, very informative and appropriate to the particular subject shown. The X-ray illustrations of the normal chest should be of much assistance to the general practitioner.

There is no hesitation in commending this book and appreciating its usefulness.

THOMAS A MCGOLDRICK

Recent Advances in Dermatology By W Noel Goldsmith, M.D. Octavo of 522 pages, illustrated Philadelphia, P Blakiston's Son & Co., Inc., 1936 Cloth, \$5.00

This book of 500 pages is one of a series of "Recent Advances" in various branches of medicine. Unlike our Year Book, however, it takes in the accumulated advances in dermatology over a period of approximately 20 years, and its style is not that of a review of published paper after published paper, but, rather, all the research work and clinical experience of many writers has been welded into one whole with the experience of the author.

In the early chapters one finds rather detailed and pertinent descriptions of the minute vessels of the skin, and their response to stimuli of various types eg stroking, ultra-violet light, temperature changes, etc. One is shown how the nerve supply of the blood vessels alters their response, and the effect of injections of histamine, etc.

Under "Pigment" we find the melano-blasts, and various pigmented nevi, as well as a discussion of leucoderma and sundry forms of hyperpigmentation. The endocrine, nervous, and mental influences on skin diseases are presented as well as the relationship to the reticulo-endothelial system.

Disorders of metabolism and allergy come next, with, we believe, unbiased expression of opinion as to their definite position in the role of cutaneous disturbers.

A classification, and discussion, of cutaneous tuberculosis, and cancer, are to be found, and the effects of the various forms of radiant energy.

One picks this book up with an idea of skimming through it, and finds the necessity of reading thoroughly, attentively. As the author remarks in his foreword "If someone is to profit from reading it, he will stand most chance, I think, by ploughing bravely through the chapters in their proper order (and then, perhaps, doing it again)."

The reviewer has had his first reading and shall look forward to the second one.

E ALMOUR GAUVAIN

A Synopsis of Physiology By A Rendle Short, M D and C I Ham, M B Second edition edited by C L G Pratt, M D Duodecimo of 312 pages, illustrated Baltimore, William Wood & Company, 1936 Cloth, \$3 50

The text of this little volume is made up in general of systematized statement of matter-of-fact findings and widely accepted explanations of animal—predominantly human—physiologic phenomena and processes, being intended as a handy, reliable mnemonic aid for students of the subject in general, for practising physicians and surgeons in particular and for any others who, though possessed of the required basal knowledge, have failed to keep abreast of recent advancement in the subject. As such it is frankly recommended and its authors congratulated

JOHN C CARDWELL

A Textbook of Surgery by American Authors Edited by Frederick Christopher, M D Octavo of 1608 pages, illustrated Philadelphia, W B Saunders Company, 1936 Cloth, \$10 00

This text comprises 1600 pages of a compendium by American authors on the major problems of surgery. The medical profession has had many similar texts presented in the past. The majority of them have been too cumbersome and voluminous to lend themselves to easy usage. This volume has overcome these objections. The author has restricted his contributors and the entire subject matter is included in a single volume. While such a compendium will require frequent editions in order that the subject matter may be constantly up-to-date, nevertheless, the present volume is one of the most splendid and modern descriptions of surgical problems for the student and practitioner.

184 contributors have apparently one object in mind—to present their subject as a teacher of their specialty. We believe that this has added greatly to the value of their efforts. Although etiology, symptoms and diagnosis have been stressed throughout, operative procedures have not been neglected. Happily, however, these operative procedures have been described in such a manner that the reader is impressed by what should be done in treatment rather than how it should be done. The technical details have not been entered into except in an outline manner.

The illustrations are adequately abundant and serve their purpose admirably.

In general, this book should be welcomed by the profession as one of the outstanding surgical texts of a generation.

ROBERT F BARBER

Clinical Heart Disease. By Samuel A Levine, M D Octavo of 445 pages, illustrated Philadelphia, W B Saunders Company, 1936 Cloth, \$5 50

In the preface the author states that the book is not an attempt to cover in detail the entire field of cardiovascular disease, but to present in simple form the important aspects of diagnosis, prognosis and treatment of heart disease. He has succeeded admirably in this purpose. The book is full of valuable information and contains much that is not included in the ordinary text book. It represents mainly the author's own experience in this field. It is extremely practical and stresses the great value of clinical observation. Many stimulating thoughts are presented regarding phases of the subject which are at present obscure. The book can be highly recommended to the general practitioner, for whom it is written, but should also be greatly enjoyed by those primarily interested in cardiovascular disease. It is well printed and the illustrations are excellent.

J HAMILTON CRAWFORD

Emergency Surgery By Hamilton Bailey, F.R.C.S. Second edition Octavo of 842 pages, illustrated Baltimore, William Wood and Company, 1936 Cloth, \$14 00

The second edition of this work is now in one volume of 842 pages. There are 812 illustrations, many in color, and most of them necessary and descriptive. The author explains in his preface to the second edition, "When to operate, when not to operate, and how to operate under emergency conditions is the theme." While it may be contended that he has allowed himself some latitude in the interpretation of what constitutes a real surgical emergency, he does handle the undoubted emergency cases with discrimination and judgment. The subjects are divided into 52 chapters, on a grossly anatomical basis, with a short and pertinent bibliography at the end of important chapters.

In some respects, a similar book by Felix Lejars, "Urgent Surgery," has a more logical and didactic approach in the discussion of the indications for the kind and character of the surgery to be done—the "What shall I do next" method of meeting the emergency. But Dr Bailey has taken his cases from actual reports and personal experiences, and offers a clear and definite procedure for the condition under consideration. What makes the book so worthwhile is the ease with which it can be read and the feeling of satisfaction at the amount of information so readily and pleasantly acquired.

J RAPHAEL

Allergy of the Nose and Paranasal Sinuses
A Monograph on the Subject of Allergy as Related to Otolaryngology By French K. Hansel, M D Quarto of 820 pages, illustrated St. Louis, The C V Mosby Company, 1936 Cloth, \$10 00

This is a most comprehensive monograph. It covers the subject thoroughly and is replete with references for the student. The author not only treats of all the features of allergy as related to the field of otolaryngology and reviews the subject completely but he also points out the frequent association of the nasal with other manifestations, particularly asthma, gastrointestinal allergy, allergic skin diseases, and allergic headache. To bring home the principles of diagnosis and treatment, liberal use is made of case reports. Where there is interlinking with other specialties, such as pediatrics, ophthalmology, and general allergy, the various phases are clearly discussed.

Because of the importance that allergy is assuming in modern medicine, this book should be of value to every general practitioner and specialist. THOMAS B WOOD

A Manual of the Common Contagious Diseases By Philip M Stimson, M D Second edition Duodecimo of 437 pages, illustrated Philadelphia, Lea & Febiger, 1936 Cloth, \$4 00

In this second edition, Dr Stimson has given us a book excellently practical. The text runs smoothly neither interrupted by quotations from supernumerary authorities nor drawn to the tiresome length of all probable complications. In fact the book is pleasant to read.

While not exhaustive enough to satisfy the advanced students, the nurse, student of public health, the medical student and the busy practitioner will welcome its adequacy, brevity and clarity.

The chapters on medical aseptic technic, the management of contagious diseases in the school and the home as well as the schematic summary of useful information at the end, increase the book's value. The glossary will be a boon to the nurse.

K G JENNING

The Balanced Diet. By Logan Clendening, M D Duodecimo of 207 pages, illustrated New York, D Appleton-Century Company, 1936 Cloth, \$1 50

A large number of popular books on diet have been published within the last few years, some good and others not so good. This little book by Dr Clendening is undoubtedly the best thing on the subject for the layman that the reviewer has had an opportunity to read. It is most entertaining and enlightening. The author's imitable style and accurate presentation of accepted concepts of metabolism and nutrition

makes this book an ideal one for the physician to recommend to his patients. The author discusses the physiology of metabolism and its practical application to the study of nutrition. The second part of the book is devoted to the problems of infant feeding and diet in disease. There is an excellent chapter on food fads in which Dr Clendening exposes the various misconceptions and pseudo-scientific basis for such fads as naturopathy, fasting, Hay diets and vegetarianism. WILLIAM S COLLENS

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Richard M Hewitt, M D, Lloyd G Potter and A B Nevling, M D Volume 27, 1935 Octavo of 1353 pages, illustrated Philadelphia, W B Saunders Company, 1936, Cloth, \$12 00

In this year's volume of assembled papers there is maintained the usual high standard of previous volumes.

The material is well arranged, and the papers cover fairly well the field of clinical surgery with an occasional article devoted to laboratory investigations in related fields. More than half of the articles are by abridgment which does not impair their value for quick reference. Over 450 articles, appearing by title only, are so listed as to furnish a very useful guide to the general medical and surgical literature.

EDWARD P DUNN

My Life and Work. The Search for a Missing Glove By Dr Adolf Lorenz. Octavo of 362 pages, illustrated New York, Charles Scribner's Sons, 1936 Cloth, \$3 50

This book of 362 pages is written in popular style by a genius who has also a very human personality. His early life is interestingly recorded. He made rapid progress in the field of surgery, and soon became a Court figure. His description of the Viennese Court life and the rigid ceremony of the old Emperor, Franz Joseph, is true to form and pleasing. So also is his experience in America. The book is replete with humorous sketches and direct criticisms of men and things. But back of it all is the record of a strong character, a direct shooter, abounding in energy and determination. In all of the years of arduous labor in a difficult field, Dr Lorenz finds time for relaxation, music and art, and the pleasures of good society. One cannot read the book without being stimulated by its record of over half a century of vigorous work in a field of surgery, very much the making of the author himself. Nor can one escape the realization, that, aside from a large and lucrative practice, Dr Lorenz did an enormous amount of charity work on patients from all parts of the globe.

J M VAN COTT

Skippy and David Explore THE *New* BOOK OF KNOWLEDGE

"WE ARE a second generation Book of Knowledge family," writes Mrs E M Rutter, mother of the boys pictured above. 'I was brought up on, and adored, the first edition that came out more than twenty five years ago. As soon as I saw your wonderful new edition, I felt that it was absolutely necessary for the boys to have it for their school work and for home reading. I notice how wonderfully you have kept up with all the changes. I don't want to praise my own children, but it certainly has put them along in school and it is the best possible background a child can be given."

Already in the Homes of
3,500,000 Children

The Book of Knowledge introduces the boy and girl to the world of knowledge in the happiest and most interesting way. By means of his own natural curiosity the child is led into the wide fields of Nature Study, Science, History, Biography, Literature, etc. 15,000 striking pictures provide visual edu-

cation in its simplest and finest form. The Book of Knowledge, already in the homes of 3,500,000 children, stores the mind with useful information and exerts profound influence on character.

The Trained Mind Wins

When your child starts asking "Why is the sky blue?" "Why are raindrops round?" and the hundred other daily questions that bespeak an eager, inquiring mind, that is the moment, THE MOMENT OF INTEREST, when The Book of Knowledge should be at hand, to supply the right answers. The child whose questions are answered becomes a well-informed man or woman, with a clear, trained mind, prepared for success. In school days and in the fierce competition of grown up years, the trained mind carries off the biggest prizes. The Beautiful Free Booklet will delight your boy or girl. Send for it today.

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines its step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

PRIVATE
SANITARIUM

*recognized for 50
years by the medical
profession*

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases

Environment and administration are such as affords the most beneficial atmosphere. Contact with others is controlled through caring for the patients in suites (practically all with private baths). A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanitariums.

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal. The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere.

Select Schools

IN EDUCATIONAL AND CULTURAL ADVANTAGES

in life. Here is a school family, all working together, even in their recreation and social hours, to rise to higher and higher levels

Students are admitted only after personal interviews, so that undesirable elements are kept out, and the student's associations are of a high type. Large classes, with mass-teaching, is unknown. Classes of ten or fifteen students each are the rule, and each pupil has individual attention. The faculty knows intimately how every one is progressing, and frequent reports keep the parents fully informed. In many schools a character analysis is made periodically by the teachers, hall masters, athletic instructors, and other advisers, covering the student's industry, initiative, integrity, personality, leadership, versatility, and many other qualities. This gives a check on each pupil by several teachers acting independently. Together, they make a composite record useful to pupil and parents in helping to develop character on the right lines. It is friendly and helpful cooperation of this sort that may mean the difference between success and failure in the after years.

Again, the school staff aim to co-operate with the parents, just as the patient co-operates with the Doctor in the restoration of health.

Education means the symmetrical development of soul, mind, and body. Neglect of any one of these makes an unfinished man. The most dangerous men in society are educated men whose moral character is deformed, either by nature, which is very rare, or by neglect of early training.

Another aim is to give the mind power rather than attempt merely to store it with information. The power to know is more important than knowing. Recitations are but daily affairs. The ability to think is for a lifetime and its influence upon others is for eternity.

THE EXPERIENTIAL GROUPS

For girls between the ages of eighteen and twenty-two who wish to use New York City as a laboratory for the study of problems such as are offered by industry, government, international relations, social welfare, drama, and the fine arts. EDUCATION

It is often a mistake to think that the child who seems to need special care is better off at home than entrusted to a special school. A mother's care may be the most tender and loving in the world but at the same time it may not be the most intelligent, it may be very far, in fact, from what is best. In the home the child who is a bit backward, mentally or physically, is apt to be coddled or "babied" in precisely the way to confirm all its habits of weakness and make its condition permanent. Or, on the other hand, harsh methods are used with equally deplorable effects.

In the special schools for such children however, instructors prepared by years of training know how to lead the little minds and bodies from paths of weakness to paths of strength. Some of the results obtained by such training are remarkable. Often the apparently backward child only needs the right training and treatment to develop into a healthy, happy, normal boy or girl. Special schools of this kind are always glad to give any information desired to physicians seeking the best school for children of their patients.

It is not enough in these days of keen competition to train the mind alone. Boys and girls are being judged nowadays by their personality and character just as much as by their mental ability. When choosing a school, this point must have full consideration. Does the school develop character? The public school gives a splendid intellectual training. The private school goes far beyond that. Its teaching staff is the product of many years of building. The faculty members are chosen with scrupulous care, and changes are infrequent. Here are men and women who know how to prepare the boy and girl for everything that is best.

Travel and Resorts

A Sunday in Leysin—the Front Lines of Tuberculosis Warfare

As Lausanne is on the shore of the lake of Geneva, we cannot expect the sky to be always clear in Winter, but, if we wish the sunshine, we have only to take the electric train and in less than two hours we are sure to have our desire gratified

We not only wished to seek sunshine, but to visit Leysin, the celebrated climatic station where the marvelous work of Dr Rollier is being carried on. We took the early Geneva-Simplon train. Hundreds of people, young and middle-aged, who love the fresh mountain air and the vigor which it brings, boarded the train, most of them with skis. Gay colors added interest to the lively scene. There was no rushing, no pushing—order was observed everywhere.

As we approached Montreux about eight o'clock, one after another the mountain tips of Gramont, Cornettes de Bise and the seven peaks of the Dent du Midi were lighted up and by the time we reached Teritet, deep shadows were cast down the deep mountain sides and the mist became rose-tinted. The windows in a little hamlet hung on the mountain side glistened like electric lights.

*Special
to
THE JOURNAL
by
Mary
Vanderbilt*

Above A patient enjoys the beauty, fresh air and restfulness of Leysin, Switzerland. And the famous sun school of Dr. Rollier's near Leysin.

Below Patients occupy their time profitably at the International Factory Clinic—and at Dr. Rollier's find pleasant diversions.

At Aigle we changed for the electric cob railway which connects the plain and the mountain-tops, and winding through the woods and crossing the deep ravine, we soon reached Leysin. This village, backed against the south-eastern slope of the mountains, is protected against the north wind, and possesses all the advantages of a high altitude of 4150 feet a/s, pure, dry air and lengthy winter sunshine. Before the value of a dry climate and a high altitude had been scientifically ascertained, and when Leysin was connected with the plain by a single footpath, patients were sent here and housed by the peasants. Owing to the wonderful benefits derived by these patients under treatment for tuberculosis, Dr. Rollier, in 1903, opened his first nursing home for the systematic treatment of surgical tuberculosis by means of solar rays. The results which were obtained caused such a large number of patients to seek aid that today there are thirty-two sanatoria capable of caring for three thousand patients. These sanatoria possess every possible modern installation necessary to treat those invalids who seek a remedy for their ills. On

did M Emile Meyerson and M Georges Duhamel The latter wrote to Dr Vautier "Your work to save the youth is still in its infancy, and we are not able to measure its importance, but the day will come, perhaps, when you will have saved a Beethoven, a Descartes, a Shakespeare! That day, will the entire world know how to express its gratitude?"

Each student is permitted to carry on his work according to the system prescribed by his own university, with no limitations except those imposed by his conditions The patient spends a certain number of hours in bed or on a couch comfortably placed in the sunshine or well-sheltered balconies facing south where he is able to continue his university work. Each student who is confined to his bed is provided with a radio so that he may be in touch, not only with the outside world, but with proceedings in the lecture-room downstairs Other scientific equipment, laboratories, slide and film projectors, etc, are of the finest.

A large library and 160 magazines in different languages are at his disposal If one is interested in international work, it would be a gratifying sight to see these representatives of different nations working under the same roof as though they were one great family Their faces browned by the sun were beaming with happiness, showing that they had forgotten their illness in the great joy of going forward with their life-work Dr Vautier welcomes teachers from foreign universities if there is a vacant place for them

Dr Vautier's wife showed me their own little son, about two and a half years old, without a particle of clothing, playing with his toys in the sunshine on the balcony where he passes most of his young life. Nothing could be of more benefit to a child, starting life in perfect health, than to have the continual influence of the sun to assure his later physical well-being

On our way back, we passed Dr Rollier's stately new Factory Clinic, where men and women are afforded an opportunity to work at their respective trades, or learn a trade, and thus earn their daily bread while being cured

After dinner, we were served coffee on the balcony overlooking the mountains and the valley The sun was so warm that Dr Piguet opened a parasol to shield my head. Great flocks of choucass, graceful black birds smaller than crows, circled over the village below, adding a lively touch to the snow

The only completely air-conditioned trains to Florida and the South

the upper ridge of the mountain side is the Grand Hotel, its back against the great spruce forest and its face toward the sun and the Alps. Every comfort surrounds those who need to spend months here.

A winding road leads to the Mont Blanc Sanatorium, to which I was granted the favor of a visit by having a Swiss friend whose son, Dr. Charles A. Piguet, is the director. This sanatorium possesses every means for hastening the recovery of its patients. Radiography is applied on a large scale and by means of films, taken in series, the marvelous results obtained by treatment at a high altitude is observed and then further recorded in plastic form. Of the eighty patients spending the winter in the Mont Blanc Sanatorium under the skillful supervision of Dr. Piguet, about one fourth came to the dining room to enjoy the pleasure of a home table.

Dr. Rollier's Heliotherapeutic Establishments are famed for the treatment of all forms of tuberculosis of the bone, the joints, the glands, etc. The combined air and sun baths are known to be the most effective restorative. In 1910, Dr. Rollier opened the "Sun Preventorium," a school in the sun for delicate, predisposed children. "Les Noisetiers" is on the height at Cergnat near Leysin.

The home in which I was deeply interested was the Sanatorium Universitaire, the realization of a dream, the work of profound love on the part of the director, Dr. Louis Vautier. He conceived the idea of establishing a home for students when he realized the tragic sadness that envelops the mind of a student when, just as he is beginning his work upon which his future career depends, he finds that he has some form of tuberculosis.

Dr. Vautier consecrated all his forces, all his enthusiasm and his great love for youth to this noble work. Every Swiss university answered his appeal for support, every professor and student contributed a share, and today this noble work is a reality and carried on to a truly remarkable and encouraging degree of success. The sanatorium accommodates at present fifty students. There have been students from twenty nations who have come here for treatment and received the instruction given by professors who come from different universities.

These professors make regular visits and thus keep in close touch with the work. They often come for treatment themselves and thus have a prolonged stay there. Several professors have even come from France because of their deep interest in the work as

Sea air is good for convalescents

Doctors say that sea air, rest and good food build back health. Tiresome journeys are avoided by recommending the Half Moon, New York City's only ocean front hotel, a short half hour from Borough Hall, Brooklyn. Luxurious, modern accommodations at moderate rates are supplemented by these important features:

- SPACIOUS SUN DECKS ON OCEAN
- SALT WATER BATHS
- SPECIAL ATTENTION TO DIET
- FREE GARAGE FOR GUESTS
- BOARDWALK ROLLING CHAIRS

American Plan rates from \$5.00 per person

NEW RESIDENTIAL PLAN Special low monthly rates from \$32.50 per person (two in room) with salt water bath. Write for further details.

HALF MOON HOTEL Near Sea Gate, Brooklyn, N. Y. C.

David J. Martin, Managing Director

Phone Mayflower 9-3800

scene before us At our right, the charming Val d'Illiez with the Dent du Midi towering over it. A glimpse of the massive summit of Mont Blanc, the Dent de Morcles the Grand Mouveran, the Profile de Victoria, the Chamosaire, the Oldenhorn and the massive Diablerets, all covered with snow, the skiers across the valley shooting down the slide, leaping the ten-foot jump, the patients resting in the sunshine, the tranquility of the mountain peaks over all!

On our homeward journey, the sun lighted up the Dent de Morcles while the seven peaks of the Dent du Midi were enveloped in a cloud so thin that they were outlined against a blue sky and beneath them a sea of mist which, as we approached the valley, became rose-tinted and concealed the mountains

We were grateful for the sunshine and light which we left on the mountain-tops and also for that international understanding and friendliness that is rapidly taking possession of the hearts and minds of men.

Improvements at the "Laurel-in-the-Pines"

The Laurel-in-the Pines, in Lakewood, N. J., will open its 1936-37 season on Wednesday, November 25th, under the continued management of Frank Seiden. Outstanding among its many improvements for the new season is the \$20,000 expenditure for re-modeling the ballroom, to be called the Mirror Room.

In conjunction with the Mirror Room, the management has devised an entertainment program that includes a fine orchestra playing nightly and broadcasting over a coast-to-coast network and a special week-end floor show that will feature outstanding personalities of the stage, screen and radio.

For its initial program the Mirror Room will feature Joe Haymes and his Columbia Broadcasting orchestra, together with Barry

A luxurious berth for comfortable night travel on one of the new American Airlines Flagships

McKinley baritone and the gala holiday show will be headed by Belle Baker.

A diversified program of sports activities has been planned which includes fall golfing on the Laurel-in-the-Pines golf course and riding club, with a special bridle path for jumping, a shooting range and a dancing class for those interested in learning the latest novelty dance steps.

Negotiations are being made with the New Jersey Central Railroad for a special train to be added to the regular week-end trains to Lakewood for the exclusive use of the Laurel-in-the-Pines' guests.

* * *

Prepared for Busiest Winter in Air History

American Airlines Inc. developed the sleeper plane more than two years ago, and is the only domestic air line to offer such service. The early planes were twelve passenger "Condors" and they were used on the overnight services between Cleveland and Fort Worth, and Fort Worth and Los Angeles. They have been retired, however, and now the magnificent new fourteen-berth "Flagships" fly the Southern Transcontinental Route between New York and Los Angeles making only three stops between the coasts. The berths are luxurious six feet five inches long, and equipped with reading lights, ventilators, clothing hangers, etc.

Reversing the usual policies of the air transportation industry in facing winter operation, American Airlines Inc., is completing preparations for the busiest winter season in its history, A. J. Gariepy, district sales manager of the company, announced today.

Instead of curtailing schedules in anticipation of lessened traffic, American is adding

Golfing is one of the many attractions at Lakewood's "Laurel in the Pines."

schedules to its major routes throughout the United States and making available a greater number of passenger seats than ever before.

In New York alone, he pointed out, American Airlines today has in operation 35 3% more schedules than a year ago while the inauguration of overnight 14-passenger Flagship Sleeping Plane service to Los Angeles, and the installation of 21-passenger Flagships on the Buffalo-Detroit-Chicago route as well as on the New York-Boston division have made available 67 4% more seats than on November 1, 1935.

"Improved flight equipment and more modern aids to aerial navigation will enable American to maintain a higher degree of operating efficiency this winter than ever before," Gariepy said. "Realizing this fact, we have made preparations to accommodate an increasing flow of passenger traffic right through to spring."

Gariepy pointed out that the addition of co-pilots to planes in local service between New York and Cleveland via Albany, Syracuse, Rochester and Buffalo and also to Chicago via Washington, Elkins, (W Va.) Charleston, Cincinnati and Indianapolis will permit a greatly improved operation between these intermediate cities, complementing the high speed transports on the through service.

dancing and other social affairs. This hall has a seating capacity of approximately 5,000 and includes among its equipment a stage and committee rooms. A large arched loggia, 12 feet wide, overlooking the ocean, fronts this hall.

On the ground level are two splendidly equipped bath houses, 60 by 150 feet in area, each as large as the average dwelling house. Branch lines of the Pennsylvania-Reading Seashore Lines run direct to the Convention Hall on either side making it possible, should the need present itself, to discharge passengers almost on the beach itself.

One of the unique features of the main auditorium is a floor space of 90 by 200 feet, which can be converted into an ice skating rink in a comparatively short time. Hockey has been one of the outstanding sports at the Convention Hall during the past six seasons and two years the Atlantic City Sea Gulls won the national amateur hockey title. The ice in the rink can be melted in a few hours and the floor restored to its former condition.

Some idea of the immensity of the main auditorium may be gained from the fact that a 13-story building, 500 feet in length and 200 feet wide, might be erected within its walls, leaving a space of 100 feet on all four sides. The main auditorium is large enough to permit the playing of baseball and football games. Every fall turf is laid out and football played regularly at night on a regulation gridiron with special illumination that gives the entire place a daylight appearance. Seats for 12,000 are provided for football games and 41,000 for the major prize fights.

Within the main auditorium also has been constructed and fully equipped the largest stage in the world. It is 110 feet in width, 85 feet in depth and measures 165 feet between the wings. Located on the Pacific avenue side of the great structure, it has all modern properties, full electrical equipment and dressing room facilities, and on it may be shown to the best advantage the most spectacular of productions. It is on the huge stage that the professional basketball games and wrestling bouts are held during the season. For these events there is a seating capacity of 3,000.

The largest pipe organ in the world both in size and power, is housed in the main auditorium. Perfect acoustics comprise another outstanding feature of the main auditorium. Despite the Auditorium's immense proportions, the organ pipes have been so arranged at both sides of the stage and along the high, vaulted ceiling that the entire auditorium can be

An ancient land where enchantment lingers, mingling with modern sports and pastimes in a unique manner. And over all from November to April is the glamour of Egypt's superb climate, offering you Warmth, Comfort and Health through radiant sunshine.

"Duchess" Liners to Make Christmas Sailings to Europe

Christmas sailings from Canada, which means the last liners leaving Saint John, N. B., and Halifax in time to reach British ports before Christmas day, are always among the heaviest booked of the year. This time, as usual, it is necessary for the lines to schedule extra ships.

Actual "Christmas departures" this year for the Duchess of Richmond will be Dec. 11 from Saint John and Dec. 12 from Halifax, to Southampton and Havre. The Duchess of York, for Glasgow, Belfast and Liverpool, sails a day later from each port.

For those planning longer Christmas stays in the old country, the Montcalm sails from the two maritime ports Dec. 4 and 5 respectively.

In addition to the Christmas sailings from Saint John and Halifax, the last sailings from Montreal are always regarded as similar departures. In many cases the passenger lists on these occasions are also very large. Many of the passengers are from the western farmlands, homeward bound for a winter's visit.

Some, bound for the Continent, leave early to take in the Christmas Fair at Nuremberg, which starts Dec. 4 and lasts three weeks, the celebration of the Feast of the Immaculate Conception at the Notre Dame Church at Lyons on Dec. 8, or the St. Lucia Festival at Stockholm, Dec. 13.

No Cuts in Rates For Coronation

From the "Crows Nest," published by the Cunard White Star line, we learn there is no foundation to the rumor that reduced steamship rates will be in effect during 1937 in connection with the Coronation of Edward VIII on May 12, 1937.

Reports to the effect that steamship lines will make their rates as low as \$60 or \$80 per round trip are afloat, however, and agents are urged to discount them as fabrications of a harmful and confusing nature.

As it is anticipated that ocean travel to Great Britain and the Continent will be exceptionally heavy during Coronation year, this in itself will be a powerful enough attraction to visitors without the extra inducement of reduced rates.

* * *

Atlantic City's Convention Hall

This resort is justly proud of its convention hall, largest building of its kind in the world, and one of Atlantic City's greatest drawing cards in its appeal for visitors.

Constructed at a cost of \$15,000,000, the convention hall was erected on a more lavish scale than ever before attempted in this or any other country. Few visitors to the resort fail to take advantage of a tour of the huge building before returning to their homes.

Located on the Boardwalk between Georgia and Mississippi avenues, the structure covers an area of seven acres. It is 350 feet wide by 650 feet deep, and provides a total seating capacity of nearly 75,000, the main auditorium alone seating 41,000. This city's permanent population of 65,000 could be provided with seating accommodations in the structure with room to spare.

The housing of the largest of the national conventions is only one of the many uses to which this building is devoted. Hundreds of other attractions find their way into this superstructure throughout the year.

The floor of the main auditorium is 168,000 square feet in area, while an additional space of 100,000 square feet is provided in the basement. Adjacent to the main auditorium and fronting the Boardwalk is the ballroom measuring 130 by 185 feet, which may be used for smaller conventions, art exhibits, banquets,

flooded with melody graded to meet the needs of either large or small assemblages

The lighting of the Convention Hall is a veritable triumph of color and illumination. The hues of the sea and sky, mingled with gold predominate in decorative effects, and the lighting system is so designed as to merge them in a manner pleasing and soothing to the eyes. Through the medium of a new and original principle, the lighting of the stage and auditorium has been so designed as to permit not only the usual projection, spot lighting and special display of feature objects, but also, an unlimited showing of color effects.

The lobby leading to the Convention Hall has a vaulted passage 125 feet in length and 50 feet in width. The walls are of limestone with a ceiling of Gustavino tile and two tone terrazzo floor, with appropriate bronze enframements around the windows. Leading directly from this lobby and connecting with ramps to the upper and lower levels of the auditorium are roomy corridors.

An arcade containing 14 finely finished stores, stretches along the entire Boardwalk front of this massive structure. The stores are faced with marble and ornamental bronze enfacements and from the arcade leads an

entrance, 50 feet in width, to the interior of the Convention Hall. On the Pacific avenue side of the building there are additional stores, 21 in number.

Approximately 400 automobiles may be parked on the ground floor of this great structure. Terraced sidewalks have been provided on both Georgia avenue and Mississippi avenue in addition to the ramp inclines from the ground. By this means the huge crowds that on occasions fill the hall to capacity are handled with great expedition and dispatch.

Heat and ventilation are important items in a structure of this character, and experts in both these lines of endeavor found their work cut out for them when they set out to solve their respective problems. Air used for ventilation is again utilized to heat both the main auditorium and the smaller hall at the front of the structure. Direct radiation is used in the main entrance lobby, and entrances on the sides of the building, and is supplied by recirculating air warming units. The offices, stores, corridors, stairways, and other subdivisions of the building are heated by direct radiation.

For the maintenance of the required vacuum in the heating returns and for the disposal of air and condensation, six vacuum pumps are provided. The temperature throughout the entire structure is automatically controlled. Ventilation is provided by a battery of 31 motor driven fans, with a capacity of 1600 tons of air per hour. Also there have been installed 75 vent fans capable of discharging 2900 tons of air per hour. Seventy-two per cent of the air supplied to the building is for the main auditorium.

Because of the fact that the great national conventions and expositions which come here stage machinery and other exhibits, elevators capable of handling all kinds of heavy equipment have been installed. It was found necessary also to provide elevators for handling the chairs and scenery for the stage at the Pacific avenue end of the structure. Two large freight lifts of the vertical steel screw type, each having a capacity of 50,000 pounds, have been installed, in addition to a freight elevator of 4000 pounds capacity for trunks and light freight and a passenger elevator lifting 2000 pounds at the rate of 300 feet a minute.

Three Sterling water tube boilers of 1490 rated horsepower have been installed. This boiler plant provides steam for heating for hot water and for exhibition purposes. The oil used for fuel is stored in underground tanks of 40,000 capacity, so located that they may be filled from tank cars. Coal bunkers

have been provided, so that if the necessity arises a change may be made from oil to coal as fuel

The Convention Hall also houses the studios and offices of municipal radio station WPG, from which nearly fifty per cent of the nation's dance music broadcasts originate during the summer months

KNOX Clinical NOTES

SO many informative letters from practicing physicians reach my desk concerning the wide adaptability of gelatine in therapeutics, Knox Gelatine in particular, that I am presenting to you a few of the suggestions submitted

A New Jersey pediatrician writes that he has been using Knox Gelatine with satisfactory results for children who show lack of muscle tone. He insists on Knox Gelatine because it is high in glycine content. Knox Gelatine contains over 25% of this amino-acetic acid.

A Virginia doctor writes relative to the use of Knox Gelatine in muscular dystrophies. He says, "we have been getting some very nice results from it." The recommended dose of glycine for the treatment of muscular dystrophy and myasthenia gravis is 10 to 15 grams daily. This can be supplied by giving Knox Gelatine in palatable recipes containing as high as 10% of the product.

A Tennessee medical man tells us that in almost all asthenic conditions, especially muscular, whether the cause can be diagnosed or not, and regardless of other treatment and diet, he has the patient use Knox Gelatine in this manner. One of the four little envelopes (containing $\frac{1}{4}$ ounce) taken from a package of Knox Gelatine is dissolved in a little warm water. The glass is then filled with cold fruit juice and the patient drinks it at once. This gives almost 2 grams of glycine.

A new brochure entitled "Glycine Therapy in Muscular Dystrophy and Myasthenia Gravis" is now available. This contains, in addition to useful recipes, abundant clinical references, colored and plain illustrations of muscle-tissue involvement and other interesting material. Request a copy. Simply write to Knox Gelatine Laboratories, 474 Knox Avenue, Johnstown, N. Y.

ACID RESISTANCE

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

AMNIOTIN most effective in gonorrheal vaginitis

THE MOST RECENT of the increasing number of favorable reports concerning Amniotin is an article* discussing its use in gonorrheal vaginitis in children. The authors' conclusion is significant—"We consider the use of vaginal estrogenic suppositories the most effective method known for the treatment of gonorrheal vaginitis in children."

This is but one of many conditions in which Amniotin is clinically useful. Amniotin (physiologically tested estrogenic substance) is effective in the treatment of dysmenorrhea due to estrin deficiency, in the relief of menopausal symptoms, involutional melancholia, senile vaginitis, missed abortion, uterine inertia in labor, chronic nervous exhaustion, vomiting and nausea of pregnancy, and breast hyperplasia of the lobular type.

Amniotin is available in three dosage forms:

Amniotin in Oil (for hypodermic use)—10,000 International units per cc., boxes of 3 1-cc. all glass ampuls, 2000 International

units per cc., boxes of 6 and 100 1-cc. all glass ampuls

Amniotin Capsules (for oral use and for intravaginal use in infants)—1000 International units per capsule, boxes of 20 and 100 capsules

Amniotin Pessaries (vaginal suppositories)—2000 International units per pessary, boxes of 6 pessaries

Follutein—The anterior pituitary-like factor from pregnancy urine. It is useful in certain functional uterine bleeding, and, in the male, in the treatment of undescended testes and azoospermia. Supplied in 1-cc. vials containing 500 rat units and a 4-cc. vial of diluent, in 2-cc. vials containing 1000 rat units and an 8-cc. vial of diluent, and in a 5000-unit package.

Anterior Pituitary Extract—An alkaline aqueous extract of the anterior pituitary glands of cattle, contains the growth, thyrotropic and sex-complementary factors. Supplied in 10-cc. vials containing 100 growth units.

**DON'T JUDGE THE
RANGE OF THIS
OFFICE-PORTABLE
X-RAY UNIT BY
ITS SIZE**

BECAUSE the G-E Model "F" Office-Portable X-Ray Unit seems to you so extremely small in size, and its low price places it easily within your means, don't make the mistake of overlooking its practical diagnostic range and ability to produce radiographs of fine quality.

The principle of *complete* oil-immersion of both the high-voltage transformer and the x-ray tube in a single, sealed container accounts for this unusual compactness and high efficiency. Moreover, it makes the outfit absolutely shock proof under all operating conditions. . . If you have not yet taken the opportunity to see a practical working demonstration of the Model "F" in your own office, you cannot fully appreciate its possible advantages in your practice.

Fill out and mail this coupon requesting a demonstration. You need not feel obligated in so doing.

☐ Please arrange for an office demonstration of Model F Office-Portable X-Ray Unit

☐ Send literature describing the Model F Unit. 4512

VIOSTEROL

is produced with the most complete background of research and control, and is identified by the names of these five eminent American pharmaceutical companies: ABBOTT, MEAD JOHNSON, PARKE DAVIS, SQUIBB, WINTHROP

*For your free copy,
simply address the Foundation*

Based on six years' clinical experience with Viosterol preparations in the prevention of rickets, tetany and allied diseases, this invaluable little booklet—sent free to physicians on request—is certain to be read with interest by you and given a front rank position on your active reference shelf

A reprint from the Bulletin of the Johns Hopkins Hospital of "Calcium and Phosphorus Studies" by Shelling and Hopper, it contains findings of such vital import as—

"The value of effecting rapid healing is also of importance in cases of severe 'thoracic' rickets. It is in the loss of rigidity of the thorax that the essential danger lies, predisposing the children, as it does, to atelectasis and pneumonia. For this reason, it is essential to change the thorax from a collapsible bellows into one more rigid, with the least possible delay. We have found that Viosterol in moderately large doses accomplishes this adequately."

WISCONSIN ALUMNI RESEARCH FOUNDATION*

The "right before Christmas"—

Shop early! Shop early! Shop early!

Every year there is a repetition of a campaign waged to educate the shopper to do Christmas shopping early. But in spite of good intentions and resolutions, we all continue to be eleventh-hour rushers. We calmly resign ourselves to last-minute soaring prices, diminished varieties from which to choose, and even worse to the wear and tear of jostling and the infection-hazards of crowding.

Funny—is it?

Not very! We do practically the same thing at other times and with other things. We wait—, wait until necessity finds us handicapped for time and choice, until we leave ourselves prey to mistakes and oversights.

We know it's wrong and foolish to put off getting things done. Perhaps one of our Psychologists can explain why we persist in doing nothing about something until it has to be done. *But, perhaps you are the exception.*

If so, you don't wait until a broken limb is presented to you for mending before ordering splints. And you don't wait until the crisis in any case before thumbing through the NEW YORK STATE JOURNAL OF MEDICINE for information on how some one else saved their patient—or what product advertised might be of assistance at such a critical moment.

You *know* what should be done, what should be used, and how you can procure it with the least possible loss of time.

You *know*, because you are constantly watching advertising as well as text pages in your JOURNAL.

RICH IN IRON,
CALCIUM, PHOSPHORUS,
VITAMIN D—

Doctors find many uses for this delicious food-drink

THE use of Cocomalt by the medical profession continually increases. This delicious chocolate flavor food-drink has a rich content of Iron, Calcium, Phosphorus, Vitamin D. An ounce of Cocomalt (the amount used to make one glass) provides 5 milligrams of Iron in easily assimilated form. Three glasses provide 15 milligrams of available Iron, the amount recognized as the average daily nutritional requirement.

Each glass of Cocomalt in milk also provides 33 gram of Calcium, 26 gram of Phosphorus, 81 USP units of Vitamin D.

Helps bring sound sleep

Cocomalt is easily digested, quickly assimilated. It is delicious hot or cold, tempting to young and old alike. Taken hot before retiring, it helps induce sound, restful sleep.

Sold at grocery, drug and department stores in 1/2-lb and 1-lb air-tight cans. Also available in 5-lb cans for professional use, at a special price.

FREE TO DOCTORS:

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

R. B. Davis Co., Dept. 51 M, Hoboken, N. J.
Please send me a trial size can of Cocomalt without charge.

for pernicious anemia . . .

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

THE EXTENSIVE CLINICAL USE of this product during the past 18 months has demonstrated that pernicious anemia may be adequately treated by the use of this refined extract

According to our interpretation, adequate treatment implies the treatment of other disease symptoms aside from those referable to the blood (number of red cells, hemoglobin, cell volume) the gastro-intestinal tract (glossitis, diarrhea, loss of appetite) and the nervous system (peripheral and central)

Extensive neurologic involvement frequently requires intensive therapy over a long period of time to bring about improvement. In the presence of marked nervous system changes a large amount of active substance is indicated, far in excess of that required to bring about a complete blood remission. Infection and advanced age usually add to the requirements for active material.

Clinical experience of the last four years has definitely shown that parenteral liver therapy is the most effective and most economical method of treating pernicious anemia.

1 CC. CONCENTRATED SOLUTION LIVER EXTRACT *Lederle* offers many advantages to the physician and the patient

- Rapid improvement during relapse
- Maintenance with a relatively small number of injections per month
- A minimum of inconvenience to the patient with each injection
- Provides intensive therapy, still with little inconvenience, for those patients with extensive neurologic involvement

LEDERLE LABORATORIES, INC.
30 ROCKEFELLER PLAZA NEW YORK, N. Y.

This is the only Concentrated Liver Extract available in which 1 cubic centimeter contains active material obtained from 100 grams of liver

For a

BETTER UNDERSTANDING

of the therapeutic qualities of
the Bottled Waters of

SARATOGA SPA...

THE modern conception that liquids, like solids, have a molecular structure of definite spatial lattice form is of vital importance in interpreting the therapeutic qualities of the Saratoga Spa Waters. Each of these natural mineral waters possesses a definite molecular structure, presently impossible of duplication by an artificially prepared solution.

Herein lies a reason for the peculiar therapeutic qualities observed in thousands of cases by physicians and patients alike.

The State of New York bottles the waters of Geyser, Hathorn and Coesa Springs—three saline-alkaline waters of differing mineralization. All are super-saturated with natural carbon dioxide. Ingenious machines for bottling make it possible to maintain the therapeutically useful qualities of the waters in bottles, for an indefinite time.

Analysis of the Three Waters

(MINERAL PARTS PER MILLION)

<u>Hypothetical Combinations</u>	<u>Geyser</u>	<u>Hathorn</u>	<u>Coesa</u>
Ammonium chloride	61.17	59.10	38.77
Lithium chloride	27.00	64.49	42.43

Convalescents Require the High-Caloric Diet

COMMUNICABLE DISEASES		
Disease	Incubation Period (average)	Isolation Period (average)
Chicken Pox	12-16 Days	3-14 Days
Diphtheria	2-4 Days	After 12th Day— until cultures negative
Epidemic Meningitis	1st Week	Until cultures negative
Measles	2nd Week	Until 5 days from onset rash
Mumps	3rd Week	Duration of Swelling
Poliomyelitis	3-10 Days	21 Days
Rubella	3rd Week	Duration of catarrh and rash
Scarlet Fever	1st Week	After 21st Day— until cultures negative
Whooping Cough	2nd Week	Until 4 weeks from onset whoop

From
American Journal
of Public Health—
March, 1927

INFECTIONOUS FEVERS deplete the child's vitality. It is an exhaustion comparable to fasting. Convalescent children show a low metabolism for several weeks following the disappearance of the fever. The low metabolism is the consequence of generalized cellular damages.

When the infection clears, activity is curbed and rest periods instituted. The child is ready to gain. The problem is to bring about sufficient intake of food. The initial diet consists of small portions of each food prescribed and the amounts are gradually increased.

The high caloric diet is indispensable. It is made possible by reinforcing foods and fluids with Karo. Every article of the diet can be enriched with calories. A tablespoon of Karo provides 60 calories. Karo is relished added to milk, fruit and fruit juices, vegetables and vegetable waters, cereals, breads and desserts. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), not readily fermentable, rapidly absorbed and effectively utilized.

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. NM-12, 17 Battery Place, New York City.

CORRECTING FLAT FEET in children

**TARSO
SUPINATOR**

TARSO SUPINATOR represents the successful practical completion of an accepted theory in foot dynamics, accomplished in shoes

Features of the TARSO SUPINATOR SHOE—

- 1 No deforming pressure on fifth toe
- 2 Action is on the Tarsus—NOT on the metatarsus
- 3 Adducts the Tarsus by a powerful supinating action at the calcaneo-cuboid joint bringing the tarsus into a varus position thus raising the arch
- 4 A firm counter forms a fulcrum around which the foot is swung.
- 5 The heel of the shoe is brought forward on the medial side and raised one-eighth inch at its anterior border

Despite apparent over-correction, TARSO SUPINATOR SHOES present a normal appearance.

Designed for after treatment of CLUB FEET

**TARSO
PRONATOR**

PRONATING swing begins at the front of heel approximately at the astragalo-scapoid joint instead of acting merely as a metatarsal adductor

The pressure is distributed and applied at three points

- 1 Laterally directed pressure over the medial border of the first metatarsal a lever
- 2 Laterally directed pressure over the medial margin of the os calcis a lever
- 3 Medially directed pressure directed opposite the calcaneo-cuboid joint on the outer side of the foot a fulcrum

An elevation in the sole under the calcaneo-cuboid joint corrects so-called "rocker foot."

THE TARSO PRONATOR SHOE IS SUPPLIED SINGLY, IN PAIRS, OR SPLIT PAIRS, AS REQUIRED

Accepted Products

Products Which Stand Accepted by the Committee on Foods or by the Council on Pharmacy and Chemistry of the American Medical Association

If They Could Talk, Council Seals Would Say

"When you see one of us on a package of medicine or food, it means first of all that the manufacturer thought enough of the product to be willing to have it and his claims carefully examined by a board of critical, unbiased experts. We're glad to tell you that this product was examined, that the manufacturer was willing to listen to criticisms and suggestions the Council made, that he signified his willingness to restrict his advertising

claims to *proved* ones, and that he will keep the Council informed of any intended changes in product or claims. There may be other similar products as good as this one, but when you see us on a package, *you know*. Why guess, or why take someone's self-interested word? If the product is everything the manufacturer claims, why should he hesitate to submit it to the Council, for acceptance?"

Physiologic Effects of Benzedrine

Myerson, Loman and Dameshek (Am J Med. Sci Oct, 1936) report on the physiological effects of the sympathomimetic amine, benzyl methyl carbinamine ("Benzedrine") in adult humans. Administered parenterally in varying doses the average rise in systolic blood pressure was 29 mm of mercury. The height of blood pressure was attained in an average time of 46 minutes and reached its normal level 2 to 8 hours after administration. Orally in rather large doses (40 mg) the blood pressure increases were nearly identical with those after parenteral administration except that the action was delayed. Atropine when combined with Benzedrine markedly enhances its effects. A parasympathetic stimulant, mechohyl, when given with or during the period of Benze-

drine action, exerted its depressor effect over a shorter period, temporarily nullifying the action of Benzedrine without being antagonistic to its continued prolonged action. Benzedrine has a definite stimulating action on the central nervous system as shown by the shortening of sodium amytal narcosis. A marked rise in both white and red blood cells, with a lowering of color index, was usually found. These increases were apparently mechanical and of no clinical significance. The authors state that they did not observe an increase in basal metabolic rate or blood sugar. Reference is made to the good effects of Benzedrine in lowered mood and in certain fatigue states, these are the subject of a separate study, as is the drug's action in relaxing gastrointestinal spasm.—*Adv*

To be taken
twice a day at
Mealtime!

OUTSTANDING physicians today recommend baby foods with the same care they exercise in prescribing medicines. That's only natural. Strained foods and drugs share a common responsibility in infant welfare.

Equally understandable is the fact that more and more doctors are prescribing Heinz Strained Foods exclusively.

For one thing, each tin of Heinz Strained Foods bears the Seal of Acceptance of the American Medical Association's Council on Foods. And like the great names in phar-

maceuticals, Heinz Strained Foods carry a distinguished quality reputation—the heritage of almost 70 years unceasing effort to produce the world's finest pure food products.

To millions, this hidden value is expressed in the famous 57 Seal of Quality. Only Heinz Strained Foods possess it.

That is why we say, "Specify Heinz Strained Foods—for infants and other soft diet cases—twice a day at mealtime. You can be sure they will meet the most exacting demands for high nutrient content, easy digestibility and appetizing flavor."

Hospital Clean

BY BETTY LOU WILLIAMSON, R.N.

(It's worth two minutes to read it)

A few days ago, I had the pleasure, and I may say honor, of demonstrating the Nu Bidet to one of America's most outstanding urologists and gynecologists

The odd thing that impressed me was that he said more in praise of the Nu Bidet than I had the opportunity of saying, and he told me, before I could tell him, that it should be in every American home and hospital. So that made it unanimous

He agreed with me that far too few people are completely clean—clean as I have been taught cleanliness—hospital clean.

True enough, they take an external bath, never considering that an internal bath is equally, if not more, important to insure complete cleanliness and as a safeguard to health

Apart from personal hygiene, he saw at once the great advantages of the Nu Bidet in the treatment of urological, gynecological and proctological cases.

You, too, will be equally interested when you know more about the Nu Bidet. If you will use the coupon below, a very informative and beautifully done brochure, "Your Answer to a Long Felt Need," will be sent without obligation

The Nu Bidet is a complete unit of seat, Nu Bidet and lid in one assembly, which replaces the regular seat and lid. It is equipped with a specially designed and patented vacuum breaker and also a specially designed venturi siphon breaker making back siphonage or a cross connection impossible

WHAT IS THIS NU-BIDET? READ THIS!

The Nu Bidet is a thoroughly modernized Sitz Bath and more. The following uses make it a safeguard to health and as necessary to personal hygiene as your toothbrush or the bathroom itself.

Sitz Bath for personal hygiene and treatment of urological, gynecological and proctological cases. Spray for same purpose and feminine hygiene. Attachment for douche, enema and hydrotherapeutics entirely eliminating the old rubber bag method.

The Nu Bidet can be installed on any regulation size toilet bowl in less than two hours. It will convert the ordinary bathroom into one that is truly hygienic at a small investment. Use coupon now

We can make Immediate Deliveries

The Nu Bidet lifts up and stands against the lid when not in use

Nu Bidet does not change the appearance of your toilet. No extra space required

ELI LILLY AND COMPANY

FATIGUE AND NOISE IN INDUSTRYFOSTER KENNEDY, M D, *New York City*

Each age has its own genius and its own problems. While some of our headaches and sleepless nights will eventually push themselves into the past, we may be sure in things to come that new problems will come to tax man's wit. Just now we live in a period, Periclean *manqué* in a mad ingenious world full of poetry, murder, superstition, and mechanics. "This machine is to us" but we have emotions as well—maybe machines have too! It is emotion that makes a watershed between a fitting and smoothly running mechanical world and a more real world, complex in reactions and adjustments. Machines are made for man who should have the wit to control them for his own comfort and well-being. We deal here with industrialized man, on whom wear and tear increases with mounting inventiveness. Fatigue and noise in industry have been assigned to me for discussion—and thereby hangs for you and me a tale of trouble.

We cannot really here speak of fatigue from the point of view of workshop practice but from that of health. The former is the business of the industrial engineer and his army of experts with an eye for profits, the latter is the concern of the physician.

Objective fatigue comes when our muscles spend more than they repair—and how is this different from the quaint ways of the United States Treasury?

Subjective fatigue may be defined as the feelings of those who have to watch such antics, but Vernon, who seems a serious person, says that "if a worker suffers from excessive fatigue to the ex-

tent that his capacity to work is diminished, it follows sooner or later that he will experience subjective fatigue"¹ It's quicker to say that we can feel both muscular and mental fatigue.

Fatigue is in general influenced by circulation. Muscle fibers at rest secrete a reserve of glycogen ready to break down on stimulus² But too much importance has been attached to the accumulation of fatigue substances. We should stress a distinction between fatigue of excitation, or the consumption of substances that are necessary to life within the cell, and fatigue of depression or the accumulation of decomposition products, blocking function.³ Prolonged muscular exertion sets free carbon dioxide, lactic acid, acid potassium phosphate, and other by-products, which are dissolved in the blood stream. These decomposition products circulating in the system impair the functional activity of many tissues of the body.⁴ In extreme fatigue the glandular secretions are reduced by the accumulation of toxic products in the blood, and this stops digestion.

Fatigue in the nervous system is shown by a decreased excitability after previous excitation. The higher the center in the neural hierarchy the quicker it tires.⁵ Bronk,⁶ found that on the condition and activities of the sense organs in muscle depends the speed and efficiency of many organismal reflexes. This in animals Reid's study⁷ on man, using different weights, muscle contractions being marked by ergograph, demonstrated that afferent impulses from voluntary muscles are factors in producing fatigue in these

muscles regardless of whether the sensations are conscious or not

In a recent article, Cason, with experimental data, says fatigue is composed organically and is a failure to preserve an organic balance. He says

Fatigue is a local or general condition of impairment, and is the result of a variety of causes rather than the result of only one. Each of the different kinds of fatigue—such as conscious fatigue, unconscious fatigue, fatigue of the sense organs, fatigue of the nerves, fatigue of the muscles, chemical fatigue, neurasthenic fatigue, *et cetera*—has an organic nature

Commonly, several of the processes may be present simultaneously.⁸ Heavy muscular work reduces the capacity to perform other kinds of work, whether it be writing even a bad paper or playing billiards. Nevertheless a fatigued man may for a space perform work equal to a man rested—by adrenalization, acetylcholine or what we used, simply, to call will-power. Nevertheless there is loss of delicate coordination of movement associated with higher nerve centers, and there occurs much extravagant expenditure of muscular energy

The importance of rest pauses and changes in posture giving recovery from the effects of muscular exercise is indubitable. With the introduction of more frequent rests and changes of posture, and the holding of those positions demanding a minimum of mental, nervous, and muscular exertion, a larger amount of work may be done. In considering the pernicious results of poor posture, the Gilbreth International Committee advised the use of chairs constructed along anatomical lines and adjustable to individual workers.⁹

Methods of measuring fatigue in one industry are not always suitable for testing fatigue as it is experienced in another. There are certain indisputable evidences of fatigue, such as reduced production in the mid-morning and afternoon. In wartime, munition workers' output in Britain and America sagged at these times, and accelerated in both countries under sweet tea and ice-cream respectively. Tremor increases in spinners throughout the working day. If work continues over long, reaction time increases.¹⁰ By regulating his rate of output to the length of

his working period, the industrial worker may more or less unconsciously protect himself against fatigue. So, to shorten the working day usually produces improvement in the rate of output, but the variable factor is the honesty of persons and that varies with interest and self-interest. But the problem is not so simple that it can be solved just by shortening the working day, or like Mr. Ford, increasing the working wage. Among the chief factors causing fatigue we should include laborious work, piece work, speeding up, constant standing, irregular hours of sleep, eye strain, jarring processes, and loud noises which fatigue the ear and are conducive to deafness.¹¹ Overcrowding and bad air, particularly dryness and overheating, contribute to a feeling of tiredness and produce inefficiency.

"Fatigue," says Myers,² "is combated rather by the avoidance of too long uninterrupted spells of work, by the introduction of rest pauses, by change of work and posture, by determination of the best movements of the worker, by systematic training of the worker in these movements, by selection of the worker so that his occupation is adapted to his innate abilities, by the abolition of cause of needless resentment, irritation and worry, by the introduction of suitable incentives to work, and by the provision of good physical environment in regard to illumination, temperature, humidity, ventilation and food." And all these things together will perhaps be found in the New Jerusalem, Utopia, and the Never-Never Land of Dreams.

Closely related to the fitness of the work is monotony. Manifestly the primary cause of monotony in industry seems to be specialization of work and the minute division of labor. It may astonish you but it has been found by questionnaires that routine work is not necessarily monotonous. I asked many pitboys—miner's helpers—temporary soldiers—what they would do after the War—"go back to the pits," said they all. In our mundane mansions are many morons. Generally speaking, the more intelligent the worker, the more irksome becomes routine work. The maintenance of the required attitude becomes difficult because of his demands for more varied occupation. The results of a survey by Hop-

pock¹² suggest that the proportion of dissatisfied workers is probably less than a third. The presence of monotony is to be regarded subjectively, not objectively. Munsterberg¹³ became more and more convinced that the feeling of monotony depends much less upon the particular kind of work than upon the special disposition of the individual, and this despite the Demagogue's slogan that all men are created equal. Work production varies directly with zest. The nature of the work decides whether zest comes from the worker's intellect or his lack of intellect, workers of both kinds are needed for the world's work, but not for the world's government.¹

Of course the emotional tone greatly determines the development or absence of fatigue. This one saw well under War strain. During the ten day retreat of the British Fifth Army from the 21st of March 1918, the hospitals were filled with men so fatigued they could hardly stand. There were men who slept so sound that one could lift them up and drop them on the ground without awakening them. As the result of a victorious battle on the 8th of August of the same year, the British troops moved forward in attack to success, which ended on the 11th of November. During this period of no respite, full of zeal and impetus, when the men were so busy winning, they couldn't stop to get their hair cut, I saw practically no cases of physical exhaustion. When people are contented and happy, their productive ability and endurance are increased.

To this end, Mayo¹⁴ advocated development of social equilibrium and *esprit de corps* within industrial plants, here lies the worth of common aim and common understanding between capital and labor. It's a wise employer who girds his worker's morale, that the worker may gird up his loins.

Outside of industry, living conditions control fatigue, these are complex. The kind of food a man eats, the kind of rest he is able to obtain, the happiness of his home life, the temper of his wife, how often he laughs, these exert more than a superficial influence on his well-being. In a preliminary report¹⁵ the American Public Health Association concluded that a large proportion of illness among the in-

dustrial classes arises from respiratory and digestive causes and is not due to toxic material inherent in the course of occupation. A study of wage-earners for the Metropolitan Life Insurance Company by Dr. Louis Dublin, showed, among other things, that the industrial worker at the age of twenty had an expectation of life of forty-two years, as compared with forty-nine years for the non-industrial worker.¹⁶ This shortened life expectancy, shows that the causes producing this difference should be studied, especially the factors which surround the worker, environmental factors with a deeper influence on the general industrial population perhaps than has occupational poisoning.

Still, there can be little doubt that one of the most important predisposing causes of sickness and loss of time is fatigue arising from industrial work. "So tired," says Sir Thomas Oliver, "is an expression which should never be heard from any worker at the close of his or her work day. It signifies exhaustion." Hayburst, Director of the Division of Occupational Diseases of the Ohio Board of Health, listed as minor fatigue symptoms, tiredness, sore muscles, stiff joints, aches and pains, and more severe forms as muscular cramps, obstinate lumbago, wry neck, neuritis, neuralgia, and occupational neuroses.¹⁷ The worker has not much ground for complaint against fatigue to a normal degree, in the course of his work day as long as he remains in good health. Occasional short periods of sickness are more or less to be expected. To determine the actual extent of the adverse influences of fatigue on the health of the worker is not easy. It must be borne in mind that the ill-effects on health do not necessarily manifest themselves at once, their appearance usually is long delayed. Signs of chronic fatigue are loss of appetite, insomnia, indigestion, and gradually respiratory or cardiac derangements. The amount of sickness varies, of course, in different occupations. Ligament weakness, flat feet, round shoulders, dropped internal organs, and bowed backs are commonly observed in workers subjected to undue strain of these parts. In the American statistics of occupational diseases, the commonest fatigue affliction is tenosynovitis, especially of the tendons and sheaths about the wrist joints.

Among 1,217 cases of compensable occupational diseases reported to the Ohio State Department of Health during 1931, 166 (13.6 per cent) were due to tenosynovitis. It's not easy to appraise the role of fatigue in industry and without preliminary medical examination and if employers were wise they would require every applicant for a job to be examined medically, as does the Army and Navy—National employers. In the steady worker,¹¹ anemia, enlargement of the heart, increased blood pressure, circulatory disorders, kidney disease, neurasthenia, or nervous exhaustion may be caused by fatigue, but after all, these are also caused by life itself. However, no matter what part or parts of the organism are overworked, the brain and nervous system suffer.¹² Chronic fatigue predisposes to weakness, paralysis of parts, nervous breakdown, and exhaustion psychoses. Women, more liable to physical strain than men, have a higher sickness rate. Youth particularly is easier hurt than grown age. Growth is stunted, the dissipation of reserve force lead to deformities, a weakened constitution fosters a liability to chronic disorders. Relative to the importance of fatigue in its relation to accidents, some support the contention that more accidents happen during the later morning and later afternoon work.¹⁷ In 1911, Bogardus¹⁸ found that in the 2,678 accidents studied by him, fatigue was present in eighty-two per cent. Fatigue gives loss of muscular accuracy with a consequent increase of accident frequency. Have you ever contrasted your handwriting when rested and when tired? Vernon, however, working for the British Association Committee, stressed the influence of the psychical state of the worker in the causation of accidents and considered inexperience, lighting, and temperature as also responsible in part, as based on his observations in various factories.¹ Recent studies¹⁹ have shown the importance of rest periods in reducing accidents to workers in dangerous occupations. Informed opinion is that tiredness makes for accident.

There is little need to add that from the social aspect spending all a worker's energy on his job should not be required. If he employs all his powers on his task, he has none left for outside pursuits, to

which every man is entitled, and these may be—but often aren't, judging by the circulations of the yellowed journals—his higher life. After excessive expenditure of energy, mental processes become uniform and stereotyped.²⁰ Mechanical movements are done automatically and conscious attention is elsewhere. Loss of time from sickness, in which fatigue figures much, is economically of concern to the worker, as well as to the employer. The wage-earner's income is lessened and he and his family lose content and comfort.

Along with tiredness is noise. Today noise is listed in factory hazards with gases, fumes, dusts, toxic liquids, bacteria, and peculiar chemical and physical radiations. During the last five years there has been much probing of the problem of noise. Probably comment on the activities of the Noise Abatement Commission in New York has pushed the examination of mental and physical effects. It is somehow absurd that science should be called on to prove by theorem and decibels that noise annoys. Wealth of research has gone to prove the obvious in our streets and houses. However, when we regard noise in industry in relation to hearing, some controversy comes. Bartlett²¹ of the University of Cambridge, believes that only in highly selected and special occupations is there any evidence of serious damage to hearing caused by noise. Ten years ago, twenty-five noisy trades were listed in which workers were known to suffer from industrial deafness. Today the list may be extended. Frankel,²² working in nine heavy industrial plants in New York, found very little evidence of impairment of hearing without earlier history of bad ear conditions. Still, it must be noted that the group subjected to the greatest noise showed the greatest percentage of hearing deterioration.

Impairment of hearing, however, is insidious and at first hardly noticed, and we must accept the fact that hearing is reduced in many persons constantly exposed to very loud noises. But that this figure runs from this cause to sixty or eighty per cent of the population, as I read in a technical journal of last year, is frankly bosh. Printing has, of course, led to the multiplication, but fortunately

not the perpetuation, of many foolish statements. However, some auditory organs are badly damaged by prolonged exposure to loud noise.

Direct lesions of the internal ear caused by noise have been demonstrated by German investigators²⁵. In a pamphlet issued by the German Society of Industrial Hygiene, we are told that noise can impair hearing by intensity as well as duration. A single strong sound impression, such as a whistle or explosion, is particularly injurious if it occurs suddenly or unexpectedly, the auditory nerve endings in the cochlea may be damaged or the drum burst. Auditory nerve deterioration has also been demonstrated by Lurie, of Harvard, in recent research from continuous exposure to constant noise of loud quality.

The German report goes on to explain that not every human ear is injured by loud continual industrial noise. "The greater the power of resistance of the organism, and the healthier the organ of hearing, the less harmful is the effect of noise." Directions also are given there for the care of the ears, and protection is recommended by plugs of gauze saturated with petrolatum or wax. Apprentices and young workers are advised to have their ears examined by a specialist before beginning work in a noisy plant. During the period of employment, this examination should be repeated occasionally in order to find out if hearing is being impaired.

Very loud noise, as stated by Fowler in a New York Report, has a disrupting action in addition to a fatigue effect.

It may actually tear apart the drum membranes and the finer structures in the middle and inner ears. Hemorrhage from broken vessels, swelling from blocked circulation and degeneration of the nerve cells and fibers may occur.

This physical injury may cause deafness, head noises, dizziness and other distressing symptoms. In degree and permanence, injury is proportional to the intensity, duration, frequency, and suddenness of the noise wave impact, and the facility with which it passes into and through the middle and inner ears. Remember that every sound wave is a push and a pull, a squeeze and a suck of every tissue and structure through which it passes and upon which it impinges. The normal ear has a remarkable tolerance to intense sounds but once the critical or safety point is passed, injury follows. It is believed that one

of the causes of progressive deafness is overwork and strain of the defense mechanism of the ear, the mechanism which serves to protect the ear from loud noise.

Experiments with accurate hearing measurements in use at the present day confirm these statements but do not as yet give much information about the endurance of noises for months and years. Hence, the extent of the effects upon man cannot be quantitatively estimated.

Undoubtedly, progressive deafness in workers in noisy trades, such as boiler makers, should be included among work hazards to be compensated by insurance, and may come to be recognized as compensable affections. Protection can be given such workers, however, as was given in War to gun crews.

Considering the vibratory character of industrial noises beside the sound effect, excessive and prolonged as they are, it is readily understood that they not only disturb the ear mechanism but also jar the nervous system directly. Investigations of the physiologic effects on intracranial pressure were carried out in the Department of Neurology at Bellevue Hospital by means of a drum placed on skull defects in patients previously operated on, pressure variations were graphed. A sharp loud report produced a notable irregular disturbance and a rise in intracranial pressure to four times normal. A second noise caused a second peak in the curve. Constant noise excites and irritates, it alters conduct, it causes loss of temper, and plays a part in quarrels. To overcome the effect of noise, strain is put on the nervous system—leading to neurasthenic and psychasthenic states. But long before emotions are disturbed, others changes have taken place: heightened pulse rate, heightened blood pressure, and some irregularities in heart rhythm.

That disturbance may occur without the subject being conscious of it, is borne out by experiment. At the University of Michigan it was found that the noise of a passing taxicab raised the blood pressure of a sleeper—and sounds of rushing cars, sounds of hurry, by suggestion and association rather than by loudness, destroy equanimity.

Intense auditory excitation was reported by other investigators as directly

Among 1,217 cases of compensable occupational diseases reported to the Ohio State Department of Health during 1931, 166 (13.6 per cent) were due to tenosynovitis. It's not easy to appraise the role of fatigue in industry and without preliminary medical examination and if employers were wise they would require every applicant for a job to be examined medically, as does the Army and Navy—National employers. In the steady worker,¹¹ anemia, enlargement of the heart, increased blood pressure, circulatory disorders, kidney disease, neurasthenia, or nervous exhaustion may be caused by fatigue, but after all, these are also caused by life itself. However, no matter what part or parts of the organism are overworked, the brain and nervous system suffer.¹² Chronic fatigue predisposes to weakness, paralysis of parts, nervous breakdown, and exhaustion psychoses. Women, more liable to physical strain than men, have a higher sickness rate. Youth particularly is easier hurt than grown age. Growth is stunted, the dissipation of reserve force lead to deformities, a weakened constitution fosters a liability to chronic disorders. Relative to the importance of fatigue in its relation to accidents, some support the contention that more accidents happen during the later morning and later afternoon work.¹⁷ In 1911, Bogardus¹⁸ found that in the 2,678 accidents studied by him, fatigue was present in eighty-two per cent. Fatigue gives loss of muscular accuracy with a consequent increase of accident frequency. Have you ever contrasted your handwriting when rested and when tired? Vernon, however, working for the British Association Committee, stressed the influence of the psychical state of the worker in the causation of accidents and considered inexperience, lighting, and temperature as also responsible in part, as based on his observations in various factories.¹ Recent studies¹⁹ have shown the importance of rest periods in reducing accidents to workers in dangerous occupations. Informed opinion is that tiredness makes for accident.

There is little need to add that from the social aspect spending all a worker's energy on his job should not be required. If he employs all his powers on his task, he has none left for outside pursuits, to

which every man is entitled, and these may be—but often aren't, judging by the circulations of the yellow journals—his higher life. After excessive expenditure of energy, mental processes become uniform and stereotyped.²⁰ Mechanical movements are done automatically and conscious attention is elsewhere. Loss of time from sickness, in which fatigue figures much, is economically of concern to the worker, as well as to the employer. The wage-earner's income is lessened and he and his family lose content and comfort.

Along with tiredness is noise. Today noise is listed in factory hazards with gases, fumes, dusts, toxic liquids, bacteria, and peculiar chemical and physical radiations. During the last five years there has been much probing of the problem of noise. Probably comment on the activities of the Noise Abatement Commission in New York has pushed the examination of mental and physical effects. It is somehow absurd that science should be called on to prove by theorem and decibels that noise annoys. Wealth of research has gone to prove the obvious in our streets and houses. However, when we regard noise in industry in relation to hearing, some controversy comes. Bartlett²¹ of the University of Cambridge, believes that only in highly selected and special occupations is there any evidence of serious damage to hearing caused by noise. Ten years ago, twenty-five noisy trades were listed in which workers were known to suffer from industrial deafness. Today the list may be extended. Frankel,²² working in nine heavy industrial plants in New York, found very little evidence of impairment of hearing without earlier history of bad ear conditions. Still, it must be noted that the group subjected to the greatest noise showed the greatest percentage of hearing deterioration.

Impairment of hearing, however, is insidious and at first hardly noticed, and we must accept the fact that hearing is reduced in many persons constantly exposed to very loud noises. But that this figure runs from this cause to sixty or eighty per cent of the population, as I read in a technical journal of last year, is frankly bosh. Printing has, of course, led to the multiplication, but fortunately

PLOWING THE BABY CROP UNDER

The wholesale slaughter of little pigs and the wholesale plowing under of the tender crops is apparently being matched by the wholesale non-production of new citizens. We might almost say that the baby crop is being plowed under, along with the corn and the cotton.

A steady decrease in the fertility of American women is alarming students of population trends. Dr. Louis I. Dublin, vice-president of the Metropolitan Life Insurance Co., told an audience of women at the Child Study Association recently.

By the year 1980, unless new forces are brought to bear to increase the birth rate, 36 per cent of the population of the United States will be over 50 years old, Dr. Dublin said.

"And we're talking about old age pensions," he said. "Who's going to pay for them?"

The present excess of births over deaths—700,000 a year—is a misleading figure, Dr. Dublin said, because the population now includes "an unnaturally large number of women of child-bearing age, resulting from the fecundity of prior generations."

In a comparatively few years, he warned, there will be a sharp decline in birth rate and increase in death rate.

Birth control is the greatest single factor in bringing about this situation, he said, and its influence may be expected to grow.

An underlying cause, he said, is the shift of population from farms where children are an economic asset, to cities, where they are more of a liability from a financial standpoint.

There has been no decline in the marriage rate, Dr. Dublin said and, contrary to popular notion Americans marry younger now than fifty years ago. Though divorces have increased to a point where two out of every nine marriages terminate that way, it has not seriously affected the increase in population, he said.

"Believe me, the problem is keeping statesmen awake nights, both here and abroad," Dr. Dublin said. "In England they had more deaths than births in the first six months of this year. The fate of the race is a matter of serious concern to informed Englishmen."

"The same thing is true to a growing extent in this country."

"Unfortunately the most fertile areas from a population standpoint are those where schooling and standards of living are lowest."

"America will be compelled to replenish itself on a large scale from its backward areas."

"I am sure that fact lies behind the development of the Tennessee Valley Authority and other federal agencies doing similar work."

SECURITY OR INSECURITY?

The blessings of social security have hardly dawned upon America as yet, according to Lady Astor, M.P. who sailed for England the other day. Here is something to think about as we fill out our

tax-blanks. She said "Why, in England three out of every five pounds of a person's income goes to the Government for social security." Write your own comment.

increasing the arterial pressure, especially in the systolic phase. Smith and Laird,²⁶ experimenting on loudness of auditory stimuli, found that in four healthy human beings a decrease of thirty-seven per cent in the number of stomach contractions per minute results from eighty to ninety decibel stimulation. In some subjects there was a complete change in the type of contractions, and the size of the major contractions was considerably diminished. In a series of tests, Harmon²⁷ observed that unexpected and unfamiliar noise introduced during mental work, may increase the metabolic rate, heart rate, the breathing rate and volume.

Work in quality and quantity is not the same under noisy conditions as under quiet. In an investigation by Weston²⁸ into the performance of weavers under varying conditions of noise, it was shown that those who were partially protected by the use of ear defenders were able to attain a higher standard of efficiency than weavers of similar original proficiency exposed to the full clatter of the shed. On the other hand, Pollock and Bartlett²⁹ observed, in printing rooms, that many apparently harmful effects of noise tended to disappear as the workers became used to the condition of their occupation. Adaptation is aided by the uniform and rhythmic nature of certain industrial rackets—auditory or social—which are accepted as part of the working background of the task. Automatization of the task occurs and adaptation may be made fairly easily to such continuous noises of pure tone—but at a cost. Persons in good health can adapt themselves to harmful influences, nor do they realize energy and virtue is going out from them, that fatigue is on the way, and that toleration takes its toll.

The ability of the organism to adapt itself to noises of various kinds, as pointed out by E. D. Friedman, does not imply a lack of damage to the nervous system. He says

It speaks rather in favor of the great elasticity and adaptability of the human organism to various stimuli in its environment. It is not advisable to tax this elasticity too much.

More definite action should be taken to end or control industrial noises, much can be done. Sound absorbing materials, sound filters, silencers, balancing of rotating parts, particularly high speed ones, the mounting of machinery on anti-vibration supports or sound insulation of machines from buildings, proper distribution of machines, and various other methods and contrivances by which noise can be greatly reduced, have been developed by enterprising engineers. Some progress is seen in practical application. In the designing of new factory buildings today, devices for lessening noise are included. An acoustic consulting service in sound control, auditorium acoustics and noise abatement has been inaugurated by the Western Electric Company. The National Standards Association representing a number of technical organizations is studying the subject of acoustical measurements. These movements in industry toward noise prevention are signs of grace, kindness, and enlightened self-interest. The elimination of noise is profitable, so it begins to get some of the attention accorded to other problems such as lighting, heating, and ventilation.

The streets, too, are better though not yet sylvan meadows. The tintinnabulation of the milk wagons, the clatter of the emissaries of sanitation, the clangor of the brakes and horns have been a little lessened—And for this, much thanks. Only the hospital ambulances continue needlessly but sentimentally in their old wild raucous way, endangering about as much life and limb and happiness as they would likely salvage—and the volume of their hateful shrieking varies inversely with the importance of the institution they advertise—How long, Oh Lord, How long?

merely indicates that the individual is suffering from a disturbance of carbohydrate metabolism resulting in the faulty distribution of glycogen and fat. Because of the inability of the liver and muscles to store glycogen, the resistance of the patient is lowered, predisposing him to infection and increasing the risk in surgical procedures. Furthermore, the hyperglycemia may act as a culture medium in the presence of infections. Another interesting factor in the relationship of arteriosclerosis and diabetes is the fact that up to the present time no evidence of arteriosclerosis has been observed in the lesser circulation of diabetics, a fact which speaks against the idea that hyperglycemia is the cause of arteriosclerosis. I am therefore in full accord with the opinion of O'Hare,³ Moschowitz,⁴ and other investigators who regard hypertension as a predisposing factor in arteriosclerosis rather than hypercholesteremia and hyperglycemia.

Pick,⁵ in fact, has shown that arteriosclerotic changes in the eyegrounds occur ten times more often in hypertensive individuals than in individuals with normal pressure. Because of these opinions and findings, it was of interest to note the incidence of hypertension among diabetics.

Occurrence of Hypertension

To determine the incidence of hypertension in cases of diabetes, I made a comparative study of 243 diabetic cases and 938 non-diabetic cases as observed in my own private practice.

While we cannot with certainty state what the normal pressure of an individual may be, we have considered the systolic pressure from 120-150 mm of mercury as the upper normal limits above the age of forty.

As shown in Tables I and II, blood pressures below 150 occurred in a larger percentage (84.2%) of non-diabetics than in diabetic patients (69.5%). On the other hand, 17.3 per cent of the diabetic series showed pressures ranging from 151-170 and only 10.9 per cent in the non-diabetic series showed these pressures. Blood pressure ranging from 171-260 occurred in 13.2 per cent of the diabetics as compared with 4.9 per cent of the non-diabetics. In other words, systolic pressures above 150 were recorded in the present study in 30.4 per cent of the diabetic series and only 15.6 per cent of the non-diabetics. The greatest percentage of hypertension cases was found in diabetics between the ages of fifty and sixty.

It is of interest to note that these observations are in approximate agreement with those of Kramer,⁶ who noted a systolic pressure of 150 or more in thirty-nine per cent of his series of diabetic patients, the majority, as in the present series, occurring during the sixth decade. Kylin,⁷ Major,⁸ Joslin,¹ and Hitzburger,⁹ are among the observers who also noted a higher blood pressure in diabetic individuals of advanced years, than in a similar age group of non-diabetics. These findings substantiate my opinion and that of the other observers previously mentioned, that hypertension may account for the frequent occurrence of arteriosclerosis in diabetes because of its great incidence in this disease.

Relation of Hypertension

Because of the frequent occurrence of

ARTERIOSCLEROSIS AND HYPERTENSION IN DIABETES MELLITUS

JACOB SCHWARTZ, M D, Brooklyn

Physician Beth-El and Brooklyn Women's Hospital

The diabetic individual is known to suffer more from the complications of diabetes than from the disease itself. This statement applies not only to the pre-insulin era but is true at the present time as well. With the introduction of insulin, the management of the diabetic patient has been greatly simplified and results have been so satisfactory that today few patients are seen in diabetic coma. The danger of infection and the risk of surgical interference have also been minimized with the introduction of insulin to such a degree that the majority of surgeons do not hesitate to operate upon diabetic patients.

Increased incidence of Gangrene and Arteriosclerosis

It is remarkable, however, that simultaneously with the reduction of incidence of diabetic coma and other complications, an increased frequency of gangrene has been apparent, with a corresponding advance in the mortality rate. Whereas the mortality rate from diabetic coma has been lowered from sixty per cent, prior to 1914, to five per cent at the present time, the rate from the effects of gangrene has advanced from 2.3 to 10.4 per cent. Equally striking during this period has been the more frequent incidence of arteriosclerosis in diabetics. This rose from fifteen to forty-seven per cent.¹ This coincident increase in the occurrence of gangrene and arteriosclerosis would seem to suggest a definite relationship between the two conditions.

Diabetic gangrene appears to be the result of a gradual circulatory disturbance caused by arteriosclerotic changes in the extremities, rather than a result of the hyperglycemia. Many of my patients with severe hyperglycemia have not developed gangrene. On the other hand, patients with comparatively mild diabetes did

develop gangrene. This would indicate that the latter condition is probably the result of vascular changes and not of hyperglycemia.

If this is true, how are we to account for the presence of arteriosclerosis in diabetes?

Relation of Arteriosclerosis

1 Span of life It must be remembered that the span of life of the diabetic patient has been lengthened through the free use of insulin, thereby adding to the number of older subjects of that disease. Inasmuch as arteriosclerosis is present in the majority of older persons, an increased occurrence of arteriosclerosis in diabetic individuals is therefore to be anticipated.

While this accounts to a certain extent for the increase of arteriosclerosis, other reasons must be found to account for the great advance of arteriosclerosis among diabetics.

2 Hypercholesteremia This condition, heretofore regarded as a factor in promoting arteriosclerosis, has at the present time become a negligible factor through the use of insulin.

3 Hyperglycemia The question arises whether prolonged hyperglycemia induces arteriosclerosis. An analysis of my own cases showed that hyperglycemia occurred in varying degrees in diabetic subjects from 160-500 mg per one hundred c.c. of blood. The hyperglycemia in these cases was no index to the degree of arteriosclerosis found. Williams,² in a discussion of White's paper, reports a high blood sugar in a majority of his juvenile diabetics for the greater part of the time, over periods ranging from three to ten years. These children have developed normally and, according to Williams, have suffered no ill effects from the prolonged hyperglycemia. Similarly, I have found that the majority of older diabetic patients feel better with a blood sugar above normal. We very often see cases of cardiac pain caused by low blood sugar. It therefore appears that hyperglycemia, *per se*, is not harmful. It

Read Before the East New York Medical Society, May 6, 1935

Their findings agreed with Wilder's Warren,¹⁸ following a study of 156 consecutive autopsies on non-diabetic patients, arrived at the following conclusions

A. Practically any lesion found in the pancreas of the diabetic patient can be duplicated in the pancreas of non-diabetics

B. It is impossible from the study of the pancreas to diagnose the presence or absence of this disease. Therefore, one does not know how many cases are due to arteriosclerosis or other causes

While the preceding theories show the possibility of disturbed carbohydrate metabolism in certain hypertensive individuals, which may ultimately develop into diabetes if there is an anlage towards the disease, nevertheless, these theories do not wholly account for so many diabetics having hypertension

Preponderance of Hypertension in the Female

In a further study of my own patients, the following data has been obtained. As seen in Table II, in this series of 938 consecutive cases, the systolic pressure in 790 or eighty-four per cent of the cases ranged from 110 to 150. The distribution of sex was about equal in this group with the males slightly predominating. One hundred and two patients showed a systolic pressure ranging from 151-170. Among these were thirty-two males and seventy females, the proportions changing radically from that of the previous group with women now predominating approximately two to one. In the third group of patients whose systolic pressure ranged from 171-260, there was a total of forty-six, of which fifteen were men and thirty-one women, the ratio again being two to one.

The same thing held true among diabetic patients. As seen in Table I, pressures varying from 151-170 occurred in three males as compared to thirty-nine females. Blood pressures between 171-260 were recorded for six males and twenty-six females.

These observations would tend to demonstrate that there is a preponderance of hypertensive cases among members of the female as compared to the male sex, in both diabetics and non-diabetics. Correlating the fact that diabetes occurs more commonly in the female, in the above series the ratio was three to one, with

the fact that high blood pressure also occurs more often in the female, it is not difficult to understand the frequent occurrence of hypertension among diabetics, a fact which, I believe, has not previously been brought out in studies on the relationship of hypertension and diabetes.

In discussing the reasons for the high incidence of diabetes among women,¹⁹ I called attention to the fact that women suffer more often than men from endocrine and metabolic disturbances. The female is subjected to these disturbances during menstruation, pregnancy, lactation, menopause, and various infections such as puerperal and gall-bladder diseases. These conditions tend to lower the carbohydrate tolerance of the female, subsequently predisposing her to diabetes. The same theory, I believe, may help to explain the high incidence of hypertension among women. It is my opinion that there is no relation between hypertension and diabetes other than, as stated before, prolonged hypertension may lead to arteriosclerosis in the vessels of the pancreas and cause diabetes in a small number of hypertensive individuals, in just the same way as it may lead to cerebral sclerosis or sclerosis of the coronary or renal vessels, depending upon the region involved. The reason we see so many hypertensives among diabetics is because the disease occurs more frequently among women than among men and hypertension is also more common in women.

Relation of Persistent Hyperglycemia to Hypertension

Thirty-two diabetic patients were under my constant observation for a period of from two to five years, although the duration of the disease in these cases was many years. During this period (2-5 years), many blood pressure readings were taken, and a comparison of the blood pressure at the beginning of treatment and at the end of the period revealed these findings:

In seventeen or 53.1 per cent of these cases, the blood pressure was lowered, in five or 15.6 per cent of the cases the pressure remained the same, and in ten or 31.3 per cent the pressure had increased. A careful study of the charts of those patients whose blood pressure had gone up,

hypertension in so large a percentage of diabetics, many students in this field regarded hypertension as the precursor of diabetes. Some hold that increased blood pressure indirectly predisposes the individual to this disease, but others again, believe that persistent hyperglycemia influences blood pressure. Within the last two decades a rapid advance in research work has taken place in this country. This brought forward many new laboratory methods which are easily applied in clinical medicine. This has been produc-

epinephrin is produced in the medullary portion and not in the cortical portion of the gland, it is difficult to see how such an increase would be accounted for. However, Rabin¹² observed tumors in the medulla of adrenal glands in cases of hypertension which may be of significance in increasing the amount of epinephrin in the blood. Goldzieher,¹³ has shown that the adrenals are involved in the pathogenesis of hypertension, giving rise to a decrease in carbohydrate tolerance and resulting in hyperglycemia and diabetes in the sequence mentioned. The possibility that epinephrin may

tive of valuable information in cases of hypertension. O'Hare,³ was the first in this country to observe a lowering of the carbohydrate tolerance in persons with essential hypertension and he believed them to be potential diabetics. Herrick,¹⁰ in several studies, observed that 10-30% of his hypertensive cases showed hyperglycemia. Based on these findings, several theories have been presented to explain the coincidence of hypertension and hyperglycemia.

1 Metabolic theory. Herrick was of the opinion that the fact that hypertensive patients were formerly placed on high carbohydrate, low protein diets, and that these patients as a rule had a tendency to overeat, caused a strain on the pancreas and led to hyperglycemia and ultimately diabetes.

2 Hyperadrenalemia. Oppenheimer and Fishberg¹¹ collected from the literature fourteen cases of hypertension with tumors of the cortical substance of the suprarenal glands. This was interpreted as significant in increasing the epinephrin in the blood, a substance known to influence carbohydrate metabolism and arterial tension. But since

circulate in the blood in an inactive lipid combination from which adrenalin will split off under appropriate circumstances, has been suggested frequently, but was not substantiated in a recent extensive study undertaken by Wakerlin and Brunner.¹⁴ No significant vasoconstricting properties were found by these observers in the blood of hypertensive individuals.

3 Arteriosclerotic theory. Various writers, including O'Hare,³ Albutt,¹⁵ and Moschowitz,⁴ believe that prolonged hypertension will cause arteriosclerotic changes in the pancreas and particularly in the isles of Langerhans, lead to hyperglycemia and subsequently to diabetes. It is my opinion, however, that arteriosclerotic changes in the pancreas causing a disturbance of the carbohydrate metabolism, is the cause of diabetes in a very small percentage of individuals, because the severity of the disease does not correlate with the findings in the pancreas. This opinion is substantiated by the work of Wilder,¹⁶ who found that in most severe cases of diabetes, the pancreatic lesions were trivial and severe pancreatic lesions were frequently found in mild cases of diabetes. Gibb and Logan¹⁷ reviewed a series of 147 autopsy protocols

CURRENT TRENDS IN MEDICAL EDUCATION

WILLARD C RAPPLEYE, M D, *New York City*
Dean College of Physicians and Surgeons, Columbia University

Current trends in medical education in the United States can best be evaluated in the light of the changes which have occurred in this field of professional education in the last thirty years and the growing appreciation of the wider responsibilities of medicine as an agency of community as well as of individual health. It is not always appreciated that nation wide recognition of proper standards of medical training and licensure is of recent origin. A few universities have maintained excellent schools of medicine for many years but until only a short time ago a large majority of the schools were proprietary and in many instances commercial institutions.

One need only examine the demands of the various state boards for licensure to get a picture of the minimum requirements of medical education. In 1904, for example, only twenty states had any requirements of general education whatever and only ten of them required graduation from a high school. No state demanded any college training preliminary to the medical course which in many schools at that time was only three years in length. The responsibility of protecting the public from ill-trained and unqualified physicians, the rapid development of the medical sciences, and the recognition of the dependence of sound clinical medicine upon the principles of those sciences brought about a remarkably rapid elevation of the standards of medical education in the brief span of three decades.

In the process of elevating the standards of medical education it was necessary to establish rigid, detailed requirements to permit the enforcement of those standards. Many of these requirements became crystallized into rules, regulations, and law. The inevitable result was rigidity and a deceptive uniformity in a field of knowledge that has been going through

phenomenal growth. At no period in history have there been such rapid additions to knowledge regarding disease and health. Medical faculties and licensing bodies endeavored to add new subjects as they developed and to institute new requirements and examinations so rapidly that great overcrowding of the curriculum and a body of external regulations resulted which have made it very difficult to adapt medical training to meet changing needs.

We are now in the midst of a new phase of medical training based upon a wider appreciation of the fact that medical education is governed by the same principles as other fields of education and by a deeper appreciation of the larger public and social responsibilities of medicine. It is now widely recognized that the premedical student, the medical student, the intern, the hospital resident, the general practitioner, the specialist, and the public health administrator are, from the educational point of view, merely different phases in the training of personnel for the care of the sick and the preservation of health. Medical education, therefore, cannot be regarded as independent of general education on the one hand and of the professional needs of the community on the other.

Time will not permit a discussion of premedical education beyond emphasizing the fact that that period should not aim to be preprofessional in character but rather to provide opportunity for the student to secure a broad cultural education. The selection of students for medicine should be based upon the individual qualifications of the student and not merely on the length of his preliminary education, his grades, or the subjects which he may have taken in college. After all, the purpose of a medical training, broadly conceived, is to prepare a cultured and edu-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

showed that the average increase was about ten points. Furthermore, in most of these cases there were other factors present such as cardiac involvement, nephritis, etc., which might have been responsible for the increased pressure.

Mosenthal²⁰ studied several patients for a period of seven years to determine the influence of blood sugar upon blood pressure and has concluded that hyperglycemia does not increase blood pressure. In the light of these findings, I have definitely come to the conclusion that at the present time there is no evidence to indicate that prolonged hyperglycemia bears any relation to hypertension.

Conclusions

1 Arteriosclerosis and not hyperglycemia is the cause of gangrene in diabetic individuals.

2 Hypertension is more common among diabetics than among non-di-

betics. In this series, 30.4 per cent of diabetic patients showed a blood pressure above 150 while only 15.6 per cent of non-diabetics showed a blood pressure above 150.

3 Hypertension occurs more often in the female than in male individuals. The ratio in the series of non-diabetics was two to one, diabetics was three to one.

4 It is my belief that no relation exists between hypertension and diabetes. However, hypertension may be an indirect factor in the causation of diabetes. Prolonged hypertension may cause arteriosclerosis involving the vessels of the pancreas and cause a disturbance in the internal secretion of the pancreas and result in diabetes.

5 According to my findings, hyperglycemia cannot be considered a factor in the causation of hypertension.

OXFORD'S MEDICAL WINDFALL

Lord Nuffield, the British motor manufacturer, has given \$6,250,000 to Oxford University for the establishment of a post-graduate medical school—the largest single gift, it is said, by an individual donor to any British university. There is already at Oxford an Institute of Medical Research on a small scale, founded by Lord Nuffield, and he has made generous gifts to Oxford hospitals. He has also just given \$400,000 to Guy's Hospital to enlarge the nurses' home. As quoted in the *London Times*, he says of his Oxford gift:

I realize that progress in medical science is reaching a stage where it is desirable for those who work in the field of research to undergo a period of post-graduate training in modern methods of investigation, to keep in close touch with developments in the sciences ancillary to

medicine, and to pursue their inquiries unhindered by the cares of private practice and of routine teaching.

In regard to medical practice, I welcome the increasing tendency to regard all health services, preservative, preventive, and curative, not as separate entities but as constituent parts of a combined effort to promote and maintain the good health of the community. It is specially gratifying to me to learn that attempts to give effect to this ideal are being made in Oxford. Thence it is an easy step to the conception that the presence of a post-graduate medical school in a university town in which all the scientific departments are within easy reach of the hospitals, and in which coordination of health services will, I hope, be soon established, would improve the position and the facilities of those already engaged in clinical work in either institutional or general practice.

CURRENT TRENDS IN MEDICAL EDUCATION

WILLARD C RAPPLEYE, M.D., *New York City*
Dean College of Physicians and Surgeons, Columbia University

Current trends in medical education in the United States can best be evaluated in the light of the changes which have occurred in this field of professional education in the last thirty years and the growing appreciation of the wider responsibilities of medicine as an agency of community as well as of individual health. It is not always appreciated that nation wide recognition of proper standards of medical training and licensure is of recent origin. A few universities have maintained excellent schools of medicine for many years but until only a short time ago a large majority of the schools were proprietary and in many instances commercial institutions.

One need only examine the demands of the various state boards for licensure to get a picture of the minimum requirements of medical education. In 1904, for example, only twenty states had any requirements of general education whatever and only ten of them required graduation from a high school. No state demanded any college training preliminary to the medical course which in many schools at that time was only three years in length. The responsibility of protecting the public from ill-trained and unqualified physicians, the rapid development of the medical sciences, and the recognition of the dependence of sound clinical medicine upon the principles of those sciences brought about a remarkably rapid elevation of the standards of medical education in the brief span of three decades.

In the process of elevating the standards of medical education it was necessary to establish rigid, detailed requirements to permit the enforcement of those standards. Many of these requirements became crystallized into rules, regulations, and law. The inevitable result was rigidity and a deceptive uniformity in a field of knowledge that has been going through

phenomenal growth. At no period in history have there been such rapid additions to knowledge regarding disease and health. Medical faculties and licensing bodies endeavored to add new subjects as they developed and to institute new requirements and examinations so rapidly that great overcrowding of the curriculum and a body of external regulations resulted which have made it very difficult to adapt medical training to meet changing needs.

We are now in the midst of a new phase of medical training based upon a wider appreciation of the fact that medical education is governed by the same principles as other fields of education and by a deeper appreciation of the larger public and social responsibilities of medicine. It is now widely recognized that the premedical student, the medical student, the intern, the hospital resident, the general practitioner, the specialist, and the public health administrator are, from the educational point of view, merely different phases in the training of personnel for the care of the sick and the preservation of health. Medical education, therefore, cannot be regarded as independent of general education on the one hand and of the professional needs of the community on the other.

Time will not permit a discussion of premedical education beyond emphasizing the fact that that period should not aim to be preprofessional in character but rather to provide opportunity for the student to secure a broad cultural education. The selection of students for medicine should be based upon the individual qualifications of the student and not merely on the length of his preliminary education, his grades, or the subjects which he may have taken in college. cated gentleman and not merely a technician

In passing, one comment may be made about the great number of students applying for admission to medical schools. This situation is not confined alone to the medical profession but exists in all other fields of higher education. It must be borne in mind that during the last forty years, while the population of the country has increased about ninety-five per cent, the number of graduates of the so-called institutions of higher learning have increased about 770 per cent. In other words, the graduates of these institutions have increased eight times as rapidly as the population. It is inevitable that great pressure of numbers should be brought upon the medical schools, which in the last thirty years have been reduced from one hundred and sixty-two institutions to sixty-seven approved four year schools.

The objectives of undergraduate medical education, of which the internship should be regarded as a part, are to equip the qualified student to begin the practice of general medicine or the pursuit of advanced training and to equip him to continue his own self education throughout his professional life. The undergraduate course of study can only begin the education of the physician for he must remain a student all his life if he is to discharge fully and to his own satisfaction the responsibilities which will fall upon him.

The student should not only be prepared in the necessary technical training and scientific critique but he should also be imbued with a proper attitude toward his professional and public responsibilities and be able to give sound advice on the various problems presented by the patients who come to him, which of necessity requires that his training be based on a broad and sound foundation. It is important that the training be permeated with an understanding of the social and economic problems and trends with which medicine must deal and which are likely to influence the forms and opportunities of practice in the future.

While it is highly important that the purely intellectual talents of the student should be developed to the fullest, it is equally necessary that the qualities of temperament, human sympathy, and insight which are required for dealing with

the manifold human problems of medical care should be emphasized. The physician needs an understanding of, and must be able to treat, the man as well as the disease. Probably no field of endeavor comes closer to the everyday problems of humanity than medicine. Instinct, experience, and judgment in dealing with human affairs are essential for the physician and cannot be made a part of any formal scheme of education but must come from example, precept, and that unselfish devotion to the care of the sick and unfortunate which has been the tradition of medicine throughout the ages.

The success which a physician may obtain is determined in large measure by his personal qualifications, among which the most outstanding are integrity, industry, judgment, resourcefulness, and common sense. These qualifications are largely individual and apart from those of previous formal education and training. They emphasize the fact that many of the qualities of the real physician are additional to his purely intellectual and technical abilities.

These considerations make it clear that the level and objectives of medical training are governed in large part by the qualifications of the students who are admitted to the professional training. It is generally recognized, however, that the type of student who studies medicine, as in any other profession, is determined to a considerable extent by the professional opportunities and the social recognition of the physician in the community, which emphasizes further the broad underlying influence of the social and economic factors in medicine.

The concept of what the medical course should attempt to provide is changing. In the past the effort has been made to acquaint the student, as far as his time, energy, and capacity permitted, with as many facts, methods, and diseased conditions as could be presented in the schedule assigned. Because of the limitations of time this necessarily meant the demonstration of many conditions in a didactic manner. The present attitude is to prepare the student to study and appraise the nature of the disturbance present in a given patient, whether it be physiological, psychological, emotional, or social, for it is upon a correct understanding of the

disturbance in the patient that rational diagnosis and treatment must be based. Instruction of this character can be accomplished in the time available only through the intensive study of a limited number of conditions illustrative of the principles involved.

The enormous increase in knowledge, the widening public responsibilities of medicine, the development of various technical procedures for diagnosis, treatment, and prevention make it evident that the basic course cannot provide a student with an adequate knowledge and experience in all phases of medical science and practice. The hope of presenting the entire subject satisfactorily in the usual course must be abandoned as an unnecessary and futile endeavor because no individual can be expected to master all phases of medicine. A subdivision of labor in medical service is inevitable and desirable.

The amount of knowledge and scientific accomplishment which can be secured in a reasonable period of training by students of different types, capacity, and preparation is limited. The aim should be to provide each student with an adequate body of knowledge and a supervised experience sufficient to allow him to begin the practice of medicine with safety or to serve as a foundation for subsequent graduate education. In seeking to accomplish these purposes, emphasis should be kept constantly upon the fact that the degree of scientific interest and the methods and habits of thought attained by the medical student determine to a considerable extent the level of his future practice and his capacity for intellectual growth.

Some have believed that the elevation of undergraduate medical training to a high level would largely solve the problems of keeping physicians abreast of new developments and would insure that the public receive the best of care. It is generally appreciated, however, that even at best the undergraduate training can deal only with the elementary and introductory principles of medicine. The mass of scientific knowledge and experience is far too great to be covered in detail in any course. Furthermore, knowledge is not static. Each year many new discoveries are brought forward, some of which occasionally modify the concepts of disease as well as treatment and prevention.

Keeping physicians aware of and competent to use the best current knowledge is one of the most important features of a satisfactory medical service for the country. The continued education of physicians in practice is an essential feature of an adequate health program.

The great need of the country is for better, not more, physicians and for opportunities for those in practice and those who are qualified to specialize to prepare themselves adequately for their responsibilities to the public. A widespread and permanent improvement in the quality of medical service cannot be secured until graduate medical education has been developed at least to the level of excellence of the better undergraduate courses and has been closely articulated with the basic training. The public is confused by the large number of doctors who claim to be specialists whereas, in reality, there is a shortage of properly trained experts to meet the medical needs of the country. Present facilities and opportunities are quite inadequate for the training of a sufficient number of properly qualified specialists, although the number of hospitals and laboratories in which such training may be given is sufficient if educational supervision and direction can be secured. Only a few institutions now provide what may be regarded as a thorough preparation for a specialty.

There are indications that there will soon be developments in graduate medical education that will be as far reaching and vital to the public welfare as those which have been witnessed in undergraduate training during recent years. The different groups of specialists have organized national boards for the purposes of determining qualifications for admission to the various specialties and of publishing lists of qualified specialists. An Advisory Board for Medical Specialties, in conjunction with the program of the American Medical Association, has been organized to assist in establishing uniformly high standards and in coordinating the activities of these boards. As a result of these efforts a national Register of Specialists can shortly be created, admission to which will be based on a training and experience in each limited field of practice which may be regarded as sufficient to insure proper protection of the patient and the public.

cated gentleman and not merely a technician

In passing, one comment may be made about the great number of students applying for admission to medical schools. This situation is not confined alone to the medical profession but exists in all other fields of higher education. It must be borne in mind that during the last forty years, while the population of the country has increased about ninety-five per cent, the number of graduates of the so-called institutions of higher learning have increased about 770 per cent. In other words, the graduates of these institutions have increased eight times as rapidly as the population. It is inevitable that great pressure of numbers should be brought upon the medical schools, which in the last thirty years have been reduced from one hundred and sixty-two institutions to sixty-seven approved four year schools.

The objectives of undergraduate medical education, of which the internship should be regarded as a part, are to equip the qualified student to begin the practice of general medicine or the pursuit of advanced training and to equip him to continue his own self education throughout his professional life. The undergraduate course of study can only begin the education of the physician for he must remain a student all his life if he is to discharge fully and to his own satisfaction the responsibilities which will fall upon him.

The student should not only be prepared in the necessary technical training and scientific critique but he should also be imbued with a proper attitude toward his professional and public responsibilities and be able to give sound advice on the various problems presented by the patients who come to him, which of necessity requires that his training be based on a broad and sound foundation. It is important that the training be permeated with an understanding of the social and economic problems and trends with which medicine must deal and which are likely to influence the forms and opportunities of practice in the future.

While it is highly important that the purely intellectual talents of the student should be developed to the fullest, it is equally necessary that the qualities of temperament, human sympathy, and insight which are required for dealing with

the manifold human problems of medical care should be emphasized. The physician needs an understanding of, and must be able to treat, the man as well as the disease. Probably no field of endeavor comes closer to the everyday problems of humanity than medicine. Instinct, experience, and judgment in dealing with human affairs are essential for the physician and cannot be made a part of any formal scheme of education but must come from example, precept, and that unselfish devotion to the care of the sick and unfortunate which has been the tradition of medicine throughout the ages.

The success which a physician may obtain is determined in large measure by his personal qualifications, among which the most outstanding are integrity, industry, judgment, resourcefulness, and common sense. These qualifications are largely individual and apart from those of previous formal education and training. They emphasize the fact that many of the qualities of the real physician are additional to his purely intellectual and technical abilities.

These considerations make it clear that the level and objectives of medical training are governed in large part by the qualifications of the students who are admitted to the professional training. It is generally recognized, however, that the type of student who studies medicine, as in any other profession, is determined to a considerable extent by the professional opportunities and the social recognition of the physician in the community, which emphasizes further the broad underlying influence of the social and economic factors in medicine.

The concept of what the medical course should attempt to provide is changing. The present attitude is to prepare the student to study and appraise the nature of the disturbance present in a given patient, whether it be physiological, psychological, emotional, or social, for it is upon a correct understanding of the

LATE EXTRA-UTERINE PREGNANCY

H HUDNALL WARE, JR, M D, F A C S, *Richmond, Virginia*
From the Department of Obstetrics, Medical College of Virginia

Eight patients with extra-uterine pregnancies of more than thirty-four weeks duration have been admitted to the wards of the Hospital Division of the Medical College of Virginia since December 1930. We feel that this complication is of sufficient interest to justify a brief report of these cases and some of our observations concerning them.

Four of these patients had intraligamentous pregnancies of eight, ten, eleven, and thirteen calendar months duration. From the histories of these women, it seems probable that in three, the fetuses were viable until at least forty weeks after conception. All four fetuses had died before the patients were examined by us. One probably died about the sixth month.

Four women had abdominal pregnancies of thirty-six, forty, forty-one, and forty-four weeks duration. Two of these women were delivered of normal living babies. Death of the fetuses had occurred prior to hospitalization of the other two.

Two of the eight patients have previously been reported by the author. Both have subsequently been delivered of intra-uterine pregnancies, and another of this group is now about twelve weeks pregnant. Our observations warrant a review of their histories.

Seven of the women were admitted to our service and operated upon by the author. Six of these lived and one died. One patient was admitted to the service of the late Dr G. Paul LaRoque. She was operated upon by him, but died a few days later. The baby from this patient lived.

CASE 1 L I (intraligamentous pregnancy forty-two weeks duration), negro, twenty-five years old, married seven years, had one living child and one stillborn baby. She was referred by her physician because of prolonged difficult labor and vaginal hemorrhage for three days.

Her abdomen was distended to the size of a term pregnancy. A globular mass the size of a large orange was palpated to the right of the midline, and just above the symphysis pubes. It contracted at five minute intervals, the patient complaining of pain during the contractions. Fetal small parts were palpated posterior to the above mentioned mass and just above the umbilicus. No fetal heart sounds were heard. On vaginal examination the cervix was long, soft, and eroded. The external os was closed and lacerated a little. The cervix was continuous with the contracting mass in the right lower quadrant. X-ray examination confirmed the presence of a dead fetus. Extra-uterine pregnancy was diagnosed. Under spinal anesthesia, the abdomen was opened through a right paramedian incision. The body of the uterus was enlarged to the size of an orange, being pushed anteriorly and to the right. The pregnancy was in the left broad ligament. A macerated fetus, the size of a term pregnancy, was removed. The placenta was attached to the base of the broad ligament, and could only be partially removed because of its attachment over several large blood vessels. The intraligamentous cavity was packed with gauze to control hemorrhage and the edges of the broad ligament were sutured into the lower angle of the abdominal incision for drainage. The upper portion of the incision was closed without drainage. The gauze packing was entirely removed by the seventh day. This woman's temperature remained around 100°F for twenty-eight days. The abdominal sinus continued to drain a little during this time. She had no urinary symptoms and no abdominal distention.

This patient has recently had a normal intrauterine pregnancy and after fourteen hours labor delivered spontaneously a living normal female child which weighed seven pounds. Her convalescence was uneventful and temperature remained normal.

CASE 2 P W (intraligamentous pregnancy eleven months duration), married, negro, thirty-four years old, had never been pregnant before. She was referred by her

These general considerations are producing certain changes in the medical course proper. Perhaps one of the most significant of these is the growing emphasis upon the fact that the basic training is a unit, not a series of isolated and unrelated subjects and that the specialized features of training should be developed in the graduate program. There has long been a tendency to regard the medical course as a series of independent subjects but it is now recognized by some faculties that the entire training is itself a unit. It is on this basis that the correlation of teaching, joint exercises between different departments, and comprehensive examinations, as examples, have been introduced rather widely.

Another aspect of importance is the endeavor to individualize instruction and to place responsibility as far as practical upon the student for his own training. This is an endeavor to develop in the student sound methods and habits of study which will equip him to continue his own self education after graduation. The individualization has taken the form of small sections, seminars, conferences, study periods, clinical clerkships, the case method of instruction, and various other devices of this character, in contrast with earlier methods of teaching largely by lectures, demonstrations, and amphitheater clinics. It is widely recognized that many phases of medicine cannot be taught by the faculty, they must be learned by the student under direction in order to give him that body of knowledge and skill which accumulated experience has emphasized as necessary for the sound practice of medicine. This attitude emphasizes the fact that the student is the unit of education, not the curriculum or the faculty, important as they are, and places greater stress upon the opportunities for learning and for the development of self-reliance, judgment, and resourcefulness.

Many diseases and disabilities are known to be preventable. An increasing proportion of instruction places emphasis upon this aspect of medical care for it is well-known that a sound knowledge of anatomy and physiology is a basis of preventive medicine quite as much as it is

a basis of disease and abnormality. An effort is made in the course to equip students so that they may be able to render a competent service of prevention and of treatment to families as well as to individuals.

Probably the most defective part of medical training today is the internship. Internships are usually intended to provide resident services for the hospitals without due regard to the educational needs of the student. Changes being made in the medical course proper will require readjustments in the internship, which should be more closely articulated with the period of formal instruction if the best results are to be expected.

Sound medical care requires that the physician understand the importance and influences of social, economic, and psychological factors as they are related to the problems of health. Not much is given in the usual medical course in the way of formal instruction in these matters, but students are brought in daily contact with the social and economic aspects of medicine in the hospitals, clinics, social service, nursing, and other programs, and they are securing considerable appreciation of the importance of these phases of medical care.

The placing of medical education under the supervision and in the atmosphere of the university is leading inevitably to a wider interpretation of the responsibilities of medicine in a modern society and is making available knowledge and research from a number of other fields of knowledge which have a bearing upon the patient in his emotional, economic, social, and spiritual life as well as in those fields which in the past have been largely restricted to the medical sciences. It is this larger point of view regarding the functions and responsibilities of medicine in community life and the application of sound principles of education to the needs of medical training that perhaps will have the widest influence in shaping and focusing the objectives of medical training and which promise to make our profession of even greater importance in modern civilization.

normal, child living Her second pregnancy terminated in an early spontaneous complete abortion

When admitted to the hospital, she was about forty weeks pregnant. She had no history of any discomfort or pain and no symptoms except constipation until four days before hospitalization, when intermittent abdominal pains occurring every twenty minutes commenced. She had been given castor oil and quinine. A bougie had been introduced into the cervix and uterine cavity. The vagina had been packed with gauze. Following the above treatment, pains occurred at five minute intervals, but no uterine contractions were observed. The baby presented as a breech. Fetal heart sounds were loudest in the left upper quadrant, rate 160 per minute.

Her physical condition was poor. Temperature 98.6°F, pulse ninety, blood pressure 132/80. Erythrocytes 2,920,000, leukocytes 17,200. A catheterized specimen of urine showed a heavy trace of albumin, occasional hyaline and granular casts, and numerous pus cells.

This patient's rhythmical pains ceased after several hours. She changed very little in the next four days except that she became more exhausted, her temperature increased to 101°F, and her pulse increased to 110 per minute. Because of exhaustion and no progress, laparotomy under spinal anesthesia was resorted to December 29.

Through a midline incision a full term, living fetus was found free in the abdominal cavity. The uterus was in the anterior position, about the size and consistency of a three months pregnancy. The placenta was attached to the left ovary, and the broad ligament. The fetus was removed, and a supracervical hysterectomy and bilateral salpingectomy performed. This patient went into shock on the operating table, but improved when she was given 1100 c.c. of normal saline solution intravenously.

Following operation, her temperature fluctuated between 102° and 104°F. She was enormously distended, and died on the fifth day after operation of peritonitis and bronchopneumonia. The baby was normal, and lived.

This was reported as a ruptured ovarian pregnancy by Dr. Phillips, the pathologist.

CASE 6 E. J. (abdominal pregnancy, 34 weeks duration). In 1934¹ I reported a case of abdominal pregnancy which occurred in a negro, aged twenty. It was her first pregnancy, and of about thirty-four weeks duration. She complained of nausea, abdominal pain, and constipation during the entire pregnancy. For four weeks previous to

hospitalization, the abdominal pain had been more severe and associated with tenderness over the entire abdomen.

Physical examination showed an undernourished small woman whose blood pressure was 124/68, pulse one hundred, temperature 98.6°F. The fetus presented as a transverse. It was entirely above the level of the umbilicus, and easily palpated. The fetal heart sounds were loudest in the right upper quadrant. Palpation of the patient's abdomen and manipulation of the fetus failed to cause uterine contractions. The vaginal examination revealed a soft cervix in the normal position, with the canal closed. The uterus and pelvic structures could not be outlined.

Laboratory findings were erythrocytes 2,550,000, hemoglobin forty-five per cent, leukocytes 6,850. Wasserman reaction positive.

Under gas anesthesia, the abdomen was opened through a right para median incision. The fetus was free in the abdominal cavity and no definite sac was seen. The baby was removed. The placenta was attached to several coils of intestines, the uterus, both broad ligaments, and the anterior abdominal wall. It was left in situ, and the cord tied short. The abdomen was closed without drainage. The next day the patient was given a transfusion of 500 c.c. of whole blood.

After the second day this woman's temperature remained below 99°F. She had no distention, and voided spontaneously. The abdominal incision healed by primary union. The patient's urine was positive for pregnancy according to the Friedman test for thirty-five days after operation.

In February 1935, I delivered this woman by cesarean section of a second pregnancy, which was intrauterine. Careful inspection of the peritoneal cavity showed that the placenta, which had been left in the abdomen at the first operation, had been completely absorbed. The omentum was adherent to the lower angle of the abdominal incision and to the uterus at the site of the insertion of the right tube. No other adhesions were seen. The mother had a normal convalescence, and both babies are living and well.

CASE 7 E. J. (abdominal pregnancy), negro, aged twenty-three, married one year, gravida two, para one, was admitted to St. Philip Hospital August 2, 1935, because of pregnancy of forty-four weeks duration, dead fetus and several unsuccessful attempts to deliver the baby.

Her past history was unimportant. Menses commenced at age of fourteen, regular every month, duration two days without pain. She

physician because of pregnancy of eleven months duration and several unsuccessful attempts to induce labor. She had felt better since fetal movement ceased six weeks before hospitalization.

Her abdomen was symmetrically enlarged to the size of an eight months pregnancy, but the pregnancy was low. No fetal heart sounds were heard and we were unable to recognize the fetus on palpation. Vaginal examination showed the cervix firm, and long, with the external os closed but lacerated from a recent injury. The cervix was continuous with a mass the size of an orange, located in the left side of the pelvis.

X-ray examination confirmed the presence of a fetus, and abdominal operation was performed. The treatment was the same as in Case 1, except that this pregnancy was in the right broad ligament. The packing was completely removed by the sixth day. Her temperature remained below 101°F. The abdominal sinus had closed twenty-one days after operation.

Recently this woman has missed three menstrual periods, and is again pregnant.

CASE 3 M I (intraligamentous pregnancy, thirteen months pregnant), negro, twenty-five years old, married, was admitted to the hospital July 31, 1934. One former pregnancy was normal, and resulted in a living child which weighed ten pounds at birth. When seen this time she complained only of an abdominal mass and stated she had been pregnant since June 1933, but had felt no fetal movements since March 1934, four months before she entered the hospital. She had menstruated regularly during April, May, June, and July.

Examination showed the lower abdomen was distended with a mass which extended up to the level of the umbilicus. No fetal heart sounds were heard and manipulation failed to stimulate any contractions. X-ray examination showed evidence of a dead fetus.

Vaginal examination showed the external os closed, cervix long, firm, pushed to the right, and posterior. We were unable to outline the uterus.

Extra-uterine pregnancy was suspected. Under spinal anesthesia, the abdomen was opened, through a right para median incision. The body of the uterus was normal in size, pushed to the right, and under the symphysis pubes. The pregnancy was confined in the left broad ligament. We delivered fetus, placenta, and membranes, and then found it necessary also to remove the uterus to control hemorrhage. The abdomen was closed without drainage. Her convalescence was uneventful, and she was

discharged in good condition fourteen days after operation.

CASE 4 L A (intraligamentous pregnancy), negro, thirty-six years old, married. She had two living children and one former pregnancy terminated as an early spontaneous complete abortion.

She entered the hospital in July 1935, because of fainting spells, cramp-like, low abdominal pain, and irregular vaginal bleeding. Friedman's test was positive for pregnancy, and operation was advised because it was thought to be an ectopic pregnancy. She left the hospital against advice, but returned three months later because of pressure and pain in the lower abdomen.

Examination showed the lower abdomen contained a tender mass, the upper border of which measured twenty cm above the symphysis pubes. Below the umbilicus, the abdomen was extremely tender and somewhat rigid. No fetal heart sounds were heard. X-ray examination showed evidence of a dead fetus. Vaginal examination showed the cervix firm, closed, anterior, and high under the symphysis. The external os was closed. A diagnosis of ectopic pregnancy was made.

This patient was given a transfusion of 500 c.c. of whole blood. Then she was given spinal anesthesia, and the abdomen opened through a right para median incision. The body of the uterus was in the anterior position. It was soft and enlarged to the size of a three months pregnancy. A very much distended right broad ligament contained the pregnancy. The ligament was opened, and a macerated fetus removed. The placenta was attached to the base of the broad ligament, and we were unable to remove it. The intraligamentous cavity was packed with gauze, and the abdomen closed as in Case 1. The packing was entirely removed on the third day after operation. This patient had no bladder symptoms, very little abdominal distention and her temperature remained below 101°F. The sinus drained for three weeks, but was completely healed when she was discharged four weeks after operation.

CASE 5 (Dr LaRoque's case) R B (abdominal pregnancy, forty weeks duration), negro, aged forty, married twenty-three years, gravida three, para one, was admitted to St. Philip Hospital December 25, 1930, because of term pregnancy and irregular labor pains for four days.

Her early history was unimportant. Menses commenced at fourteen years of age and periods had been regular every twenty-eight days except during pregnancies. Her first pregnancy and labor were

head was in the upper right quadrant. There was marked overlapping of the cranial bones, suggesting a dead fetus. Although this patient improved slightly after she was admitted to the hospital, it was thought wise to induce labor. She was given one ounce of castor oil and five grains of quinine, but showed no evidence of uterine contractions.

The next day an intern attempted to introduce a Voorhees bag No. 4 into the cervix. He stated the bag was introduced with considerable difficulty, because the cervix was long and thick, and the internal os admitted only one finger. There was considerable resistance when the bag was inflated. The presence of the bag failed to stimulate uterine contractions during the next twelve hours. An eight ounce weight was then attached to the bag, and several hours later, without any evidence of labor, the bag was removed.

The next day this patient was examined by the author. On abdominal palpation, the fetal head was high, and in close proximity to the diaphragm. The baby seemed entirely too high in the abdomen for an intra-uterine pregnancy, and we were unable to stimulate any contractions. On vaginal examination, the cervix was long and thick. One finger was introduced with ease through the internal os. The body of the uterus was enlarged to the size of a two months pregnancy, and pushed somewhat to the left and anterior. A sponge forceps was introduced into the uterine cavity encountered resistance four inches from the external os of the cervix. An attempt was made to outline the uterine cavity by injecting lipiodol. Although fifteen c.c. were used, it was difficult to prevent leakage of the lipiodol through the cervix, and the x-ray plate was unsatisfactory. A diagnosis of extra-uterine pregnancy was made.

This patient was transfused with 500 c.c. of whole blood. Under gas and ether anesthesia, the abdomen was opened through a right para median incision. On opening the abdominal cavity a somewhat thickened and very vascular omentum was seen immediately under the abdominal incision. The omental blood vessels were very large, and some were probably more than one-half cm. in diameter. Careful inspection showed a definite sac under the omentum, extending over to the left side of the abdomen and up under the diaphragm, but not adherent to it. Below, the sac extended to the inlet of the true pelvis, and it was adherent to both broad ligaments and the posterior surface of the uterus about three cm. below the Fallopian tubes. The fundus and anterior surface of the uterus appeared to be normal. The body of the uterus was

soft and approximately the size of a three months pregnancy. The left anterior surface of the sac was opened, and a macerated fetus which weighed seven pounds, eleven ounces, was removed. It was apparently normal before death. The sac contained no amniotic fluid, and there was no evidence of internal hemorrhage. Further examination showed that the maternal surface of the placenta was attached to the posterior surface of the omentum, to several coils of the intestines, and it extended downward to the pelvic inlet. It was evident that any attempt to remove the placenta would cause profuse hemorrhage, therefore it was left in situ. The cord was tied short with catgut, and the abdomen was closed without drainage.

Temperature was 100.4°F. the day before operation and following operation it remained below 100°F until the evening of the second day, when at one reading it was 103°F. During the next sixteen days her temperature varied between normal and 101°F. During this time she received three transfusions of whole blood. The erythrocyte count remained around 3,580,000, leukocyte count around 16,000, and hemoglobin about sixty per cent.

On March 31, eighteen days after operation, her temperature at one reading was 103°. During the next seventeen days it varied between 100° and 103°F. Her abdomen was very much distended—but never rigid—and she had no evidence of intestinal obstruction. Her appetite remained good, and she had a daily bowel movement. On April 17, thirty-five days after operation, this patient had two very copious liquid stools, and her temperature dropped to normal. The abdominal distention, which had persisted since operation, decreased markedly. The patient stated she felt much better. Her pulse rate dropped from one hundred to ninety, and she improved rapidly.

On April 17 the leukocyte count was 6,900, but the erythrocyte count and the hemoglobin estimations remained unchanged. Her urine was tested by the Friedman test at frequent intervals, and it remained positive for pregnancy until April 6, twenty-four days after operation, and at least thirty-five days after the death of the fetus.

The abdominal incision healed by primary union. On vaginal examination, April 20, thirty-eight days after operation, the cervix was closed, body of the uterus small and directed anteriorly, and to the left. The pelvis was negative except for tenderness. She has continued to improve.

The diagnosis and treatment of these

had one former pregnancy which was normal, and had terminated in 1933 as a normal delivery. She remembered having a severe pain in the lower left abdomen about two months after her last menstrual period, but she denied having had any feeling of faintness. Except for nausea in the first three months, her pregnancy had been uneventful, until fetal movements ceased three weeks before hospitalization.

This woman stated she had been given castor oil and quinine to induce labor, and her physician told her he ruptured her membranes.

Her physical condition was poor. The blood pressure was 100/70, temperature 102°F, pulse 120 and weak. Erythrocytes 3,420,000, leukocytes 7,700, hemoglobin fifty-four per cent. Her abdomen was enlarged to the size of a term pregnancy, tender and rather tense. We were unable to outline the fetus, and abdominal manipulation failed to cause any noticeable uterine contractions. Vaginal examination showed the cervix soft, thick, long, and in about the normal position. The os was closed. The body of the uterus was to the left of the midline, soft and enlarged to the size of a three months pregnancy. We were unable to trace any connection between the cervix or body of the uterus and the abdominal mass.

X-ray examination showed a fetal skeletal outline with overlapping of the cranial bones. A diagnosis of abdominal pregnancy was made. Under spinal anesthesia, the abdomen was opened through a right paramedian incision, and a macerated hydrocephalic baby, weighing nine pounds and twelve ounces, was removed.

The anterior abdominal wall was thin but the peritoneum was adherent to a sac, the wall of which was one-half cm thick. This sac was adherent to the peritoneum of the anterior abdominal wall, to both broad ligaments, and the posterior surface of the liver. It contained the fetus, and 1000 c.c. of dark, thick, bloody fluid. After removing the fetus, the lower part of the sac was packed with gauze to control oozing, and the upper part of the incision closed without attempting to remove the placenta or membranes. Very little blood was lost during the operation, but the patient's blood pressure dropped to 80/50. She was given 1000 c.c. of a ten per cent glucose solution intravenously, but failed to improve after operation. She was typed for blood transfusion. Three members of her family were suitable for donors, but refused to give their blood. She died six hours after operation.

A partial autopsy was done and the placenta was found attached to the upper an-

terior abdominal wall and to the liver. The sac was also attached on its posterior surface to several coils of the intestines. There was no evidence of hemorrhage. The liver appeared to be largely replaced by the placenta and the damage to this organ probably caused the patient's death.

CASE 8 E W (abdominal pregnancy, forty-two weeks duration), negro, thirty-two years old, married seven years, was admitted to St. Philip Hospital Feb 26, 1936, because of term pregnancy, hypertension, blood pressure 160/110, edema, and albuminuria.

Her early history was unimportant. Her menses commenced at fourteen, were regular every twenty-eight days, and lasted three to four days. Two former pregnancies were normal and both children lived.

When admitted to the hospital she was about forty weeks pregnant. Following the birth of her last child in March 1935, she felt fairly well, and menstruated regularly in April and May. She had no evidence of menses and no vaginal bleeding after May. She felt quite ill during June. Her digestion was poor and she had considerable abdominal pain. Strong purgatives taken orally and mustard plasters applied over the abdomen failed to relieve the patient of her "misery."

In November 1935, five months after her last menstrual period, she noticed a mass in the right side of her abdomen, at the level of the umbilicus, which has persisted, and was not relieved by "mustard plasters."

On February 25, 1936, the night before admission to the hospital, she had severe pain in the left lower quadrant of the abdomen. When examined in the emergency room, she had headache, visual disturbances, and pain in the lower left abdomen. Her temperature was 102°F, pulse 110, respiration 28, blood pressure 160/110. Fetal heart sounds were not heard after admission to the hospital. Examination of the eye grounds showed advanced albuminuric retinitis. An abdominal mass was noted, which was thought to be the fundus of the uterus and measured thirty cm. above the symphysis pubes.

A catheterized specimen of urine contained many casts and four plus albumin. The phenolsulphonphthalein test was done and only fifteen per cent of the dye was eliminated in two hours. Blood examination was erythrocytes 3,840,000, leukocytes 9,600, hemoglobin sixty-eight per cent. Wassermann reaction was positive.

X-ray examination showed that the patient was pregnant. The baby presented as a breech, left sacroposterior. The fetal

The persistence of positive Freidman test for twenty-one and thirty-five days is a most interesting observation, as well as the absence of lactation in those cases where the placenta is left in situ

DR ALFRED C BECK, *Brooklyn*—Dr Ware was very fortunate in having treated personally seven cases of advanced, extra-uterine pregnancy. This condition is so rare that most men seldom see more than one or two cases in a lifetime. His experience, accordingly, is unique.

The loss of only one mother out of seven, a mortality of slightly under fifteen per cent, likewise is worthy of the highest commendation.

Seven of the eight cases reported showed no early evidence of tubal pregnancy. This freedom from early symptoms was not as common in the large series which I collected from the literature in 1919. I wonder if the difference may be accounted for by the difference in the type and mentality of the patients. All of Dr Ware's cases occurred in negro women who might be expected to complain less and, as a result, might very well forget early symptoms.

In case 4, the early symptoms were very definite and included vaginal bleeding. I wish to draw your attention to this fact because many men consider the vaginal bleeding in an ectopic indicative of fetal death. In this particular case, vaginal bleeding occurred and the fetus continued to live. Similarly, vaginal bleeding coincident with continued life of the fetus was observed in about one-third of the cases which I collected.

While the x-ray was helpful in the diagnosis of most of the cases reported by Dr Ware, apparently some difficulty was encountered in diagnosing two of them, since a bougie was introduced into the uterus of one and a bag was inserted in another. I recall that this was a rather common error in many of the cases that I collected. From my study I also concluded that absence of contractions was a valuable diagnostic aid.

Dr Ware did not mention the percussion findings in his cases. Because a loop of intestine may often be found in front of the gestation sac in an abdominal pregnancy, the finding of a tympanic note near the midline, in the region which ordinarily is occupied by the full term uterus, may be helpful in those cases which have not had a previous laparotomy.

As a result of the study of two hundred and sixty-two cases collected from the literature and our own experience up to 1919 I emphasize the following points in the treatment of this condition:

- 1 After opening the abdomen, all manipulations, including the extraction of the child, should be made very carefully, in order that partial separation of the placenta might be avoided.

- 2 Before deciding upon the method of handling the placenta, a careful exploration should be made to determine the proper method of procedure.

- 3 The placenta should be removed only in those cases in which its blood supply is accessible.

- 4 Before any attempt to remove the placenta is made, the vessels which supply the placental site should be ligated.

- 5 Whenever preliminary control of the circulation in the placental site is impossible, the placenta should be left in the abdomen.

- 6 The abdomen should then be closed without drainage except in the presence of hemorrhage and infection.

- 7 A placenta so retained will ultimately be absorbed.

- 8 Suturing of the sac to the abdominal wound and packing of its cavity with gauze should be limited to those cases in which bleeding necessitates the use of a tampon, or the presence of infection requires drainage.

In Dr Ware's cases, all of these procedures were used and I was glad to learn that the two mothers, in whom the placenta was left without drainage, recovered uneventfully. Since my original paper was written, two of my associates have had full term, living, abdominal pregnancies and, in both of these, the placenta was left within the abdomen and the wound was closed without drainage. Both of these mothers survived and, in one instance, when the abdomen was subsequently opened, as in one of Dr Ware's cases, no trace of the placenta could be found. As the good results of this type of treatment accumulate, I wonder if we should not be less anxious to remove the placenta. Treatment then would be very simple and would consist only in the removal of the child and the use of every effort to avoid partial separation of the placenta and hemorrhage from this source. Had such a routine been followed by Dr LaRoque in case 5, possibly the patient might have survived. It likewise might have been advisable in case 7, in which instance the patient was in bad condition at the time of operation, and died of shock within a few hours after its completion. I wonder why Dr Ware did not consider simply the removal of the child and closure of the abdomen without drainage, in this particular case.

I wish to thank Dr Ware for bringing these cases to our attention and congratulate him upon his unique experience and the excellence of his results.

cases has impressed us with the importance of managing each according to its indications

I am much indebted to Dr Alfred C Beck, of Brooklyn, N Y for the information obtained from his paper, "Treatment of Extra-Uterine Pregnancy after the Fifth Month"² My decision to leave the placenta in two cases, and close the abdomen without drainage was influenced by his experimental work and suggested treatment

Any one interested in late extra-uterine pregnancy will find a complete bibliography on "Full Term Intra-Abdominal Pregnancy" in a most comprehensive paper published by Drs Hellman and Simons last year³

Summary and Conclusions

The absence of any history suggestive of early tubal rupture in seven of the patients is important

The absence of any particular discomfort or pain until the fortieth week in three of the broad ligament pregnancies is significant

The patients with abdominal pregnancies all complained of vague abdominal pain, tenderness, indigestion, and constipation

Rhythmical uterine contractions were seen and palpated in one patient, and probably occurred in two others

Manipulation of the fetus failed to cause any rhythmical contractions in any of our patients

In abdominal pregnancy the fetus may either be palpated easily through the abdominal wall as in one of the cases reported, or difficult to palpate as in two other cases

The uterus was enlarged to the size of

a ten weeks pregnancy in seven

The cervix was closed, long, thick, and firm in seven of our cases

The fetus usually assumes an abnormal position

X-ray examination is a valuable aid in diagnosing extra-uterine pregnancy

In two patients with abdominal pregnancies, no attempt was made to remove the placenta, and the abdomen was closed without drainage The urine from these two patients gave positive Friedman tests for twenty-one and thirty-five days after operation

A moderate degree of anemia was noted in all cases, but the blood picture was of no particular diagnostic value

Complete absorption of the placenta from the peritoneal cavity of one patient was proven when her next pregnancy was terminated by cesarean section

Two patients in whom the placentas were left showed no evidence of lactation This suggests an inhibitory action of the placental hormones on the breasts

Extra-uterine pregnancy was diagnosed in seven of the cases without utero-salpingography This procedure is usually unnecessary

Of the eight cases reported, two died, a maternal mortality of twenty-five per cent. Seven of these patients were operated upon by the author, and among these there was one death, a maternal mortality of 14.28 per cent

Discussion

DR ALFRED M HELLMAN, *New York City*—The very fact that one institution had eight cases in five years proves the importance of this condition, and should make us grateful to Dr Ware for bringing it to our attention in such great detail and in so masterful a fashion

I reported one case in the literature—in this case the woman and baby both lived I had no trouble with the placenta as it was easily stripped from the posterior surface of the uterus, and where firmly

attached was removed with the left tube and ovary

The diagnosis should be made more often than is now the case

The diagnosis having been made operation is inevitable, and the problem then becomes, how shall the placenta be treated? If easily removable as in my case, of course, removal is desirable, if over firmly adherent, especially to intestines, it seems safest to leave it in situ, and when it becomes absorbed you feel how grand is nature

The persistence of positive Freidman test for twenty-one and thirty-five days is a most interesting observation, as well as the absence of lactation in those cases where the placenta is left in situ

I wish to thank Dr Ware for bringing these cases to our attention and congratulate him upon his unique experience and the excellence of his results

DR WARE (closing) I appreciate the discussion of my paper

All of the cases reported were referred to the hospital after examination and considerable manipulation. The type of pregnancy was not diagnosed correctly in any of these cases, before we examined the patients. The previously mentioned internal manipulation which I consider usually unnecessary, was done before these women were examined by us.

In our cases the pregnancies were anterior to the intestines, and consequently the value of percussion was limited.

I wish to stress the importance of a careful history, and physical examination. Abdominal palpation is particularly important.

The absence of any uterine contractions when the fetus is palpated abdominally and the absence of any contractile sac around the fetus suggests an extra-uterine pregnancy.

In our cases the cervix was long, thick, and more firm than in late intrauterine pregnancy.

Case 5 might have lived if no attempt had been made to remove the placenta.

Gentleness in examining these patients and at the time of operation will certainly reduce trauma and hemorrhage.

The placenta should be left in situ in all cases of abdominal pregnancy where its removal may be difficult. If the placenta is left, the abdomen should be closed without drainage.

DOCTORS AND DANGEROUS DRIVERS

Should the doctor be contented with patching the automobile victims up after the wreck? Or should he notify the Registrar of Motor Vehicles if he finds a driver who, physically or mentally, is a menace on the highway? If, for instance, asks the *New England Journal of Medicine*, a physician sees in private practice or at a hospital clinic a patient who has had epileptic attacks, should he assume responsibility for notifying the Registrar? Patients having petit mal attacks are probably more of a danger to the moving traffic than those who have grand mal attacks. On the other hand, if a patient, under long observation and adequate treatment for epilepsy, no longer suffers from attacks, should his license be renewable?

The same line of argument is to be considered in relation to mental disease. Are there not patients who still have mental symptoms driving on our highways? If a patient, moreover, has been an inmate of a State hospital for the insane or a private institution, ought he to have his license

revoked permanently? Are there not patients who make such a good recovery that they could again be trusted to drive an automobile? In addition to patients with nervous and mental disease, there are, of course, the large group who have definite physical handicaps. Is a patient with only one eye or who has partial vision in each eye a menace as a driver of an automobile? There are many other physical handicaps, such as the loss of an arm or a leg, which need to be considered.

This is not a new problem and provisions are made by the office of the Registrar of Motor Vehicles to handle the situation if the facts in regard to the individual are known to him. There must, however, be many individuals who have defects unknown to the Registrar, who are driving on highways. Should the medical profession take any action in this matter? Many physicians who are also conscientious citizens would like authoritative advice in regard to what to do when the problem arises in their own practice.

More than 200 physicians assembled on Nov 21 at Sherry's to celebrate the retention of 275 physicians to cooperate with the Police Athletic League by examining the 35,000 minors enrolled with it to determine their physical fitness for the sports in which they wish to engage.

Dr N Thomas Saxl, medical director of the league, said the purpose was to discover and correct any defects which might have an adverse influence upon them. Children

found to need medical attention were referred either to their own physicians or to the proper clinic.

Others who spoke were Deputy Police Commissioner Byrnes MacDonald, president of the league, Dr Bernard Sachs, Dr Ira S Wile and Dr C Ward Crampton, chairman of the committee on preventive medicine of the New York County Medical Society, who presided over the gathering.

TREATMENT OF GENERAL PARALYSIS BY ULTRA HIGH-FREQUENCY HEATING

LELAND E HINSIE, M D and JOSEPH R BLALOCK, M D, *New York City*

The value of the treatment of neurosyphilis, especially general paralysis, by heat-producing agents is a well-established fact. Since the eminent contributions of Wagner-Jauregg, many attempts have been made to reproduce the clinical conditions observed in patients under malarial treatment. These efforts have included the use of bacterial and chemical agents, hot water baths, and electropyrrexia, more particularly diathermy and ultra high-frequency.

Our own studies, dating from 1923, have been carried out at the New York State Psychiatric Institute and Hospital, first (from 1923-1930) with malaria and thereafter (1930 to date) with an electrical apparatus. Through the cooperation of the General Electric Company, we have been able to carry out research work with an ultra high-frequency apparatus. The present communication comprises a resume of the clinical use of such an apparatus among patients with general paralysis.

The technical aspects of the apparatus need not be elaborated upon in this group. As regards the treatment technique

The patient lies in a celotex box, which is placed between two large condenser plates. In from sixty to ninety minutes the body temperature is raised from normal to 104 or 105°F. The current is then turned off and the patient is placed in a warm bed. He is wrapped in blankets and a few hot water bottles are placed about him. The heightened temperature is maintained around 105°F about seven hours, the blankets are then removed and in one or two hours the temperature returns to normal.

The plan of treatment was such that each patient received ten individual treatments, each on alternate days. Each patient received a total of about seventy hours elevation of temperature over 102°F. Thus the malarial character of the febrile course was simulated.

Between June 1930 and January 1936

we have had 146 patients under treatment. All were adult patients with acquired general paralysis. None had received previous fever or tryparsamide therapy.

The case material may be divided into three treatment groups.

First, *fever only* with no other treatment for at least six months, in most cases there was no subsequent treatment. There were ninety-one patients in this group.

The second group consisted of thirty patients who received the fever series and then a course of twelve or more injections of tryparsamide intravenously. Bismuth was given intramuscularly at the same time that tryparsamide was given.

A third group of twenty-five patients was given tryparsamide just prior to each of the fever treatments. This was done in order to determine the efficacy of treatment when tryparsamide and fever were administered simultaneously. A half dose (15 gms.) of tryparsamide was given before each fever treatment. There were two treatments per week in order to lessen the danger of injury to the optic pathways. Tryparsamide and bismuth were usually continued after the termination of the fever series.

The patients were reexamined at regular intervals following the cessation of treatment. The figures are revealed in Table I.

First for discussion are the results which followed fever therapy alone—the first group. Here we have the largest number of patients followed for the longest period of time. These percentages represent results from ultra high-frequency fever treatment alone.

These results compare very favorably with those obtained under malarial treatment alone.

It is felt that the results obtained by combined treatment, that is fever with tryparsamide given during and after the fever course, are about the same.

In addition to the investigation of the clinical status we have made a practice

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

of doing a complete blood and spinal fluid examination prior to the fever series, at the termination of the series, and at approximately three months intervals thereafter

These tests were blood Wassermann, spinal fluid Wassermann, cell count, globulin, protein, and colloidal gold curve. The material is reported in two groups. The first consists of those patients who received fever only. The second consists of the other two groups, those who received fever, some with tryparsamide concurrently, and tryparsamide subsequently.

TABLE I—CLINICAL RESULTS

<i>High Frequency Fever Only</i>					
	6 mo (91) %	1 yr (86) %	2 yr (83) %	3 yr (70) %	4 yr* (73) %
Remission	17	19	18	15	11

Figures in parentheses indicate number of patients.

It was hoped by these studies to throw some further light on the question of the correlation of laboratory and clinical findings. It has been generally accepted that there is a lack of correlation, and that with time all tests gradually become negative regardless of the clinical condition.

Rather than present more statistics the serological changes are being presented in schematic form. The studies covered three years only.

Cells These were reduced quite promptly to normal in three-fourths of the patients. They were maintained as negative in three-fourths of the patients getting fever only and in nine-tenths of the patients receiving combined treatment.

Globulin In this the improvement was slower, reaching the maximum improvement in two years. This amounted to a negativity percentage of under forty-five per cent with fever only, and over sixty per cent with fever and tryparsamide.

As regards the spinal fluid protein, the reduction to normal with fever alone was prompt. When tryparsamide was subsequently given the per cent with normal findings increased up to over eighty per cent at two and three years while with fever only treated patients less than sixty per cent had become negative at these periods.

The changes in the remainder of the tests were much slower, and a much smaller number became negative. As regards the blood and spinal fluid Wassermann reactions and the colloidal gold reaction, about twice as many became negative with fever and tryparsamide as with fever treatment alone (at the one and two year periods).

At the two and three year periods, two-fifths of the blood and spinal Wassermann reactions were negative and two-thirds of the colloidal gold curves were "flat" or negative.

We have, therefore, as a result of these comparisons an indication that the blood and spinal fluid respond far more favorably in all the usual tests when tryparsamide is given in combination with or after ultra high-frequency fever than when this form of fever is given alone.

Study of other aspects such as per cent of negativity in the remissions and unimproved patients has not yet been completed.

It seems important to point out that favorable results were obtained with fever alone. The remission and improved rate was comparable with that obtained by us with malaria.

The patients tolerated the fever series well. An average of five pounds was lost during the course and several sustained no loss but a gain in weight. Only one death occurred which could be attributed to the fever itself.

With our particular ultra high-frequency electrical apparatus, about fifteen per cent received burns, usually blisters. In about 1500 individual treatments there were about six third degree burns.

Summary

We have presented the results obtained with ultra high-frequency since 1930 in 146 patients with general paralysis. The work has been done in a controlled and planned manner. We have shown the results of treatment of general paralysis from two points of view—with fever alone and fever in certain combinations with tryparsamide.

Conclusions

1 With fever treatment alone both the clinical course and the serological pictures are favorably influenced.

2 The use of tryparsamide following fever brings about the most favorable results.

3 There seems to be no advantage in giving tryparsamide just before each fever treatment.

Discussion

DR WALTER M. SIMPSON, *Dayton, O*—Doctors Hinsie and Blalock are deserving of praise for the exceptionally accurate manner in which they have utilized control measures to determine the relative efficacy of artificial fever therapy alone as compared with artificial fever combined with chemotherapy in the management of general paralysis. These studies coincide with our own observations that the combination of fever therapy plus chemotherapy is productive of a distinctly higher proportion of favorable results than the use of either pyretotherapy or chemotherapy alone.

At the Kettering Institute for Medical Research, Miami Valley Hospital, Dayton, we have subjected 431 patients to 3204 artificial fever treatments (approximately 17,000 hours of sustained fever) during the past five years. With the exception of occasional mild skin burns which occurred particularly at the beginning of this undertaking, no person has been injured by the treatments. During the first half of this study we utilized an air-conditioned modification of the ultra high-frequency apparatus used by Hinsie and Blalock. We have since devised apparatus (Kettering hypertherm) in which fever is induced and maintained by simple and controlled methods of air-conditioning; high-frequency electric currents are not employed. Deep tissue temperature studies made with thermocouples reveal no essential difference in the deep heating effect when fever is produced by either high-frequency currents or by conditioned air alone.

We have subjected twenty-seven patients with general paralysis to a course of fifty hours of fever therapy plus thirty injections of chemotherapy (bismuth arspenamine sulphate or neoarsphenamine and bismuth). We have felt that it was advantageous to inject the antisyphilitic drug just before the fever treatment is commenced on the basis that the general vasodilatation and increased velocity of blood flow during fever would permit greater diffusion of the chemi-

cal substances. It is ordinarily our practice to subject such patients to ten sessions of artificial fever therapy, each of five to six hours' duration at 105–106°F, at weekly intervals for ten weeks. Following the course of combined pyretotherapy, twenty injections of the antisyphilitic chemical agent are given, at weekly intervals. Twenty-one (77 per cent) of the patients with general paralysis have experienced complete clinical remission, three additional patients have been restored to a working status. Two patients were accorded fifty per cent clinical improvement, one demented patient obtained no improvement. Clinical relapse has not resulted in any case in which remission occurred. Eight of these patients were committed to a local hospital for the mentally diseased, and were brought to the Miami Valley Hospital for treatment. Sixteen of the twenty-seven patients had received presumably adequate chemotherapy, two had relapsed after receiving malaria therapy, and nine had received no treatment.

The fact that similar results have been obtained following the employment of a wide variety of fever-producing agents (malaria, rat-bite fever, relapsing fever, typhoid vaccine and other foreign protein substances, hot baths, hot air, electric blankets, and high-frequency electric currents) provides strong evidence that the common denominator of all of these methods—simple fever production—is the important, if not the only, factor in the production of favorable results. Despite the brilliant results which have been achieved with therapeutic fever following inoculations with malaria, rat-bite fever, and relapsing fever, the fact remains that the engrafted infection is capable of producing great damage, even death may be difficult to control, and is inconstant in its fever-producing properties. The advent of simpler and safer physical modalities has made it possible to treat patients much more uniformly, under controlled conditions, at any desired fever level. The type of apparatus employed is a secondary con-

sideration. Much more important is the adequate training of physicians and nurses who are charged with this work. In the hands of unskilled or unscrupulous persons, the possibilities for harm are great. If candidates for artificial fever therapy are subjected to a thorough diagnostic survey, with particular emphasis upon cardiac, vascular, and renal functions, the possibilities for disaster are greatly minimized. We prefer to regard artificial fever therapy as comparable in many respects to a major surgical operation, particularly as regards the necessity for the careful diagnostic survey to determine eligibility, and the constant attention to the patient by the physician and the nurse-technician during the long treatment.

Artificial fever therapy by physical means is not a simple undertaking. History is repeating itself in the attempts of certain manufacturers to exploit the field by utilizing modern high-pressure sales methods. Some of the apparatus now available through commercial sources is inadequate and dangerous and is sold to any physician without thought of adequate training of the supervising physician and his technical assistants. Artificial fever therapy cannot be entrusted entirely to the technician. It is our firm belief that artificial fever therapy by physical means should be restricted to institutions, in which the physician and nurse personnel has received adequate preliminary training. The production of effectual artificial fever is not adaptable to ordinary office practice. Unless these precautions are exercised this important ad-

venture in therapeutics is almost certainly doomed to a period of discredit, not unlike that which followed the introduction of Roentgen rays. In the hands of skilled and devoted workers, this form of therapy seems destined to occupy an increasingly important place in the therapeutics of several diseases which have been refractory to other therapeutic agencies.

DR WILLIAM BIERMAN, *New York City*—Drs Hinsie and Blalock have made a critical study of the results secured in the treatment of general paralysis by means of physically produced hyperthermia combined with the application of trypanamide. They have called attention to what appears at the moment to be the most effective method of treating syphilis of the central nervous system.

While their results have been obtained by means of the ultra high-frequency current and by subsequent heat insulation, the exact physical technic for the production of temperature elevation appears to make very little difference. The degree of temperature elevation and the time during which it is permitted to endure are the important physical factors.

In our more limited experience in the treatment of syphilis of the central nervous system, we have seen results comparable to those of Hinsie and Blalock. With increasing knowledge of the technic and its method of application, we may reasonably well expect that this method will gradually replace the more generally employed inoculation with malarial organisms.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting network.

Thursday, Dec 17, 1 30 P M—*Speaker* Dr M H Dawson, Asso Prof of Medi-

cine, College of Phys and Surg, Columbia Univ. *Subject* "What Can be done for Arthritis."

Thursday, Dec. 24, 1 30 P M—*Speaker* Dr Robert H Halsey, Prof of Clinical Medicine, Postgraduate Medical School and Hospital, Columbia Univ. *Subject* "How to be the Chauffeur of Your Heart."

The following broadcasts have been scheduled by the New York Tuberculosis and Health Assn under the auspices of the Medical Information Bureau of the New York Academy of Medicine from Station W2XR, Time, 6 00 P M.

Wednesday, Dec 16—*Speaker* Dr James

Ralph Scott, Chairman, New York Diabetes Assn. *Subject* "Diabetes."

Wednesday, Dec. 23—*Speaker* Dr Wendell J Stansby, Asst. Prof of Medicine, Cornell Univ Medical School. *Subject* "Public Health Aspects of Tuberculosis."

PRESENT STATUS OF SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM

W J MERLE SCOTT, M D, *Rochester*

*From the Department of Surgery, The University of Rochester
School of Medicine and Dentistry*

Although the gross anatomy of the sympathetic nervous system had been known for some centuries and the fundamental physiology of it for several decades, it was not until the time of the World War that any successful application of these facts had been made in clinical surgery. It is true that interruption of sympathetic tracts had been tried in the last decade of the eighteenth century but without success. During the World War, Leriche succeeded in relieving the causalgic pain in a number of instances following war injuries to primary nerve trunks or large arteries. Shortly after this, Jonnesco and others following him aroused the interest of the medical world by relieving pain in certain cases of angina pectoris after sympathetic interruption. However, the greatest stimulus to the developments in this new field of surgery came from the investigations of Royle and Hunter, from the controversy concerning certain phases of them, and particularly from their unexpected but accurate observations of the effects of sympathetic denervation on the function of the peripheral vessels and of the bowel. The twelve years which have followed the publication of their first results has been a fascinating story of exploration into the clinical possibilities of intervention on the sympathetic nervous system. While this phase of rapid discovery of new applications has probably not yet terminated, a sufficient interval has now elapsed so that a careful appraisal of results so far achieved will be of value to us both in guiding our clinical course and in establishing a basis for further investigative work in this field.

The chief disorders in the treatment of which sympathetic surgery has been carried out are assembled in Table I. What have been the results?

In the first place, the earliest surgical endeavors, namely by interruption of the cervical or thoracocervical sympathetic chain for epilepsy, glaucoma, and exophthalmic goiter, have been entirely abandoned as they resulted in no important relief of these conditions. These earliest operations were performed in the last decade of the eighteenth century and before the development of the more thorough methods that have been found necessary for a complete sympathetic denervation of the upper extremity. Undoubtedly in view of our present knowledge, the sympathetic denervation accomplished in these first operations in the head and neck regions was incomplete. Recent operations in certain selected cases of epilepsy have not resulted in any more striking permanent relief. I know of no series of glaucoma cases in which sympathectomies have been attempted in recent years. The operative relief in exophthalmic goiter by thyroidectomy has been so satisfactory and the operation itself simpler than cervicothoracic ganglionectomy so that the latter procedure has not been tried in recent times as a treatment for hyperthyroidism.

The relief of pain by periarterial sympathectomy in certain old injuries to arteries and nerves achieved by Leriche during the World War was the first successful application of sympathetic surgery, and the relief of certain types of pain remains today as one of the outstanding contributions in this new field of surgery. Thus the pain of angina pectoris, intractable forms of cystitis, essential dysmenorrhea, that accompanying the peculiar osteoporosis or paroxysmal ischemia following trauma, has in many instances been alleviated by the interruption of sympathetic pathways from the involved area. Where the pain is of sufficient se-

verity to warrant the procedure required, sympathetic surgery deserves trial in these types of painful disorders

In angina pectoris, relief by operations not too extensive for these handicapped

TABLE I

C N S	Epilepsy, migraine, multiple sclerosis
Eye	Retinitis pigmentosa, glaucoma, proptosis
Heart	Angina pectoris, paroxysmal tachycardia
Lungs	Asthma
G I	Paralytic ileus, megacolon
G U	Bladder pain, bladder paresis, reflex anuria, dysmenorrhea
General	Segmental sympathetic pain ('visceral') (including eroding aneurysm)
Endocrine	Exophthalmic goiter, diabetes, 'neurocirculatory asthenia'
Vascular	Hypertension, Raynaud's, vasomotor neurosis secondary to (a) functional nervous disorder (b) or organic nervous disorder (c) organic arterial disorder (d) trauma or fibrosis (including painful osteoporosis)
Sweat Glands	Hyperidrosis
Muscle	Spasticity

TABLE II—SYMPATHETIC INTERRUPTION UNSATISFACTORY

Epilepsy	}	Original uses Royle and Hunter
Glaucoma		
Exophthalmic goiter		
Muscular spasticity		

TABLE III—SYMPATHETIC INTERRUPTION OF PROVEN BENEFIT

	PAIN	PREFERABLE METHOD
Angina		Paravertebral alcohol injection
Vesical		Presacral neurectomy + 2 sacral ganglia
Dysmenorrhea		Presacral neurectomy
Painful osteoporosis		Try parietal, then gangli- onectomy
Vasomotor	MOTOR	Ganglionectomy for permanent
Paralytic bladder		Presacral neurectomy
Paralytic ileus		Novocain
Hirschsprung's disease		Try spinal anesthesia—gangli- onectomy

TABLE IV—SYMPATHETIC INTERRUPTION INSUFFICIENTLY TESTED

Retinitis pigmentosa	Reflex anuria
Migraine	Multiple sclerosis
Asthma	Hypertension

patients was achieved in only a proportion of the cases. Now nearly as satisfactory results have been attained in a much simpler manner by paravertebral alcohol injection which largely eliminates the operative mortality but which has the disadvantage of not being permanent. In addition, the paravertebral injection of alcohol has the further disadvantage of fre-

quently causing a painful neuritis of the nearby intercostal nerves which may be quite troublesome to the patient. In a severe angina, however, neither of these objections outweighs the advantages of the procedure. In addition to relief of pain, motor, inhibitory and secretory functions of the sympathetic nervous system have been suppressed by surgical interruption (Tables II, III, IV).

Let us briefly review by systems the more important of these efforts to influence various diseases. In the central nervous system, in addition to the failure of these methods in epilepsy, sympathetic denervation has also been carried out in migraine and in multiple sclerosis. In neither case has there been sufficient evidence on which to base an opinion of its value. In multiple sclerosis, a disease characterized symptomatically by marked phases of remission and exacerbation and pathologically by diffusely scattered areas of sclerosis, it seems illogical that overcoming a hypothetical spasm in the brain would result in a cure. However, the proof of the benefit of sympathetic denervation in any disease lies in the results accomplished rather than in any theoretical analysis. We should await later reports from those who believe that it may offer therapeutic help in this serious condition.

In the eye, in addition to the earlier trial in glaucoma, sympathectomy has been chiefly carried out for cases of retinitis pigmentosa, on the assumption that underlying the disintegration of the retina in this disease there might be a local spasm of the vessels. The early optimism has been changed to a deep pessimism by recent reports concerning the usefulness of sympathetic surgery in this disease. However, it does not seem to me that this form of therapy has been tried as yet in enough satisfactory cases to form a judgment of its value. We can definitely state that sympathectomy does not restore vision when retinitis pigmentosa has progressed to the stage of blindness. Also, it is probably true that when the degenerative process has advanced so that there is practically no peripheral field and only gunbarrel vision remaining, sympathetic surgery is of little avail. In the earlier cases before such extensive degeneration there may be more benefit

from sympathetic surgery. We have had two cases which showed definite improvement in visual acuity and a slight increase in the peripheral field. Kerr has reported several that seemed to be at least temporarily benefited by cervical sympathectomy. It is to these earlier cases of retinitis pigmentosa that sympathetic surgery in the future should be limited if it is used. A minor application for the eye is the purposeful production of enophthalmus by sympathetic denervation to assist plastic surgery in the control of prolapse of the eye due to an irremedial permanent paralysis of the facial nerve.

In the heart, the chief application has been in the attempted relief of angina which was discussed above. In a few instances, paroxysmal tachycardia has been sufficiently severe and persistent to warrant an attempt to control it by diminishing the sympathetic acceleration apparently with some degree of success. Patients with eroding aneurysm of the aorta have been freed from the severe pain associated with this condition by paravertebral alcohol injections.

In the lung the most important application of sympathetic surgery has been in attempting to relieve intractable asthma. The world literature on this subject was reviewed a few years ago by Phillips and Scott. There still have been too few cases operated upon to form any final judgment as to its value. Some very encouraging results have been reported however in extremely severe instances. Whether a more extensive removal of thoracic sympathetic nerves or the addition of vagus branches (posterior pulmonary plexus) is better, cannot be decided at present.

In the gastrointestinal tract, paralytic ileus not associated with peritonitis but of reflex origin seems to have as its basis an excessive sympathetic inhibition of motor activity in the small intestine. Based on this hypothesis, the temporary paralysis of the splanchnic nerves either by spinal anesthesia or by splanchnic anesthesia has been used with the intuition of peristalsis in many instances. Of course the effect is only transitory and sympathetic inhibition may shortly return in as severe a form as previously. But usually the breaking of the vicious circle with the relief of the distention of the

small intestine seems of definite benefit. The procedure is dangerous if there may be present an unrelieved organic obstruction, a weakening through gangrene of any part of the intestinal wall or a general toxicity. Thus it ought not to be used for example in the ileus associated with lobar pneumonia but it may be a life-saving measure in the early stages of certain forms of extremely severe reflex paralytic ileus. In Hirschsprung's disease of sufficient severity so that major surgery needs to be resorted to, sympathetic denervation has practically replaced the dangerous colectomies that formerly were resorted to in the extreme instances of this disease. Spinal anesthesia is of use as a preoperative test to make sure that the fundamental abnormality is an excessive sympathetic effect on the large bowel. Occasionally the elongated colonic loops may cause mechanical difficulty even after their muscular function has been improved by sympathectomy. Recently, in certain moderately severe cases, spinal anesthesia alone without further sympathetic intervention has seemed to be sufficient to turn the balance toward a more normal bowel function.

In the genitourinary tract, several applications of sympathetic surgery have proved beneficial. In paresis of the bladder where some sacral autonomic function still remains, the unpaired sympathetic innervation coming down outside the spine from higher levels of the cord may produce excessive inhibition. This is found in certain instances of the tabetic bladder and in some lower spinal injuries which do not completely destroy the sacral autonomic centers. By abolishing the sympathetic innervation of the bladder, marked improvement in the function of this organ has been achieved. Also in certain forms of intrinsic bladder pain, particularly associated with tuberculous cystitis and interstitial cystitis (Hunner's ulcer), gratifying results have also been achieved by sympathetic denervation of the bladder. In tuberculous cystitis, if only one kidney is involved, frequently relief will follow its removal but where both kidneys are simultaneously involved, this method is not advisable. Dr Schroeder and I found that for relief of the severe pain associated with deep inflammatory lesions of the bladder wall, di-

vision of the superior hypogastric plexus (presacral nerve) alone is insufficient to overcome this pain, and that it is practically eliminated if in addition to the resection of this plexus the first and second sacral sympathetic ganglia are also removed. Another form of pelvic pain which has proved amenable in many instances to sympathetic surgery is essential dysmenorrhea. When a severe dysmenorrhea is not associated with evident pelvic pathology and does not yield to conventional conservative and hormonal treatment, then presacral neurectomy is well worth trying. Usually if the psychoneurotic case is excluded from the series, this will result in very satisfactory relief. In reflex anuria, attempts to influence the condition by temporarily breaking the sympathetic reflex arc have been made, and it would seem that spinal anesthesia is worthy of a trial in severe forms of reflex anuria.

Attempts to influence certain endocrine functions through the sympathetic nervous system have been of interest. The first of these efforts we have already mentioned in connection with exophthalmic goiter. More recently, the attempt has been made to control certain recurrent forms of hyperthyroidism by sympathetic denervation of the adrenal cortex, the procedure being based on the hypothesis that adrenalin secretion either causes the fundamental metabolic disturbance or augments the effect of some other agent. Another interesting endeavor was interruption of the splanchnic innervation in juvenile diabetes mellitus in order to reduce the amount of insulin required in treatment. None of these have as yet yielded sufficiently definite results to consider that they are of established benefit.

Under certain conditions, the sweat glands function excessively either in local areas (usually with other signs of local sympathetic overactivity) or in larger regions, such as in both feet. This latter condition, hyperhidrosis, may result in sufficient discomfort to the patient or occasionally actually contribute to the maintenance of infection in the constantly damp skin and consequently warrant surgical intervention. Complete sympathetic denervation of the area permanently controls the excessive sweating.

Muscular spasticity associated with

upper motor neuron disorders has long been a serious clinical problem. It was in the effort to control such spastic tonus of the muscle that Royle and Hunter originally undertook their investigations. Although their first reports both in the experimental and clinical fields were quite optimistic in regard to the results, it is distinctly questionable today whether sympathetic denervation really influences the tonus of voluntary muscles in these conditions. However, the field of surgery of the sympathetic nervous system is enormously indebted to this problem as it was the by-products of this work which attracted attention to the therapeutically useful effects of sympathetic denervation on the vessels of the lower extremity and on the function of the large bowel.

The vascular system has been one of the major fields for the application of sympathetic surgery. Although since the time of Claude Bernard's classical experiment the vasomotor control of the vessels by the extrinsic sympathetic nerves had been known, the clinician did not visualize the possible benefit of interrupting this pathway until the accurate observation by Royle and Hunter of vasodilatation in the foot following lumbar ganglionectomy. That this unexpected result might be utilized in the treatment of certain vascular spastic conditions was immediately envisioned, and the test of time has verified the fact that arterial spasm in the lower extremities is satisfactorily controlled by lumbar ganglionectomy. Thus, for example, we have followed for ten years patients who had arterial spasm with thromboangitis obliterans. The vasoconstriction has been apparently permanently abolished, the foot remaining at approximately the vasodilatation level even though episodes of migratory phlebitis are not prevented by the denervation.

In the upper extremity, however, there has been an entirely different story, the inconsistencies of which are only now being resolved. At first, recurrent ischemic attacks in Raynaud's disease after thoraco-dorsal ganglionectomy were attributed to the fact that the sympathetic denervation of the extremity was incomplete. The distribution of vasomotor fibers from the thoracic ganglionated chain to the brachial plexus is very much more complicated than in the case of simi-

lar lumbar rami communicantes. However, after adequate technical procedures were developed for a complete denervation (proved by sweating tests) still typical ischemic attacks could occur in the hand. This fact kindled a lively controversy between those who believed Raynaud's disease to be merely a vasomotor neurosis and Sir Thomas Lewis' school who felt that there was a primary local fault. Recently, this matter has in my estimation been largely cleared up by establishing a humeral mechanism for causing such attacks. Since Elliott's investigation in 1905, physiologists have known that the degeneration of the postganglionic sympathetic fibers may produce hypersensitivity in that organ to circulating adrenalin. The Boston group have proved that such a hypersensitivity to very low amounts of circulating adrenalin exists in the denervated extremity of patients with Raynaud's disease and have actually induced typical ischemic attacks in such under conditions which cause an outpouring of adrenalin. Such hypersensitivity to circulating adrenalin does not result if the interruption of the sympathetic pathway is preganglionic, i.e. if the sympathetic end organs are still in direct communication with their ganglion cells. Based on these known physiological and clinical facts, they are advising preganglionic interruption and have devised an operative method for effectively accomplishing this. In true Raynaud's disease, we do not as yet know the fundamental cause of the excessive vasoconstriction. In addition to this idiopathic type of vasoconstrictor spasm there is a very interesting group of vasomotor neuroses definitely secondary to other conditions. Thus functional nervous disorders, such as hysteria, may be accompanied by a distinct local vasoconstriction in the affected area. Organic nervous diseases, particularly those associated with fibrosis whether of central or peripheral origin very often appear to produce an irritation of vasoconstrictor cells or tracts. Organic arterial disease, where an inflammatory or irritative lesion extends through the wall of the vessel to involve the adventitious coats and consequently probably to reach afferent sympathetic nerve fibers, often causes important vasomotor disturbances apparently of reflex

origin. The after effects of trauma or fibrosis probably by a similar involvement of the afferent sympathetic limb of a reflex arc are frequently associated with trophic changes, hypersensitivity to cold, local edema, ischemic attacks, etc., which quite definitely seem to be due to a vasomotor dysfunction. When the cause of such secondary vasomotor neuroses can be attacked, as the irritation of a cord or the brachial plexus being stretched between the anterior scalenus muscle and the projecting tip of a cervical rib, then this cause should be removed. This will usually relieve the vasoconstriction secondary to it. However, when the cause cannot be removed, as microscopic fibrosis which has followed the repair of the ravishes of trauma, and when the vasomotor disturbances threaten the viability or the function of the extremity, then some form of sympathectomy is advisable. We have not yet been able to subdivide this group accurately enough or to apply sufficiently precise tests to determine preoperatively the effect of each of the procedures at our command. So the choice of the procedure to be employed is still largely empirical. In general it can be stated that periarterial sympathectomy is limited in its usefulness to the group characterized chiefly by pain but if vasomotor functions are to be influenced more than temporarily, then this procedure is of no avail and we must resort to ganglionectomy, alcohol injection, or actual division of the peripheral nerves.

One of the most interesting chapters in the recent development of sympathetic surgery has been connected with the attempt through it to control essential and malignant hypertension. Dr. Wetherell has today discussed these developments and I will confine my remarks on this subject to the orientation of its present status in the field of sympathetic surgery. Today the attempt to control hypertension by any of the various sympathetic interventions proposed is distinctly in the phase of clinical research. The results have been sufficiently encouraging to warrant the undertaking of such operations when the patient's family understand and accept the experimental nature of the procedure. At present, however, we must definitely classify the attack in this field as insufficiently tested, not yet of defi-

nately established value. The majority of patients show distinct improvement in symptoms, some of them showing dramatic reductions in their blood pressure as well as improvement in their general condition which may be maintained for months. However, there is a discouraging tendency for a gradual climb back to the preoperative level of hypertension even among those patients where it is proved by pharmacological tests that the constricted arteries are still dilatable. We are gradually accumulating evidence strongly suggesting that the fundamental arterial spasm of essential and malignant hypertension is influenced by some vasospastic agency other than extrinsic sympathetic vasoconstriction and other than adrenalin secretion. Naturally we immediately think in this connection of the only well-known vasospastic endocrine hormone other than adrenalin, namely that from the posterior pituitary. Whether further investigation will bear out the suspicion that this agent is involved and whether, if it is, additional surgical or

chemical methods for its control can be elaborated, only the future can tell.

Summary

The sympathetic nervous system is one of the most recent additions to surgery. The work in this field to date has consisted largely in an exploration of the possibilities offered. However, in the last decade enough experience has accumulated to warrant certain preliminary deductions. Surgical interruption of the sympathetic nervous pathways can be classified in three groups on the basis of these results, (1) those of definite benefit, (2) those that have proved unsatisfactory, (3) those not yet sufficiently tested to establish their worth. Neither an uncritical enthusiasm nor a hopeless pessimism concerning the benefits of intervention on the sympathetic nervous system is warranted by the established facts. The results attained in the various systems to date are reviewed.

STRONG MEMORIAL HOSPITAL

DOCTORS STUDYING POISON GAS

Many seem to think that another World War is looming on the horizon, and all hope that we shall not be drawn in. If we should be, how many physicians know what to do in case of poison gas attacks? The British doctors are realizing their ignorance on this subject, and are preparing to learn everything possible about it. A recent speaker, addressing a meeting of secretaries of the British Medical Association, as reported in the *A M A Journal*, said that as a result of long thought and much deliberation with various representative medical bodies, a scheme has been evolved.

Ten physicians had been selected and had attended or were actually attending the Civil Anti-Gas School in Gloucestershire. These ten would be centered in various places throughout the country closely connected with medical schools, because one of their duties would be to train medical students. They would also instruct the practicing physician. For this purpose the machinery of the British Medical Association had been freely offered and gratefully accepted.

The air raids precaution department intended to place some forty or fifty trained

units in various localities. Each unit would draw classes from an area of from 10 to 15 miles. Then the unit would be shifted to another locality and the procedure repeated. Nothing less than twelve hours' instruction was likely to be sufficient. Major Blackmore suggested six periods of two hours each, one hour of theoretical and one hour of practical instruction. Whether that instruction took place six days in succession or one day a week or a fortnight was a matter of local arrangement.

The government would provide the instructors and equipment free of charge. The maximum in a class should be sixty, but from the point of view of practical instruction from thirty to thirty-five was a better number. A series of handbooks on the subject had been published by the government, of which one was clinical and designed for the medical profession. Gas masks would be available during the course.

Mobile gas chambers, of which some thirty-five or forty were already scattered about the country, would be available for instruction. The response to the scheme had been overwhelming and it would be necessary to increase the number of medical instructors.

ENTRANCE OF IODIZED OIL INTO THE CIRCULATORY SYSTEM DURING UTEROGRAPHY

GEZA WEITZNER, M D , New York City

The first x-ray visualization of the uterine cavity was performed by Cary¹ in 1914. He injected a solution of collargol into the uterus for this purpose. Owing to the numerous and painful reactions, the use of collargol never became popular. Scores of other opaque solutions were recommended by different authors in substitution of collargol. Kennedy² in 1923 recommended the use of a twenty per cent sodium bromide solution. William and Reynolds³ in 1925 suggested the use of barium sulphate and bismuth. Almost every heavy metal in some combination was given a trial and was used as a contrast medium in hystero-graphy. Such combinations were sodium bromide, sodium iodide, bromides in oil, bromionized oil, thorium, etc. Yet all these means failed to popularize the use and value of salpingo-uterography. Heuser⁴ introduced iodized oil in 1928. The use of iodized oil for x-ray purposes was pioneered by Sicard and Forestier⁵ in 1921. They used it first for the roentgenological diagnosis in body cavities, especially the skull. They were also able to prove convincingly the harmlessness of this oil.

Heuser's method gave the uterography the proper stimulus. Within a short time his procedure was adopted and generally used. At the present time, utero-salpingography with iodized oil as contrast medium has a well-established place in gynecology, especially in the diagnosis of female sterility. Its limitations and contraindications are well-established. Severe accidents are rare and easily avoidable. Only minor sequelae have been noted and reported such as peritoneal irritations, exacerbations of dormant inflammatory processes in the pelvis, iodism due to the absorption of the iodine ingredient in the injected oil, and the entrance of the injected iodized oil into the circulatory system from the uterus.

It is the latter accident which may occur during salpingo-uterography that will be discussed.

Taking into consideration the uterine blood supply with its large venous plexus the possibility of such an accident is easily conceivable although its occurrence was rarely reported until recently. This fact may be explained in one of two ways: *first*, that the x-ray films registering this accident had not been properly interpreted, and *second*, in the majority of cases in which this accident occurred, no ill effects were noted. Judging from the frequency with which this accident was observed in the Sterility Clinic of the Harlem Hospital one may presume that the entrance of iodized oil into the circulatory system is a fairly frequent accident during utero-salpingography. As these accidents are not always harmless and in some very rare instances may even cause death to the patient and as they are avoidable, their proper description and interpretation is recommendable.

One such case was published by the author⁶ in 1935. Brief histories of three additional cases are given herewith.

CASE 1. W. M. J., colored, twenty-one years old, was admitted in August 1930. Her complaints were sterility and sexual frigidity. She was married four years. She had one induced abortion of three months gestation in 1925. Same paternity as in the present conjugation. Menstruation onset at the age of fourteen, regular every twenty-eight days, duration three to four days, not painful. Amount of blood scanty. No previous illness or operation.

Gynecological examination revealed normal external genitalia, vagina roomy. Uterus small, ante-flected, freely movable. Right ovary cystic, left ovary and tube normal.

Tubal insufflation in April 1931 revealed patent tubes at sixty mm hg pressure. Two months later the patient had an attack of acute salpingitis. Tubal insufflation in July 1931 with 200 mm hg pressure was unsuccessful. Another at-

Fig 1 Immediate picture. Left hydrosalpinx. Oil entering the circulatory system at the right tubal cornu

Fig 2 Twenty-four hours after Fig 1 Remnants of oil in the left tube.

Fig 3 Immediate picture. Normal uterine cavity. Left isthmic block. Right tube patent for a distance of a $\frac{1}{4}$ "

tack of salpingitis in January 1932 left the patient with a permanently palpable right pyosalpinx, two-six cm in diameter. In June 1932, eight cubic cm of iodized oil was injected into the uterus for uterographic purposes. The time of this procedure took place three days after the cessation of the last period. Moderate pressure was used.

Immediate picture (Fig 1) showed the cavity of the uterus well-filled, the right tube closed at its isthmic end. The left tube closed at the fimbriated end (hydrosalpinx). Besides these findings, at the right cornu not far from the tip of the inserted cannula a triangularly shaped area was noted where the oil made its entrance into the uterine circulatory system. The twenty-four-hour picture (Fig 2) showed remnants of the oil in the left hydrosalpinx, none in the free abdominal cavity and none on the site of the described triangular area. The patient had no unusual symptoms during or after the hystero-graphy.

CASE 2 S G, thirty-three years old, white. Came under observation in May 1931. Her chief complaint was sterility of seven years duration. She was married eleven years. She had had four induced abortions of six to eight weeks gestations. No full term child. Last curettage in 1924. She started to menstruate at the age of twelve. Menses every twenty-eight days, regular, lasting two to three days, not painful. Amount of blood scanty.

Gynecological examination revealed normal external genitalia, roomy vagina, ante-flected uterus, normal in size, moveable, adnexa negative.

Insufflation test in May 1931 at 200 mm hg pressure revealed tubal occlusion. A second insufflation test in June 1931 with 220 mm hg pressure and with atropin administration gave the same negative result. In September, fourteen days after the end of the last period, eight c.c. of iodized oil were injected into the uterus under moderate pressure. The immediate picture showed (Fig 3) a normal uterine cavity, left tube not visualized, the right tube patent only for a distance of a quarter of an inch at its uterine end. No oil in the peritoneal cavity. A second iodized oil injection was made on November 17 with ten c.c. of oil injected under increased pressure. (Last menstruation November 12-15). During the injection the patient complained of some abdominal pain but showed no other ill effects. This abdominal pain disappeared promptly upon relaxation of the pressure. The immediate x-ray pictures (Fig 4) revealed a large uterine cavity, both tubes segmentally filled with oil to their fimbriated

ends. Beside these findings the body of the uterus, especially the fundus showed the penetration of oil into the myometrium. The circulatory system in the right parametrium was filled with oil making the right vena ovarica also visible. The twenty-four-hour picture (Fig 5) showed remnants of oil in the tubes and in the uterine cavity but none in the circulatory system. Subsequently several insufflation tests have been made but no tubal patency was obtained.

CASE 3 G D, twenty-three years old, colored. Admitted in May 1935. Her chief complaints were sterility and occasional abdominal pain. She was married five years. Nulli gravida. Menstruation, onset at the age of fifteen. Regular every twenty-eight days. Duration four-five days, not painful. Amount scanty. She had an appendectomy in 1926. Gynecological examination revealed normal external genitalia, vagina roomy, cervix centrally located, cone-shaped, pin point external os. Uterus small, anteverted, moveable. Adnexa negative.

Two insufflation tests performed in May and June with 200 mm hg pressure revealed tubal occlusion.

On July 3, 1935, eight c.c. of iodized oil was injected under moderate pressure into the uterus. Date of last menstruation was June 27, 1935. The immediate picture (Fig 6) revealed normal uterine cavity with isthmic block of the tubes. The entire venous system of the uterus filled with oil, especially the left vena ovarica. The twenty-four-hour picture (Fig 7) revealed no oil in the pelvis. No ill effects were noted during and after this injection. On July 31 two days after cessation of the menstruation and twenty-eight days after the previous salpingography, ten c.c. of iodized oil were injected with the cannula of the same length and in the same position. The immediate picture (Fig 8) showed almost identical shadows as viewed on the previous occasion. Normal uterine cavity, isthmic block of the tubes, venous, circulatory system filled with oil, both venae ovaricae visible. Films taken five minutes after the injection of the oil showed similar pictures with the oil more advanced in the veins making the two venae ovaricae visible almost in their entire length. Several pictures were taken at ten minute intervals from the lungs but they were all negative and no trace of oil emboli could be detected. The twenty-four-hour picture revealed the complete disappearance of the oil from the pelvis. The patient did not have any ill effects on this occasion either.

Fig 4 Immediate picture. Large uterine cavity. Tubes segmentally filled, not patent. Oil in the body of the uterus. Left vena ovarica visible.

A third hystero-uterography was undertaken in November 1935. This time in the third week of the menstruation cycle. The cannula was shortened to prevent injury of the uterine mucosa. Two c.c. of oil was injected at four intervals and pictures taken in every phase. Until the sixth c.c., the injection required moderate pressure. In injecting the last two c.c. the pressure had to be increased considerably causing some abdominal discomfort to the patient. The two c.c. picture (Fig 9) showed an insufficient filling of the uterus with isthmic block of the tubes. In the four c.c. picture (Fig

Fig 5 Twenty-four hour picture. Remnants of oil in the tubes. None in the veins.

Fig 6 Immediate picture. Normal uterine cavity Isthmical block of the tubes Oil in the circulatory system Both venae ovaricae visible

Fig 7 Twenty-four hour picture. No oil visible in the pelvis

10) the uterine cavity was better filled but still incompletely with isthmic block of the tubes The six c.c picture (Fig 11) showed the entire cavity well-filled, and the oil entering the tubes to the fimbriated ends, but oil in the peritoneal cavity The eight c.c picture (Fig 12) showed the effects of the increased pressure, uterine cavity rounded out on the fundus, and the internal os dilated facilitating the filling of the cervical canal with oil No oil was visible in the circulatory system The twenty-four-hour picture (Fig 13) showed the pelvis free from any oil remnants

Twenty-one similar cases have been reported in the literature to date In these as in several other publications, references were made toward the existence of other cases

The first five cases were reported in 1929 by Pujol, Brull, Vanrell, and Riera⁷ All five cases have been young women complaining of sterility In each case moderate pressure was used The quantity of oil is not given One case had uterus septus, one had a uterine polyp, one case had metropathus hemorrhagica, and two cases had normal uteri In all cases, the tubes were found closed Except for some hemoptoe of short duration in one case, no ill effects have been noted As far as the cause is concerned, these authors ascribe the accident to (a) lesion of the uterine mucosa or (b) excessive pressure.

The next two cases were published by Witwer, Cushman, and Leucutia⁸ in 1930 They used only five c.c of oil with moderate pressure in each case, yet the oil entered the circulatory system In both cases, the injection was repeated ten days later

Fig 8 Immediate picture. Normal uterine cavity Isthmical block of the tubes Oil again filling the veins

Fig 9 Two c.c. oil injected Insufficient filling of the uterine cavity Tubes not visualized

and the oil again entered the circulatory system. These facts induced the authors to assume that an increased pathologic permeability of the receiving sinuses facilitated the entrance of the oil. They observed no ill effects either.

E. Gajzago's⁹ case stands unique with its result. The patient in this case died within nine hours after the injection of the oil. She was sixty years old, white, para six, complaining of a six weeks metrorrhagia. The gynecological examination revealed a fist-sized fibromatous uterus with cervical decubitus, and prolapsed vagina. To ascertain the exact location of the fibroma whether it was intramural or submucous, eight c.c. of oil was injected under eighty mm hg pressure with fluoroscopic visualization. The picture showed the presence of a submucous fibrom. Shortly after the injection the patient collapsed and became

Fig. 12 Eight c.c. oil injected. Uterine cavity rounded out at the fundus. Oil in the cervical canal. Tubes still closed at the fibrinated ends.

Fig. 10 Four c.c. oil injected. Uterine cavity still insufficiently filled. Oil entering tubes.

Fig. 12 Twenty-four-hour picture. Pelvis free from oil remnants.

Fig. 11 Six c.c. oil injected. Uterine cavity well-filled. Tubes filled with oil to the fibrinated end. No oil in the peritoneal cavity.

unconscious. Heart stimulants somewhat improved her condition for a few hours, but expired at the end of the ninth hour. The autopsy and the microscopic examination revealed the presence of oil emboli in the lungs, heart, kidneys, spleen, liver and in the capillary system of the hypophysis. The intrauterine fibrom was covered with dilated veins of which one showed the site of the injury caused by the inserted cannula. Gajzago advises that the amount of oil should be limited to three to five c.c. and the pressure to sixty-eighty mm hg.

Amos, Wong, Wu and Chien¹⁰ reported five cases in 1932. Their patients were all young Chinese women complaining of sterility. Three of them had infantile uterus. Two had normal genitalia organs. The hysterographies were made during the first

postmenstrual week. In all of their cases, obturated tubes were found. No ill effects were noted. They emphasized the harmlessness of the accident despite the fact that in their animal experiments they were able to kill one and one-half to two kilogram rabbits with an intravenous injection of one c.c. of oil

R. Solal¹² had one case in 1932. His patient was a nulli gravida with a small infantile uterus. She was injected on the fifth postmenstrual day. The pressure was measured and steadily maintained under 200 mm. hg. Bicornuate uterus with closed tubes was found. Four weeks later on the fourth postmenstrual day, the injection was repeated. The same pictures were obtained with the oil again entering the circulatory system. There were no sequelae.

D. Zacharin's¹³ case in 1933 had also an infantile uterus. The injection was performed on the seventh day after the cessation of the last menses. A small uterine cavity was visualized with patency of the right tube. The pictures which were taken ten minutes after the injection of the oil showed that the oil completely disappeared from the circulatory system of the pelvis. The patient had some cough during the procedure but no other noteworthy ill effects.

Portes and Beclere¹⁴ also in 1933, reported one case. Their patient was a young woman complaining of sterility. She had a previous gynecological operation during which a bilateral salpingectomy and unilateral corphoretomy were performed. These authors used 300 mm. hg. pressure under fluoroscopy. Their patient had moderate fever of one day duration, nothing unusual was noted thereafter.

Kilroe and Hellman¹⁵ reported their case in 1933. The pictures showed bilateral patency of the tubes. A repetition of the procedure ten days later gave the same results with the oil again visible in the circulatory system. They adhered to the theory that this was due to a pathological permeability of the circulatory system.

Coventry¹⁶ in 1934 had one case in which the tubes were also closed. His patient had chills, nausea, and rapid respiration of ten minutes duration but no other ill effects. Pictures taken ten minutes after the injection showed the oil disappeared from the pelvic circulatory system completely.

Meaker¹⁷ injected eleven c.c. of oil under 300 mm. hg. pressure. No ill effects were experienced in this case.

Torres¹⁸ had one case. A bicornuate uterus was injected. Normal uterine cavity was visualized, both tubes closed at their uterine ends. No ill effects noted.

P. Porcher¹⁹ in 1935 injected gradually $1\frac{1}{2}$ - $2\frac{1}{2}$ - $3\frac{1}{2}$ c.c. of oil into an infantile uterus. He took x-ray pictures in every phase. While at the beginning of the procedure, nothing unusual was noted, at the $3\frac{1}{2}$ c.c. phase he observed that the oil entered the uterine circulatory system. No ill effects were observed.

The author's case⁴ was a thirty-five year old nulli para who had a previous salpingectomy and appendectomy. Eight c.c. of oil were injected under moderate pressure on the third day after the cessation of the last period. Normal uterine cavity was visualized with patent right tube and oil in the venous system, making the venae ovaricae visible. No ill effects were noted. Several consecutive hystero-graphies were done on this patient, each time the procedure done in the third week of the menstrual cycle. Result: no oil entered the circulatory system.

Conclusions

In analyzing these twenty-four cases, it should be emphasized that except in one peculiar case the ill effects in all other instances have been of a negligible character, described as chills, fevers, coughs, and hemoptysis of short durations. It seems that something in the uterus acts as a strainer retarding the progress of the intravasated oil and disperses it to a degree sufficient to render the accident practically harmless. In Gajzago's case, a veritable intravenous injection of oil took place, hence the fatal outcome. The dispersing and straining action of the uterus plays a major role in safeguarding the patient from oil emboli.

Sicard and Forestier¹⁹ were able to inject into the human cubital vein four c.c. of iodized oil with safety, causing by this action only a slight cough to the patient. They were also able to follow the progress of the injected oil into the lungs, and the disappearance of the oil in the lungs within ten minutes.

Age, race, previous pregnancy, and tubal patency seem to play a minor part in producing this accident. Infantile and small uteri or fibromatous uteri are facilitating factors.

The diagnosis of the intravasation during hystero-graphy is made only by proper reading and interpretation of the immediate and delayed pictures. In the im-

mediate pictures besides the usual designs of the uterine cavity and tubes, sharply demarcated additional visualizations can be observed to which the ascending shadow of the *venae ovaricae* is very often added. Oil in the free peritoneal cavity had indefinite margins. In the delayed pictures, even if taken within fifteen minutes after the injection, there is complete disappearance of the oil from the circulatory system. This disappearance of the oil makes the diagnosis conclusive.

As far as the etiology is concerned, three explanations have been advanced by the different authors: (1) Excessive pressure. (2) Pathological permeability of the circulatory system. (3) Injuries to the uterine mucosa.

1 Excessive pressure as etiological factor could be discarded on the ground that cases with patent tubes have been intravasated, in addition almost every author emphasized the moderate and very often measured pressure which was used during the hystero-graphy.

2 Pathological permeability of the circulatory system is also a very improbable cause of this accident. The author in his experimental cases was able to avoid or repeat the accident *ad libitum*, by changing the time of the hystero-graphies. The oil escaped into the circulatory system when the injection was made immediately after cessation of the menstruation and vice-versa, the oil did not enter the circulatory system if the injection was placed on the third week of the menstruation cycle. If such a condition as pathological permeability exists, the oil should have entered the circulatory system each time the hystero-graphy was done.

3 Injuries to the uterine mucosa. Sampson²⁰ in 1918 and later Beclere²¹ were able to fill the uterine circulatory system with opaque solutions in operative and autopsy specimens via the uterine cavity whenever the intactness of the uterine mucosa was disrupted by physiological bleedings or by curettage. The postmenstrual and post-hemorrhagic uterine mucosa seem to have a greater vulnerability and the receiving venous sinuses of the submucosa an increased penetrability, and these conditions are the principal factors which facilitate the entrance of the injected iodized oil into the circulatory system of the uterus. Small and infantile uteri being shorter than normal, are easier to injure.

The time of the hystero-graphies in the clinic of the Harlem Hospital was routinely placed on the first week after cessation of the period with the idea that the injections should not interfere with the arrival of the new born ovum. The frequency with which the intravasation was observed with this routine coupled with the above described experiments caused the routine to be changed so that the hystero-graphy takes place during the third week of the menstrual cycle. Thus at least ten to fourteen days time is given to the uterine mucosa for its repair.

The quantity of the oil is limited to six-eight c.c. The length of the cannula adequately shortened to the length of the uterine cavity. Moderate pressure is used and interrupted pictures at two, four, six, and eight c.c. are taken. It is expected by this method that a better and more accurate diagnosis may be made of the existing pelvic conditions and the occurrence of the described accident will be practically eliminated.

Summary

1 The history of three cases with reproductions of the x-ray pictures are presented in which the injected oil entered the circulatory system of the uterus.

2 Twenty-one such cases have been reported previously in the literature.

3 Except in one case where exitus took place in all other cases, the sequelae have been of a negligible character.

4 The cause of the phenomenon presumably rests in the vulnerability of the uterine mucosa in the postmenstrual and posthemorrhagic stages and in the penetrability of the receiving sinuses.

5 Hystero-graphies should be placed on the tenth to fourteenth postmenstrual or posthemorrhagic day to avoid this accident.

6 The amount of oil should be limited from six to eight c.c.

7 Interrupted and delayed pictures taken one hour after the injection are of great value in making an accurate diagnosis.

SENSITIVITY TO EXTERNAL IRRITANTS IN INDUSTRY

LOUIS SCHWARTZ, M D , *New York City*

Senior Surgeon, U S Public Health Service, Washington, D C

Of prime importance in the prophylaxis and treatment of industrial dermatitis is knowledge of the factors which predispose workers to sensitivity to external irritants

The defense mechanism of the skin against external irritants consists of the cornified cells of the outermost layer and of the secretions of the glands of the skin. The cornified cells are insoluble in water and alcohol and will withstand the action of even fairly strong acids but are attacked by alkalis and sulphides. The perspiration acts as a diluent of irritants which are water soluble and the sebaceous secretions, consisting of cholesterol and liquid waxes, form a protective coating against water soluble irritants. The pigment of the skin also acts as a protective factor against certain skin irritants. The perspiration and the sebaceous matter may, however, under certain conditions act as aids to irritants on the skin.

The vulnerable portions of the skin are the openings of ducts and hair follicles through which certain chemical compounds, especially those which are fat soluble, may easily enter. Thinning or breaks in the cornified layer of the epithelium also act as portals of entry for external irritants.

All matters affecting the defense mechanism and the vulnerable portions of the skin play roles in sensitivity to external irritants. The first of these factors we will consider is race.

It is well-known in industry that the negro is less susceptible to the action of skin irritants than the white man. In such occupations as work on grinders and driers in dye factories, where there is exposure to irritating dust and irritant dyes, many industrial concerns will employ only negroes because by actual experience they have found them to be less sensitive

to skin irritation. Different types of skin even in the Caucasian Race differ in sensitivity to external irritants. Many factories will not employ those with thin, blond skins in occupations where they come in contact with potential skin irritants. Workers having greasy, oily, thick skins withstand the action of such fat solvents as soaps, turpentine, naphtha, benzol, trichlorethylene, and carbon tetrachloride better than those with dry skins. On the other hand, in occupations where oils, greases or waxes are apt to soil the clothing, as for instance, in oil refineries, machine shops, garages, etc., we have observed that those with much hair on the arms and legs and with excessive sebaceous secretion, are more likely to develop acne-like lesions and folliculitis.

In a certain glass factory, where an outbreak of folliculitis occurred among workers whose clothes became saturated with oil, it was noted that the most severe cases occurred among those workers with the most hair on the legs and arms and that the smooth-skinned ones escaped entirely.

In a study of skin hazards among workers with chlorinated naphthalenes and diphenyls, it was found that while all the workers who were exposed for a length of time developed comedones and acne-like lesions, the worst cases occurred among men with dark, swarthy, oily skins, who were in the acne age. The older men, especially those with fair skins, had very few or no pustules at all, but simply yellowish non-inflammatory comedones or cysts.

Various portions of the skin of the same individual differ in susceptibility to external irritants. We have found in our studies that the inner surface of the forearm and the upper arm where the

THE CAMERA IN MEDICAL PRACTICE

Many physicians are camera enthusiasts. Most photographic clubs number many doctors in their membership and the work exhibited by some is professional in its technic. However, few doctors think of utilizing photography in their daily work. There are many advantages in doing so, remarks the *Medical World*.

No description can equal in telling force the actual picture of a lesion. Case records become of far greater value when before and after photographs are attached for the doctor's own benefit and to show the patient in certain circumstances. Often a doctor likes to delve into his records for the preparation of a medical paper and such photographs can be used for the making of lantern slides thereby enhancing his reputation as an exact observer and causing him to be called upon to address medical groups. There is a certain amount of protection to the doctor in keeping good photographic records. They could be the means of winning a malpractice suit, and none of us is exempt from this contingency.

The equipment necessary for medical photography consists of a camera with a good and comparatively rapid lens, a steady tripod and a suitable lighting unit. There are many cameras on the market made especially for the purpose. One recently introduced is mounted in front of a reflector with the shutter and flash-light bulb synchronized, the latter working from a battery. Arms extend from the apparatus and are placed against the patient to regulate the distance

The resulting negative is of lantern-slide size. It is not essential to have a special, and probably expensive, camera for the purpose, however. A moderately priced camera, providing its lens is sufficiently rapid, will answer just as well. There must be sufficient light, of course. A single reflector with a 500-watt projection bulb or photoflood light will be found most convenient. The photoflash bulbs mentioned above are very handy but prove expensive when a great deal of work must be done. The best size of negative is the $3\frac{3}{4}'' \times 4\frac{1}{4}''$ since lantern slides can be made directly from it and because it is more economical than larger sizes. If larger pictures are wanted, enlargements can be made at moderate cost.

The best type of camera is the one that uses plates or film packs, since this permits the negative to be developed individually and gives greater latitude in time exposures. The kind of film used is an item of importance. Panchromatic film, being sensitive to reds, makes the finest medical pictures but is very sensitivity to red gives an added problem in development, for it must be loaded in the dark and then must be desensitized without the usual red light of the dark room before actual development is started. The doctor who does his own developing will not find this a great problem but if he sends his films out for developing he must be sure that his photographer understands that he is handling panchromatic film.

PEOPLE ARE HEALTHIER AND HAPPIER

When President Charles Gordon Heyd, of the A M A visited Rochester in November to address the doctors there, he assured the reporters that America is headed

for happiness. As they reported him "Why? It's simple. When people are healthy, they are happy—life is better. And people are growing healthier each year."

SENSITIVITY TO EXTERNAL IRRITANTS IN INDUSTRY

LOUIS SCHWARTZ, M.D., *New York City*
Senior Surgeon, U S Public Health Service, Washington, D C

Of prime importance in the prophylaxis and treatment of industrial dermatitis is knowledge of the factors which predispose workers to sensitivity to external irritants.

The defense mechanism of the skin against external irritants consists of the cornified cells of the outermost layer and of the secretions of the glands of the skin. The cornified cells are insoluble in water and alcohol and will withstand the action of even fairly strong acids but are attacked by alkalis and sulphides. The perspiration acts as a diluent of irritants which are water soluble and the sebaceous secretions, consisting of cholesterol and liquid waxes, form a protective coating against the skin also acts as a protective factor against certain skin irritants. The perspiration and the sebaceous matter may, however, under certain conditions act as aids to irritants on the skin.

The vulnerable portions of the skin are the openings of ducts and hair follicles through which certain chemical compounds, especially those which are fat soluble, may easily enter. Thinning or breaks in the cornified layer of the epithelium also act as portals of entry for external irritants.

All matters affecting the defense mechanism and the vulnerable portions of the skin play roles in sensitivity to external irritants. The first of these factors we will consider is race.

It is well-known in industry that the negro is less susceptible to the action of skin irritants than the white man. In such occupations as work on grinders and driers in dye factories, where there is exposure to irritating dust and irritant dyes, many industrial concerns will employ only negroes because by actual experience they have found them to be less sensitive

to skin irritation. Different types of skin even in the Caucasian Race differ in sensitivity to external irritants. Many factories will not employ those with thin blond skins in occupations where they come in contact with potential skin irritants. Workers having greasy, oily, thick skins withstand the action of such fat solvents as soaps, turpentine, naphtha, benzol, trichlorethylene, and carbon tetrachloride better than those with dry skins. On the other hand, in occupations where oils, greases or waxes are apt to soil the clothing, as for instance, in oil refineries, machine shops, garages, etc., we have observed that those with much hair on the arms and legs and with excessive sebaceous secretion, are more likely to develop acne-like lesions and folliculitis.

In a certain glass factory, where an outbreak of folliculitis occurred among workers whose clothes became saturated with oil, it was noted that the most severe cases occurred among those workers with the most hair on the legs and arms and that the smooth-skinned ones escaped entirely.

In a study of skin hazards among workers with chlorinated naphthalenes and diphenyls, it was found that while all the workers who were exposed for a length of time developed comedones and acne-like lesions, the worst cases occurred among men with dark, swarthy, oily skins, who were in the acne age. The older men, especially those with fair skins, had very few or no pustules at all, but simply yellowish non-inflammatory comedones or cysts.

Various portions of the skin of the same individual differ in susceptibility to external irritants. We have found in our studies that the inner surface of the forearm and the upper arm where the

THE CAMERA IN MEDICAL PRACTICE

Many physicians are camera enthusiasts. Most photographic clubs number many doctors in their membership and the work exhibited by some is professional in its technic. However, few doctors think of utilizing photography in their daily work. There are many advantages in doing so, remarks the *Medical World*.

No description can equal in telling force the actual picture of a lesion. Case records become of far greater value when before and after photographs are attached for the doctor's own benefit and to show the patient in certain circumstances. Often a doctor likes to delve into his records for the preparation of a medical paper and such photographs can be used for the making of lantern slides thereby enhancing his reputation as an exact observer and causing him to be called upon to address medical groups. There is a certain amount of protection to the doctor in keeping good photographic records. They could be the means of winning a malpractice suit, and none of us is exempt from this contingency.

The equipment necessary for medical photography consists of a camera with a good and comparatively rapid lens, a steady tripod and a suitable lighting unit. There are many cameras on the market made especially for the purpose. One recently introduced is mounted in front of a reflector with the shutter and flash-light bulb synchronized, the latter working from a battery. Arms extend from the apparatus and are placed against the patient to regulate the distance

The resulting negative is of lantern-slide size. It is not essential to have a special, and probably expensive, camera for the purpose, however. A moderately priced camera, providing its lens is sufficiently rapid, will answer just as well. There must be sufficient light, of course. A single reflector with a 500-watt projection bulb or photoflood light will be found most convenient. The photoflash bulbs mentioned above are very handy but prove expensive when a great deal of work must be done. The best size of negative is the $3\frac{1}{4}'' \times 4\frac{1}{4}''$ since lantern slides can be made directly from it and because it is more economical than larger sizes. If larger pictures are wanted, enlargements can be made at moderate cost.

The best type of camera is the one that uses plates or film packs, since this permits the negative to be developed individually and gives greater latitude in time exposures. The kind of film used is an item of importance. Panchromatic film, being sensitive to reds, makes the finest medical pictures but is very sensitive to red gives an added problem in development, for it must be loaded in the dark and then must be desensitized without the usual red light of the dark room before actual development is started. The doctor who does his own developing will not find this a great problem but if he sends his films out for developing he must be sure that his photographer understands that he is handling panchromatic film.

PEOPLE ARE HEALTHIER AND HAPPIER

When President Charles Gordon Heyd, of the A M A visited Rochester in November to address the doctors there, he assured the reporters that America is headed

for happiness. As they reported him "Why? It's simple. When people are healthy, they are happy—life is better. And people are growing healthier each year."

SENSITIVITY TO EXTERNAL IRRITANTS IN INDUSTRY

LOUIS SCHWARTZ, M D , *New York City*

Senior Surgeon, U S Public Health Service, Washington, D C

Of prime importance in the prophylaxis and treatment of industrial dermatitis is knowledge of the factors which predispose workers to sensitivity to external irritants

The defense mechanism of the skin against external irritants consists of the cornified cells of the outermost layer and of the secretions of the glands of the skin. The cornified cells are insoluble in water and alcohol and will withstand the action of even fairly strong acids but are attacked by alkalis and sulphides. The perspiration acts as a diluent of irritants which are water soluble and the sebaceous secretions, consisting of cholesterol and liquid waxes, form a protective coating against water soluble irritants. The pigment of the skin also acts as a protective factor against certain skin irritants. The perspiration and the sebaceous matter may, however, under certain conditions act as aids to irritants on the skin.

The vulnerable portions of the skin are the openings of ducts and hair follicles through which certain chemical compounds, especially those which are fat soluble, may easily enter. Thinning or breaks in the cornified layer of the epithelium also act as portals of entry for external irritants.

All matters affecting the defense mechanism and the vulnerable portions of the skin play roles in sensitivity to external irritants. The first of these factors we will consider is race.

It is well-known in industry that the negro is less susceptible to the action of skin irritants than the white man. In such occupations as work on grinders and driers in dye factories, where there is exposure to irritating dust and irritant dyes, many industrial concerns will employ only negroes because by actual experience they have found them to be less sensitive

to skin irritation. Different types of skin even in the Caucasian Race differ in sensitivity to external irritants. Many factories will not employ those with thin, blond skins in occupations where they come in contact with potential skin irritants. Workers having greasy, oily, thick skins withstand the action of such fat solvents as soaps, turpentine, naphtha, benzol, trichlorethylene, and carbon tetrachloride better than those with dry skins. On the other hand, in occupations where oils, greases or waxes are apt to soil the clothing, as for instance, in oil refineries, machine shops, garages, etc., we have observed that those with much hair on the arms and legs and with excessive sebaceous secretion, are more likely to develop acne-like lesions and folliculitis.

In a certain glass factory, where an outbreak of folliculitis occurred among workers whose clothes became saturated with oil, it was noted that the most severe cases occurred among those workers with the most hair on the legs and arms and that the smooth-skinned ones escaped entirely.

In a study of skin hazards among workers with chlorinated naphthalenes and diphenyls, it was found that while all the workers who were exposed for a length of time developed comedones and acne-like lesions, the worst cases occurred among men with dark, swarthy, oily skins, who were in the acne age. The older men, especially those with fair skins, had very few or no pustules at all, but simply yellowish non-inflammatory comedones or cysts.

Various portions of the skin of the same individual differ in susceptibility to external irritants. We have found in our studies that the inner surface of the forearm and the upper arm where the

skin is comparatively thin, were more often affected by occupational dermatitis and were more sensitive to patch tests than, for instance, the skin of the back. We also noted that the palms are very rarely affected by industrial dermatitis, although they are more exposed than other parts of the skin.

While the perspiration normally is a protective agent against external irritants because it dilutes those irritants which are already in solution, yet we noted that workers who perspire excessively are more likely to develop dermatitis from solid substances which require moisture in order to make them irritants, as for instance, calcium oxide which in the presence of moisture becomes slaked lime (calcium hydroxide), also substances, such as sodium carbonate or soda ash, which will only irritate when they are in solution.

A substance in order to affect the skin must wet it and will act on it either by a chemical combination or by extracting moisture or fat from the skin. That means that a substance in order to affect the skin must be more or less soluble or miscible in the secretions of the skin.

Excessive perspiration combined with friction will also macerate the skin and will thus make it less resistant to the action of external irritants.

The pH of the perspiration is of importance in that it affects the solution of irritants on the skin. It has been shown by Talbert and Rosen that the pH of perspiration varies in different individuals, and at different times in the same individual, anywhere from 4.5 to 8—a difference from marked acidity to alkalinity. In a factory manufacturing calcium cyanamide, a fertilizer and a source of commercial ammonia, it was noted that nearly all of the workers affected with dermatitis from this material had an alkaline perspiration as tested with litmus paper in the axilla. One explanation for this may be that the alkaline lime which caused the irritation in these workers was neutralized by those having an acid perspiration. The diet of the worker also influences the pH of perspiration and is in other ways a factor in sensitivity to industrial dermatitis.

Mayer and Sulzberger,¹⁰ in 1931, showed that diet influences sensitization in guinea pigs.

T. Saito⁷ has shown that the sensitivity of the skin of rabbits to croton oil was increased when they had been rendered acidotic by a diet of oats or by per oral administration of hydrochloric acid, or by the subcutaneous administration of a solution of sodium oxalate. He noted that cutaneous sensitivity in rabbits was also increased by rendering them alkalotic by means of intravenous administration of sodium bicarbonate. However, the sensitivity of the skin was reduced even below normal when hydrochloric acid was administered to a rabbit which had been previously rendered alkalotic or when a solution of sodium bicarbonate was administered to a rabbit which had been previously rendered acidotic. He also noted fairly constant changes in the relative proportions of the electrolytes of the skin accompanying the changes in the intensity of the response of the skin to external irritation. That is, he noted changes in the relative proportions of calcium, magnesium, potassium, and sodium in the skin.

In states of heightened sensitivity there was a high calcium-potassium ratio and an increase in the total weight of the calcium, whereas in states of lower sensitivity the reverse was observed. He suggests that nonspecific desensitization might be sought in the rapid reversal of the disturbed acid-base equilibrium in states of heightened sensitivity of the skin.

In performing patch tests, we have taken into account the fact that there are variations from time to time in the pH of the perspiration of the worker, which may make him sensitive to an external irritant at one time and not at another. We have prepared a stock fluid approximating the perspiration in composition and having the following formula:

Sodium chloride	3
Sodium sulphate	1
Urea	2
Lactic acid	2
Olein	2
Stearin	2
Distilled water	1000

We moisten the skin at the site of the patch test, or the material with which we are patching with this synthetic perspiration. If negative results are obtained, a drop or two of acetic acid is added to a

portion of the stock of the synthetic perspiration in order to make it more acid and a drop or two of ammonia is added to another portion of the perspiration in order to make it more alkaline, and the tests are repeated using these solutions to wet either the skin or the material with which we are patching. This procedure has sometimes resulted in positive patch tests under one or the other of the patches. Control patches with these solutions are always performed. We used this procedure for the first time when we studied dermatitis from synthetic resins and we found that in many instances where negative patch tests had resulted from ordinary patches, we obtained positive reactions when the resin was moistened with the acid synthetic perspiration.

The stearin and olein in this fluid are really not necessary because they do not readily disperse in the fluid and hence do not have the same protective and solvent action as the sebaceous and fat secretions of the skin. The fatty and sebaceous secretions of the skin are evenly coated over the surface and they are also in a liquid state. This liquid state of the fatty and sebaceous secretions is apt to make them solvents for fat soluble chemicals coming in contact with the skin and thus cause them to irritate the skin. For instance, in an outbreak of dermatitis occurring among the wearers of certain wrist watch straps which were dyed with amido-azo-toluene hydrochloride, a fat soluble dye, the most severe reactions from wearing these straps and from patch tests with the dye, occurred on two young dark Italian girls who had oily skins.

We have made a list of substances which we have used as patch tests in our various investigations. In this list we give the concentrations of the substances used and the length of time they were allowed to remain on the skin without causing reactions on controls and yet causing reactions on some workers who were exposed to the substances and had dermatitis. These concentrations are not minimum or maximum. In industry, patches were made with the chemicals in exactly the same form in which the workers came in contact with them in the course of their occupations. Many of the chemicals therefore, were applied in the solid state and as many of them are

insoluble in normal perspiration, they caused no reactions on controls. Had many of these water insoluble chemicals been applied in suitable solvents, they would have caused reactions on the controls.

To this list is appended a list of substances and concentrations compiled by Rudolph Mayer, which when used as patch tests on healthy normal skins for twenty-four hours, result in no reaction. If a reaction results after a twenty-four hour period, or if after a longer period of time a reaction develops, then the skin is hypersensitive to these substances.

Age

Age seems to have an influence on sensitivity to external irritants. Most of the workers affected with acute industrial dermatitis are young and new workers. This may be because they have not become immune or hardened to the chemicals, or it may be because they are less careful in handling chemicals. On the other hand, the chronic eczematoid types of industrial dermatitis usually occur in workers of middle age and beyond.

Women are very often irritated by substances in industry with which men usually work with impunity. A woman will notice the slightest irritation of her skin, whereas most men do not.

Season of the Year

Occupational dermatitis is more prevalent in warm weather when little clothing is worn and contact with skin irritants is more likely to occur. Excessive perspiration is also more apt to occur in warm weather.

The presence of other skin diseases, especially of the itching type where scratching tends to rub in any irritant which may be deposited on the skin, also predisposes to contact dermatitis.

Aside from the thinning and breaks of the horny epithelium caused by these diseases, it has been noted that those workers suffering with seborrhea and mycotic infections are more prone to develop industrial dermatitis than those who do not suffer from these conditions.

Cleanliness

This is a very important factor in sensitivity to external irritant. Cleanliness

of the environment, or in other words, clean work rooms, clean floors, clean walls, clean machines and the air kept free from irritating fumes, vapors and dusts, will diminish the sensitivity of workers to industrial dermatitis. Personal cleanliness is of equal importance. The daily changing to clean underclothes and work clothes, cleansing shower baths immediately after work is finished so as to remove potential irritants from the skin, the immediate washing away of accidental splashes of corrosive substances, washing of the hands and cleaning under the nails before eating, as well as sanitary eating places—all are important factors in the prevention of sensitivity to industrial irritants.

In some instances the wearing of clothes saturated with chemicals with which the worker comes in contact during his employment will cause dermatitis in his home. I saw a case where the wife and child of a worker in Halowax had contracted a severe acne on the face, shoulders, and thighs because they came in contact with the dirty work clothes which the worker wore home from the shop and with the dirty underclothes in which he worked and slept.

Allergy

R Prosser White¹ states that the number of well-found instances of sensitivity directly resulting from occupation is almost negligible. He states that this fact stands out prominently when contrasted with the hundreds of chemical substances manipulated by workers daily. Most of these chemicals are harmless to workers under normal conditions but may be injurious to some workers under different conditions. Many cases seemingly due to allergy can be explained by changes in working conditions or changes in the skin of the worker. During the first few years of the existence of the Office of Dermatoses Investigations of the Public Health Service, we took personal and family histories of allergy of all cases of industrial dermatoses which we saw and we were unable to tie up with the cases of dermatitis any such allergic conditions as hay fever, asthma, and eruption of the skin supposedly due to eating such foods as strawberries, fish, tomatoes, etc. We

found no greater preponderance of allergic conditions in the personal or family histories of those affected with industrial dermatitis than in those who were not affected. However, we did find that a very large percentage of our cases of industrial dermatitis had active mycotic infections either of the interdigital spaces of the toes, as evidenced by scaling and cracking or vesicles, or mycotic infections of the groin and other parts of the body. In fact, it has often been difficult and sometimes impossible to differentiate between the lesions of a phytid and a contact dermatitis. While a positive patch test shows a sensitivity of the portion of the skin on which the test is performed to the substances with which the person is patched, a negative patch test is not conclusive proof that the dermatitis was not caused by the substance with which the patch test was performed because the patch does not simulate working conditions and because the condition of the patient at the time the dermatitis was contracted may not have been the same as at the time when the patch test was performed.

Although Bloch found that a sufficient concentration of the poison of *Primula obconica* will produce dermatitis in all people, yet the fact that there is a specific hypersensitivity of certain individuals to the action of many substances in industry cannot be denied. I have seen cases where the mere presence in the same room with dinitro chloro benzol, or with nitroso dimethyl aniline, has produced pruritus in a hypersensitive individual. I also have seen a chemist so sensitive to formaldehyde vapors that when he held his forearm over an open bottle of formalin, one could see the erythema develop on the exposed skin in less than a minute. That this hypersensitivity can be acquired by continued exposure to certain substances is also a fact. The case as cited above developed an allergy after years of exposure. This sensitization may be induced through channels other than the skin. It may occur through the respiratory or gastrointestinal tracts.

The nitro and nitroso compounds are well-known among chemists to be sensitizers. How sensitization to nonprotein substances is brought about has been ex-

plained by Landstiner. He showed that substances unable by themselves to produce antibodies can do so when linked to a true antigen, such as a foreign protein. Parenteral injection of such mixtures gives rise after a latent period to antibodies not only to the protein but also to the nonantigenic substances.

Haxthausen² produced skin allergy to mercury, chromium, and formaldehyde by combining them with horse serum and injecting them intracutaneously. He also obtained similar results by combining mercuric chloride with washed cultures of yeast. Out of fifty cases studied he obtained positive patch tests with mercury on four cases of seborrhea and negative ones in the remaining forty-six not having seborrhea. As the result of these experiments Haxthausen advances the theory that the micro-organisms of the skin may play the part of foreign proteins in uniting with the simple chemical compounds to form complex antigens capable of producing antibodies to the simple compounds. Passive transfers in these cases of hypersensitivity to simple compounds have seldom met with success but desensitization to various chemicals has been reported by R. Cranston Low and Bloch. We have actually seen desensitization occurring under working conditions. We have noticed workers who when they first came to work developed a contact dermatitis which finally disappeared if work was continued. The workers themselves are well aware of this fact and call it "becoming hardened." We have noted that this immunity will last a varied length of time in the worker, that is, if he should be laid off from work for a few days and returns, he is still immune, but if he stays away from work for a longer period—a month or more—he very often has to go through the same "hardening" process.

When we consider the fact that by far the large majority of the cases of occupa-

tional dermatitis are caused by substances such as alkalis, acids, corrosive salts, fat solvents, and dehydrators, then we realize that only a small percentage of the cases of industrial dermatitis is due to allergy. This is not the case among the wearers and users of finished products. Here allergy is the most frequent cause of dermatitis because the finished products are harmless to by far the large majority of the population. Furs, dyes, cosmetics, while worn by millions, cause dermatitis in comparatively few. We have found that when patch tests were performed with fur dyes, leather dyes, and hair dyes on individuals suffering from dermatitis as the result of using them, the positive reactions to the patch tests were not so localized as they were in most of the workers suffering from industrial dermatitis. In the users of these finished products, the reactions from the patch tests often spread diffusely from the site of the patch and sometimes reactions appeared in distant parts of the body and even became generalized, producing elevation of temperature and systemic symptoms, while in industry by far the largest percentage of patch tests performed in cases of industrial dermatitis caused localized reactions only.

Conclusion

Bearing in mind the above factors in sensitivity to external skin irritants, the dermatologist can better treat industrial dermatitis and the industrial physician can, by selecting suitable persons for the various occupations in which there are skin hazards, and by advising proper safety precautions, lessen the occurrence of industrial dermatitis in the United States and save much suffering as well as a considerable portion of the four million dollars which is the estimated annual cost of industrial dermatitis in the United States.

List of Substances and Dilutions and Length of Time They Were Allowed to Remain On the Normal Skin in the Form of a Patch Test Without Causing Reactions But They Did Cause Reactions on Individuals Hypersensitive to Them

LIST COMPILED BY LOUIS SCHWARTZ, SENIOR SURGEON, U.S.P.H.S

Wearing Apparel

Moisten with perspiration, apply to skin, and leave on for as long as five days

Japanese Silk	Acetate Rayon
Italian Silk	Furs
Yellow Silk	Cotton
Wild Silk	Wool
Viscose Rayon	Leather

Hair

Acids

Moisten a piece of gauze and leave on for twenty-four hours

Hydrochloric Acid	1% sol in water
Sulphuric Acid	1% sol in water
Formic Acid	1% sol in water
Acetic Acid	3% sol in water
Oxalic Acid	5% sol in water
Phenol	2% sol in water
Cresol	1% sol in water

Alkalis

Moisten a piece of gauze and leave on for twenty-four hours

Sodium Hydrate	½ of 1% sol in water
Potassium Hydrate	½ of 1% sol in water
Barium Hydrate	½ of 1% sol in water
Calcium Hydrate	½ of 1% sol in water
Ammonia	2% in water of a saturated sol
Calcium Carbonate	3% sol in water
Sodium Carbonate	3% sol in water
Potassium carbonate	3% sol in water
Sodium Meta Silicate	2% sol in water
Tri Sodium Phosphate	2% sol in water

Chemicals

*Moisten solids with perspiration
Leave on for twenty-four hours*

Urea (powdered)	Pure, moistened with perspiration
Formalin	10% of 40 Volume aqueous sol
Sodium Bichromate	3% aqueous sol
Potassium Bichromate	3% aqueous sol
Sodium Sulphide	1% aqueous sol
Calcium Sulphide	1% aqueous sol
Potassium Permanganate	1% aqueous sol
Amm Fluoride	½ of 1% aqueous sol
Calc. Fluoride	½ of 1% aqueous sol
Hydrogen Peroxide	Pure
Zinc Peroxide	Pure Powder
Zinc Oxide	Pure Powder
Barium Sulphate	Pure Powder

Solvents

Moisten a piece of gauze and leave on for twenty-four hours

Furfural	Pure
Pine Oil	Pure
Di-ethylene-glycol	Pure
Acetone	Pure

Trichlor-ethylene	50% in olive oil
Ethylene Di-Chloride	50% in olive oil
Carbon Tetrachloride	50% in olive oil
Kerosene	50% in olive oil
Gasoline	50% in olive oil
Turpentine	50% in olive oil
Benzol	50% in olive oil
Toluol	50% in olive oil
Xylol	50% in olive oil
Naphtha	50% in olive oil
Terpineol	Pure
Fenchyl Alcohol	Pure

Moisten a piece of gauze

Petroleum Products

Leave on for twenty-four hours

Tar	Pure
Asphalt	Pure
Pitch	Pure
Mineral Oil	Pure

Aniline Dyes

Moisten solids with perspiration and leave on for twenty-four hours

Paper Dyes	Pure Powder or Paste
Silk Dyes	
Wool Dyes	
Cotton Dyes	
Rayon Dyes	
Leather Dyes	

Organic Pigments

Moisten pure powder with perspiration and leave on for twenty-four hours

Fur and Hair Dyes

Leave on for twenty-four hours

Para Phenylene Diamine	3% aqueous sol
Para Amido Phenol	3% aqueous sol
Para Ammino-Diphenyl-Amine	3% aqueous sol
Pyrogallol	3% aqueous sol
Logwood Extract	10% aqueous sol
Chestnut Extract	10% aqueous sol
Fustic or Yellow Wood	Pure
Brazil Wood or Red Wood	Pure
Quercitron	Pure
Cutch	Pure
Turmeric	Pure

Powdered and moistened with perspiration

Dye Intermediates

Moisten solids with perspiration and leave on for twenty-four hours

Phenyl Glycine	Pure
Para nitro benzoic acid	Pure
Phenyl Alpha Naphthylamine	Pure
Mono benzyl para amino phenol	Pure
Meta Toluylene diamine	Pure
Anthracene	Pure
Benzidine	Pure
Diamisidine	Pure
Benzanthrone	Pure
Anthraquinone	Pure
Di Methyl Amine	Pure
Amino Azo Toluene	Pure

Beta Naphthol	10% in Olive oil
Mischler's Hydrol	5% in Alcohol sol.
Nitroso di-ethyl-aniline	1% in Alcohol sol
Di-nitro-chlor-benzol	½ of 1% in Alc sol

Rubber*Moisten with perspiration*

Pale crepe	Pure	leave on 5 days
Darker crepe	Pure	leave on 3 days
Smoked sheet	Pure	leave on 2 days
South American para	Pure	leave on 2 days
African wild rubber		leave on 2 days
Balata		leave on 2 days
Gutta Siac		leave on 2 days
Latex	Pure	leave on 5 days

Latex—containing ammonium hydroxide to preserve it	Pure	leave on 24 hours
Mineral rubber	Pure	leave on 48 hours

Rubber Accelerators

Moisten with perspiration and leave on for twenty-four hours

Guanidines	Pure
Thioureas	Pure
Salts of dithio acids	Pure
Thiuram sulphides	Pure
Mercaptans	Pure
Hexamethylene-tetramine	Pure
Aldehyde amines	Pure
Para-nitroso-dimethyl-aniline	2% in Alcohol sol.

Rubber Anti-Oxidants

Moisten with perspiration and leave on for twenty-four hours

Alpha naphthylamine	} Pure
Phenyl-beta-naphthylamine	
Sym di-beta-naphthyl-paraphenylene diamine	
Di-tolylamines	

Explosives

Leave on for twenty-four hours

Di-nitro-toluol	} Saturated alcohol sol.
Tri-nitro-toluol	
Tetryl	Saturated sol in ether
Fulminate of Mercury	} Pure on gauze moistened with persp
Lead Azide	
Lead Styphnate	
Sensol	
Smokeless Powder	

Paints and Varnishes

Leave on for twenty-four hours

Pure paint or varnish on gauze—allow to dry, then moisten with perspiration and apply as a patch

Photographic Developers

Leave on for twenty-four hours

Metal	} 5% aqueous solution
Amidol	

Soaps

Saturate a piece of gauze with solution and leave on for twenty-four hours

White Castile Soap	3% solution
Other non-medicated, non-perfumed soaps	2% solution in water
Medicated or Perfumed soaps	1% sol in water

Resins

Leave on for twenty-four hours

Olibanum	} Pure Powder on gauze moistened with perspiration
Rosin	
Copal

Discussion

DR. HERMAN GOODMAN, *New York City*—It has often been said that there is nothing new under the sun. We take pride in the recent flood of interest in well being of workmen. The program of this session of our society reflects that interest. Our own section and the section on Industrial Medicine and Surgery has papers on industrial skin disease. It surprised me and it may surprise you to learn that the founder of industrial hygiene and sanitation for workmen lived more than 200 years ago and that Ramazzini recognized the primary basis of modern industrial hazards. Bernardino Ramazzini (1633-1714) established the two main divisions of the causes of dire results in the risks of employment. The first was the deleterious nature of the material which the workman must handle, and the second, the strange, improper position of the body required in certain occupations.

In a recent volume, I extracted some of the observations made by Ramazzini on diseases of the skin. There was an excellent example in silk handler's disease which Ramazzini described so well that for hundreds of years all other authors on the subject used his description and his concept of the condition. This constant repetition did not ensure accuracy, by the way, or perhaps the conditions of operation changed with the centuries. In a modern study of silk handler's disease of the skin, for example, the antiseptic used in the manufacture of silk filament to prevent the formation of mildew was found to excite the dermatitis.

It may be taken as a general premise that no one person is immune to all irritants. The matter boils down to the old adage: a large dose of poison may overcome in the presence of great resistance, and a small dose overcomes in the presence of slight resistance. We do not know why resistance changes and a person who has worked for years as a silk thrower, for example, should find that it is impossible to continue at work. Of course, it is not impossible that the chemists in the factory have changed the ingredients of their industrial processes. We have noticed the same thing among nurses or surgeons. They do well in one operating room and fail in another because one hospital uses bichloride, let us say, and the second insists on chloride of lime.

The suggestion we offer is that we must not ignore the chemical reactivity of the skin in health, and the assault on that chemical reactivity by the industrial processes. In the first place, and accounting to some degree for the arrangement of an industrial dermatitis, or any dermatitis venenata for that matter, is the presence of active seba-

ceous glands. The partially lysed modified keratin (we cannot honestly speak of sebum as a secretion) from the hair follicles acts in many instances as stimulant to industrial skin disease. Recall the clinical picture of a hand case. Recall that the dorsum of the hand suffers first. It suffers most. The palm is relatively free. Another picture easily recalled is the fact that across the knuckles where neither hair nor hair follicles exist we have an area of skin which is relatively immune to reactivity. It is an area which suffers last and only as part of an extreme instance of industrial irritation of the skin. The palm which is free of sebaceous material, on the same practical and theoretical considerations, rarely is affected early in an instance of industrial skin disease, or in a mild case. The same applies to dermatitis venenata from rhus.

The facts back of these observations go to the credit of Arnold who studied the hydrogen ion concentration of the skin some years back. The use I have made of his observations is the preparation of creams and lotions, for the prevention of industrial skin disease depends upon the premise that the presence of lysed keratin from the hair follicle is an important factor in rendering the skin subject to irritation. Similar usefulness is accorded to the prevention of hair dye dermatitis, for example.

The physician dermatologist must take advantage of these features as well as the most modern advances in technical chemistry as utilized by the commercial pharmaceutical or cosmetic house which is not restrained from incorporating non-official drugs and chemicals into their products advertised and sold as aiding in the prevention of industrial dermatitis. In general and on the whole, the casual product of a written prescription offered by the physician dermatologist has neither the appeal nor the efficacy of the commercial product. The authority of the physician is reduced in consequence. Further invasion of the patents becomes inevitable.

The dermatologist who seeks to alleviate industrial dermatitis must not wait for the patients to develop the skin disease. Insurance companies and personnel managers are not satisfied with remedial measures. It is equally impractical to discharge workers from key positions or force them into the ranks of the unemployed because they develop a skin disease. Society is not ready to support them either. Hence the hope that only those physicians will undertake industrial dermatological studies who are themselves equipped or are willing to cooperate with others so equipped to combat chemicals with chemicals and prevent rather than cure.

CASE REPORT

ERYTHEMA MULTIFORME WITH SEVERE CONSTITUTIONAL SYMPTOMS

HARRIS W CAMPBELL, M D , PHYLLIS S KERR, M D ,
and
EDWARD H MARSH, M D , Dr P H , *White Plains*

Erythema multiforme is a complex usually with only mild if any constitutional reaction. Cases of this disease with severe constitutional symptoms are sufficiently rare to justify reporting.

The patient was a white girl, fifteen years of age, of a family of better than average economic status. She was robust, and apparently had been previously healthy. Her medical history was negative except that about a week before the onset of her present illness she had had what was thought to have been German measles although that diagnosis had not been confirmed by a physician. However, German measles was prevalent in the community and the mother's description of the girl's illness was a fairly accurate picture of that disease.

On April 8 the patient suffered with headache, fever, sore throat, and enlarged and tender cervical glands. When seen by one of us (C) on the afternoon of that day the patient had an extremely red pharynx with small yellowish white patches on both tonsils. Her temperature was 102° F but no eruption was observed. The white blood count was 12,500 with seventy-five per cent polymorphonuclears. During the evening of the same day an erythematous "measly" eruption appeared on the face and upper extremities.

When seen on April 9 the temperature was 104.5° F, she was suffering with repeated chills and complaining bitterly of sore throat. The eruption at this time had not only extended but had changed its character. The lower two-thirds of the face was covered, as were the extremities, the eruption extending down to the backs of the fingers and on the lower extremities involving the dorsum of the toes. On the arms the eruption was slightly less on the flexor than on the extensor surfaces, on the legs both flexor and extensor surfaces seemed equally involved. Whereas earlier in the same day the eruption had been flat it was now papular and edematous. The face was swollen although individual papules could easily be determined. On the extremities the whole

eruption was erythematopapular with a tendency to coalesce with wheal-like lesions resulting. On the breasts and over the sternum were a few small discrete papules, each one surrounded by a narrow pale aureola. The oral mucosa was spotted with red lesions from pinhead to pea size, the throat was very red and edematous. The patient had a rhinitis and a very marked conjunctivitis, both ocular and palpebral, giving her the appearance of one with an acute attack of hay fever. She was also hoarse. Because of the condition of the throat associated with an eruption a diagnosis of atypical scarlet fever was suggested, but this was ruled out by failure of the blanching test and the subsequent clinical course of the disease.

On April 10 the general condition was even more exaggerated. Fever was about the same, the tendency to chills more pronounced, and the mental attitude of the patient much worse. The general picture was that of a very sick girl. The only change in the eruption was an extension to both palms and soles.

On April 11, the temperature was normal, the edema of the face had largely disappeared, the hoarseness was gone, and the conjunctivitis and rhinitis much improved. The eruption had almost disappeared on the legs and feet although still present on the thighs and upper extremities. At this time also it was well-marked on the trunk. The papulo-urticarial character of the eruption was almost entirely lost and it was now merely an intense erythema. On the trunk gyrate configuration was in evidence. The patient was so much better that she was hungry and had no difficulty in swallowing.

The case was quite evidently an allergic phenomenon with the skin picture of erythema multiforme. Whether the original follicular tonsillitis was part of the general picture or whether the succeeding phenomena were allergic responses to a tonsillar infection may be a matter of opinion. In favor of the latter is the early

blood picture typical of an acute infective process. The subsequent oral and late exaggerated pharyngeal manifestations together with the rhinitis and conjunctivitis were unquestionably allergic. No history could be elicited of the ingestion of any drug or food which could reasonably be expected to have caused the condition.

Conclusion

A well-nourished, previously healthy girl fifteen years of age, suffered with an attack of acute follicular tonsillitis associated with a severe general allergic response as a part of which there was evident the dermatological picture of erythema multiforme.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

A Lingual Story

Who can tell how much truth there is in this woman's story? One part of it seems far-fetched, although my impression, as derived from her personality, is that it is all true. But in psychology this does not matter. Whether it is a dream or a lie it all belongs to the picture. No one can go out of himself in his invention of any story. The material he works with is contained within him. Nor is truthfulness relevant to our present purpose.

One day this patient's mother happened to be suddenly very ill. It was thought that she was dying. So the daughter ran into the street, met a policeman, and asked him to call a hospital ambulance. He first came up to the house, looked the situation over, and then went to the telephone. An intern arrived, examined the old lady and wanted to take her to the hospital. But she refused, and some medicine had to be given to her which improved her acute condition. She remained at home and alive.

About a month later, when our patient, that is the previous patient's daughter, returned late at night from a ball, alone, the above mentioned policeman, stationed in a somewhat dark block, stopped her and asked about her mother's health.

"All right," said the young woman.

"Glad to hear it, but it is all due to me, I saved your mother," replied the guardian of the law.

"How is that?"

"Well, didn't I call the hospital doctor?"

"Yes, and I thank you for that."

"That isn't enough. You must do more than that."

And he, a large and powerful man, dragged this little female rapidly to the most shadowy place, lifted her up and inserted his tongue deeply into her mouth. No mat-

ter how she struggled and tried to turn her head away she could not escape his embrace or his tongue.

He was all excited and did not leave her free until he calmed down. Then she protested and said "Why don't you do that to your wife? I am married and I don't want that sort of thing." To which he answered that it was an honor for her and that he had done the same thing to other women and girls without meeting the slightest opposition.

This may be a figment of this patient's imagination, but it is not an impossible event. After all, policemen have been known to abuse their power and position and this one may have suffered from sexual irregularity which makes only this particular form of gratification acceptable.

But, as this woman herself puts it in her introduction, what about it? What harm has been done to her?

She apparently went home, or rather ran home, slipped into bed at once and said nothing of this occurrence either to her husband or to anyone else. But she was never the same person. A whole year elapsed and during that year she worked out a beautiful psychoneurotic complex.

She had no doubt that now she was suffering from syphilis. Had she not read that this disease may start from the mouth? And did she not have all the symptoms described in the newspaper article?

It all began with a burning of the tongue, the gums, the palate, and continued with a pain in the throat which descended into the chest until now the "entire body" was affected. She was sure to die soon. She observed herself, palpated her body, looked continually into the mirror, and was totally unable to do her housework or to attend to

her husband and child, a girl of eight. She sighed, cried in the day time, and was sleepless at night. She kept on enumerating unceasingly her multiple sufferings in the presence of her child and wanted her sympathy, without, of course, mentioning her secret to her or to anybody in the family.

Finally she went to a physician who examined her "very carefully" and sent her to me with a note about his findings. She did not tell him the first part of her story, the "original sin" and he made no effort to go beyond her superficial complaints.

This medical man was right about the inequality of the patient's pupils. But this condition failed to alarm me, not only because it is sometimes spontaneously changeable and then meaningless, and because it is not always a sign of lues, but also because in this case the left, smaller pupil coincided with opacities present from childhood. As a matter of fact, the patient had but little vision in her left eye.

Her tongue was "abnormal." Yes—and no. She had one of those "chopped" or roughly fissured tongues inelegantly called by the French *langues scrotales*, which are supposed to run in families and are normal with many people. She admitted to have always had it exactly the same way and never to have suffered from it until that fatal, tongue-kissing night. It certainly had nothing to do with syphilis.

Neither the physical examination nor the serological test, done by her first doctor and by myself—not because I regarded it as necessary, but just to satisfy and convince her—showed anything abnormal. The real examination, however, was performed by a mere observation of this patient's behavior of her gestures, her stage-acting. I might say her evidently exaggerated complaints and her insensible anxiety.

But in order to prove the truth of her contentions she sprang a surprise. She dramatically opened the door and brought in her little girl, the presence of whom was unknown to me, saying "Please Doctor, examine her. I am the most unfortunate person, because I have infected her. I really care nothing for myself. I want

you to save my child, although I am afraid it is too late. She is doomed."

One look at the child, a few minutes' conversation with her, revealed the situation.

True, contagion had taken place, but not the one this mother had in mind. Through imitation this eight-year-old girl paraphrased her mother's symptoms entirely. Sometimes she went further and used the exact words and motions and signs and sentimental glances, so carefully studied for a year. She too had lost her appetite, she too was unable to sleep at night. She could neither play, nor run errands, nor go to school. Her tongue and throat and chest were burning "like fire" just like her mother's.

Under Charcot and for many years after him, this would have been a type of hysteria, a term which, together with its companion neurasthenia, has been dethroned or greatly modified.

What was there to do?

At the beginning the condition seemed hopeless. But it yielded surprisingly quickly to treatment, which consisted of a few conversations only. There was a response, a favorable change in the mother, right from the first consultation, even before any explanation was offered. The questioning, the examination, purposely done in such a manner as to change the mother's mind about herself and her girl, already contributed toward a cure. A sincere threat regarding the danger to the child's mind, to her future, expressed with deep persuasion by the doctor, helped. Then a description of the translucent analysis of the patient's make-up and of the mechanism which had brought on her fear. A popular lesson about syphilis showed her how little her condition resembled that of the venereal disease.

Within a short time after the mother was cured the child followed suit and became again the happy, playful, sociable girl she had always been before.

But this patient never wanted to give me the policeman's number, which she said she knew. How significant this fact was I do not know.

The Darkening Horizon—Health Insurance

During the recent national campaign, upon the occasion of the dedicatory ceremonies in Jersey City, President Roosevelt took special pains to assure the medical profession that it would have nothing to fear from his re-election, but could rest assured that it would be consulted and its wishes taken under consideration on the question of medical care in devising means to bring about the goal set for the administration in the domain of social security.

Hardly had the excitement of the election subsided than the *New York Herald Tribune*¹ of November 23, carried a story concerning a project for compulsory health insurance, including "cash benefits in disability and invalidity"—ending with the statement that it can all be conducted on a "pay-as-you-go" plan.

We learn that this story was promoted by the Department of Information of the Social Security Board. It was not published as coming from this Department, it was disguised so that it would appear to have a different origin of issue. This disguise was put on so that the medical profession would not feel that "it had been ditched" by Washington

activity just two weeks following the election, and without even the semblance of that consultation and conference which the pre-election statement implied would take place. From information at hand we confidently predict that there will be more and more intense propaganda along the same lines in the near future, coming from diverse points of issue but all originating in the same place.

We strongly resent this appeal to the public in an effort to form public opinion prior to consultation and conference with the medical profession. We do not blame the head of the administration for all the acts of those of its functionaries who, like Mr. Walton Hale Hamilton, have fixed ideas upon the topic at issue.

On the one hand we are in honor bound to defend the high standards of medical care which we have evolved through decades. We have a duty to the general public to see to it that instead of dropping to the level at which it is held in foreign lands, preventive medicine shall not only maintain its high American level, but be developed even further. We have an obligation to the public to keep them from developing into a nation of "medicine bottle users" in lieu of exact diagnosis and expert treatment of their

¹ "Health Insurance Study is Instituted by Security Board," *New York Herald Tribune*, November 23

ills, both acute and chronic. As a profession we have a tradition to maintain, that those who come into our ranks shall come because they carry eager hands to serve suffering, and are not a job-hunting and job-holding fraternity organized to enhance their economic and financial interests. We want nothing whatever to do with the inevitable dirtiness which the demands for "cash benefits" and "disability and invalidism pay" would bring upon us.

On the Washington scene, examination reveals a curious situation. The "socializers" are actively preparing and issuing their propaganda to convince labor in particular and the public in general that *it wants this legislation*.

On the other hand, President Roosevelt desires no new taxes, and so we confidently predict that the bill for compulsory health insurance will be introduced into Congress in the latter part of its next session and will be so phrased that it will take effect only in January, 1938—thus easing the gradation into additional tax burdens!

Until now President Roosevelt has not said one word that he himself is convinced that compulsory health insurance is the answer to the problem of medical care and service to the American people. Nevertheless, many of the agencies in his administration are actively working for its establishment here.

What shall our attitude be when we are consulted? Will it suffice for us to concentrate only upon a defensive position? A positive position is always better than that of a negative defensive attitude. Shall we content ourselves only with efforts to defeat compulsory health insurance because we know its shortcomings? Would it not be better for us to formulate a positive program and concentrate our best efforts to devise some plan or scheme which, while obviating and avoiding all the known disadvantages inherent in compulsory health insurance, would yet be along lines which without sacrifice of intellectual honesty

and accepted high principles of service, we could honorably afford to support.

The *New York Herald Tribune* of December 1, commenting upon the action of the Social Security Board editorially remarks

To save the medical profession and the nation from the application of another European institution, about as well suited to our temper as peace-time conscription, it seems to us that the doctors will have to consider forthwith how medical, nursing and hospital service can be rapidly extended in conformity with the public interest and with their own professional ideals.

We have adopted the principle that the care of the indigent is the care of the community and for this care the doctor should be paid, and we demand that the highest *quality* of medical care be given those below the "comfort level," at a cost within their means. And since the government considers aid to those below the "comfort level" to be within the domain of the goal set for social security, the government should participate in the payment for this care. Upon any scheme containing these principles we could unite because neither the provisions of our own Booth Report nor the ten-point program of the A.M.A. would be violated in any way.

We are not at this time in position to foretell what organized medicine will do. Having in mind the current political situation with its various cross currents we feel that the time is almost upon us when *action* will be required of us positively to shape our policy. In this policy lies the very future of medicine. Now, it is for us to decide whether American medicine will lead the way, or be a reluctant follower in the developments with which the instant situation is pregnant.

Scientific Unity

Professor Henry de Wolf Smyth's recent statement linking Einstein's theory to medicine contains more than a grain

Water-Borne Epidemic of Tularemia

Tularemia, first described by Pearse in 1910, was, two years later, proven to be an infectious disease caused by a specific organism, the *Bacterium tularense*. At first reported in certain circumscribed sections of our country, its prevalence has spread and until recently, the remote etiological factors were bits by the blood-sucking fly *Chrysops discalis*, the rabbit louse, mouse louse, bed-bug and squirrel flea, all of whom ingest the bacterium from the rodents. The handling of infected rabbits has also produced this disease.

Karpoff and Antonoff¹ report an outbreak of tularemia in Siberia wherein the drinking of infected water was found to be the mode for the spread of the infection. Two groups of workers used two different sources of running water for their drinking supply. In one group, no cases of tularemia occurred whereas in the other all the workers became infected. The water that these later drank showed pure cultures of *B. tularense*, and produced characteristic pathological changes when injected into a guinea pig. Some dead water rats were found in the brook used.

The reporters feel that in this epidemic the portals of entry were the tonsils, mouth, and conjunctival mucosa. The disease itself assumed the angnal, typhoid and glandulo-ocular forms. Here, then, is another factor requiring the vigilance of the health authorities, added to their rapidly increasing epidemiological problems.

Lerische, Jung, and Dupertius¹ afford some pertinent observations on the effects of hyperparathyroidism.

Following prolonged and repeated injections of parathyroid extract in animals who were fed an unrestricted diet they found a marked increase in the calcium content of the arteries and the heart. This effect could be obtained only in adolescent rabbits and young rats whose growth and development, incidentally, were retarded to a considerable degree. A significant finding was that, with the continued injections, the calcium in the myocardium returned toward normal while that in the larger arteries remained high and continued so after the administration of parathyroid extract had been stopped.

Disturbances in calcium metabolism have an effect upon the excitability of the nervous system. Laryngismus, infantile convulsions, and spasmophilia result from a decreased secretion of parathyroid hormone. In the work of Lerische et al. evidence is brought forth to indicate that the arterial system is affected when the opposite situation exists. In view of the reported good results obtained in Raynaud's disease following partial removal of the parathyroid glands,² it is not inconceivable that the vasomotor system is likewise influenced in the hyperparathyroid state. More clinical investigation is needed before diagnostic and therapeutic measures will become practical.

CURRENT COMMENT

"HEARD THROUGH THE DIN for state medicine is a constant crackling about the tragic effects of catastrophic illness. True, unexpected sicknesses wreak real havoc yearly on many low-income families. No one gainsays that. Yet their incidence is easily exaggerated.

Nearly 400 typical and geographically-spaced families with an average income of \$2,748 have been studied by the North-

¹ Lerische, R., Jung, A. and Dupertius, S. M. *Presse Medicale* (Paris) 44 1433, 1936.
² Bernheim, A. R. and Garlock, J. H. *Amer Surgerv* 101 1012, 1935.

Experimental Hyperparathyroidism

The regulation of calcium metabolism is the function of the parathyroid bodies. The clinical manifestations of hypoparathyroidism are known to a much greater extent than those found when the parathyroid glands become overactive. The chemical and histological studies of

¹ Karpoff, S. P. and Antonoff, N. I. *J. Bacteriol.* 32 243, 1936.

of truth As the sciences expand, they inevitably overlap, and each must learn to utilize the others' contributions to the general fund of scientific knowledge

Medicine has frequently been a beneficiary of sister sciences, notably physics and chemistry According to Professor Smyth, "Relativity first suggested that matter could be changed into energy and vice versa, an idea that is fundamental to the current studies of nuclear physics which bid fair to have such great practical importance" in the treatment of cancer Research in telephony has synthesized vitamins Meteorological investigation yields valuable information for the treatment of respiratory disease Obviously there is no such thing as scientific isolation, and the world would be the loser if there were

The question that remains is whether physicians on the whole are equipped to utilize the resources of other sciences for the advancement of their own Regrettably enough, the answer cannot be given in an unequivocal positive While physics and chemistry figure in pre-medical and undergraduate medical education, the need for continuous interest in these subjects is not stressed The average practitioner limits his postgraduate studies to his particular field It does not occur to him to turn his attention occasionally to the nonmedical sciences that have contributed so much to medicine

Professional organizations are not wholly free from blame in this respect It is an unusual program that goes beyond strictly medical boundaries for material Similarly with the colleges For the most part subjects like chemistry and physics are taught as distinct bodies of facts instead of being correlated with healing as living, expanding sciences that are continually altering the environment in which medicine operates and the instruments with which it works All in all, this is a suggestive topic for medical educators—both academic and practical—to consider

Significant Criticism

In spite of general approval of the aims of the Federal social security program, the law in its present form continues to evoke severe criticism Many of those who are most warmly in sympathy with the purposes of the act are most outspoken in their strictures They point out that the law makes no provision for the indigent and unemployed, who are most in need of aid, that many workers who will have to pay in the form of higher taxes and living costs are excluded from benefits, and that costs fall too heavily upon the wage-earner

To the profession, these criticisms are highly significant for they are among the most serious objections raised to compulsory health insurance In their way they are encouraging, for they indicate a growing awareness that the costs of governmental benevolence must be defrayed by the people and that, under our present system of concealed taxation, most levies ultimately fall upon the shoulders of the small consumer "Our present taxes," according to J Weston Walch, "eat up 25 per cent of the national income If all our government bills were being paid, they would consume 35 per cent * * * Taxes, to the average American workman today, mean the difference between poverty and sufficiency"

Obligatory prepayment for sickness would create even more problems than unemployment and old age insurance and give added point to the criticisms directed against the latter For one thing, inability to secure medical care for economic reasons is far rarer than unemployment and needy old age For another, this problem is most acute among the indigent, precisely the class for which the compulsory health insurance systems make no provision Other objections are the difficulties of establishing a sound actuarial basis for sickness insurance, the peculiarly complicated administrative methods required and the demoralizing effect on medical service, which is not as easily or casually distributed as cash benefits

To the Editor

In the November 1 issue of the JOURNAL under "Correspondence" there is a letter of criticism from Dr L F Anderson of Buffalo anent your editorial on nurse anesthetists

I agree largely with your reply to his letter, but I feel that he is correct when he decries the lack of support given to the anesthetics question by the State Society

Why the N Y State Medical Society has been so lax thru all these years in allowing this racket to go on at the expense of the profession is certainly a mystery to me. As the accredited guardian of the rights and prerogatives of its members and the profession at large, I assert that the Society should come out this year definitely and forcibly against permitting an important branch of practice to be handled mainly by nurse technicians, who are not in a position to advance the progress of this specialty

The progress of anesthesia, as you must know, has been so rapid and diversified in the last few years that it should be in the hands of physician anesthetists, and I consider it the manifest duty of the State Society to see that this is brought about as speedily as possible

Yours very truly,

HOWARD T BLAIR, M D

November 21, 1936

Note The activity of the Society depends on the action of its House of Delegates. These voted the introduction of corrective legislation. This is in progress now. Instead of writing

to us about what the Society should be doing, the anesthetists might try an educational campaign to teach hospital executives and directors the need of employing physicians rather than nurses as anesthetists—*Editor*

Do Not Blame the Newspapers

1100 Park Ave.
New York City

To the Editor

The lurid newspaper accounts of the trial of "Dr" Anna Swift before the Court of Special Sessions in New York for furnishing sexual "divertissement" to wealthy patrons by special masseuses do not bring out the fact that it was Anna's status as a licensed physiotherapist which enabled her to establish her own offices. Page 227 of the *University of the State of New York Bulletin* of March 16, 1936, containing the official roster of physicians, osteopaths and licensed physiotherapists, lists Anna Swift under a page heading of "Registered Physicians." Years ago we protested that it is both misleading and unnecessary in the official bulletin for the heading "Registered Physicians" to be continued throughout all its pages. The State Education Department paid no attention to this protest. So do not blame the newspapers when Anna Swift, registered physiotherapist and alleged keeper of a disorderly house becomes publicized as "Dr" Swift.

Incidentally, whence the authority of a physiotherapist, who, according to the law, is himself an agent of the medical profession, to employ assistants and delegate his or her work to them?

RICHARD KOVACS, M D

November 21, 1936

MOTHERS WHO IMPERIL THEIR OWN LIVES

The Maternal Mortality Committee of the Medical Society of the County of Erie reports that the chief dangers to mothers' lives involving the responsibility of the public come from (a) failure of the patient to cooperate with her physician during pregnancy (b) failure of the patient to obtain prenatal care or to realize its importance

or to understand what constitutes a minimum standard of prenatal care (c) danger to mother's life from abortions (at least one-fourth of all maternal deaths in previous surveys were found to be due to abortions) (d) demands painless childbirth at unwarranted risks

western National Life Insurance Company. Major illnesses visit them only once every eleven years and cost an average of but \$280. In other words, out of 572 weekly pay checks, six, or approximately one per cent of them, are lost in the catastrophe. Is there any reason to suppose that such a levy plunges these families into the slough of poverty?"—From *Medical Economics*, November 1936

"ONE OF THE DISTURBING FACTORS of modern life is the habit of discarding individual thought and action, regardless of experience, for thought and action provided and sponsored by groups, associated together along new lines. Nothing is even suspected of having merit unless put forth by some group, especially one with a title that implies a revelation from heaven * * *"—From the *Weekly Roster and Medical Digest*

SAID LORD PONSONBY, sponsor of the euthanasia bill recently *rejected* by the House of Lords in England "I am certain that the time will come when Parliament will have to regulate the matter and I am certain that a measure of this kind will be accepted some day. I am afraid the alliance between prelates of the Church of England and doctors will defeat me, but I think it is not the first time the priesthood and medical men have worked together."

Said the Archbishop of Canterbury "I cannot but think that it is better to leave this difficult and delicate matter in the

hands of the medical profession rather than to drag it into the open and regulate it by legal procedure. In this matter I would trust the judgment and honor of the medical profession."

"IT HAS BEEN SAID that once state medicine got a foothold here, little short of a revolution would uproot it. This is no exaggeration. Take as an object lesson the thousands of people now on relief. They are getting something for nothing. Is it logical to suppose that they will bite the hand that feeds them? * * * The average practitioner does not seek hand-outs from Washington. He recoils from the thought of being *kept*, with all that the word implies. He wants to be left alone to practice independently, to give his best to the profession to which he has dedicated his life * * *"—From the pen of Colonel H. Sheridan Baketel, also in *Medical Economics* of November 1936

ANENT THE PROBLEM OF THE delivery of medical care, *Medical Record* of November 18 states that " * * * The fact is that the medical profession no longer dares to look to the past and to tradition for a solution of this problem. It must rapidly and radically change its social and economic thinking, if it is to remain in the forefront of progress and to help plan an effective medical organization for the future. Otherwise, instead of helping paint this picture, physicians will be fitted into it like parts of a jigsaw * * *"

DOCTORS' LOCK YOUR DOORS

The Doctor's office without attendant without lock and key an open invitation to all who care to enter the delight of petty thieves! exclaims the *Kings County Bulletin*, and adds

One of our members reports the following incident

"A man, evidently aware of the fact that I was not in my office, called some twenty minutes before my office hours and informed the maid who opened the door that he would wait until I arrived. When the maid left the waiting room, the man entered my office, helped himself to a Rochester Castle electric sterilizer and a leather case containing bacterial vaccines (probably would have taken more if something hadn't fright-

ened him) and departed, leaving the front door open (for more thieves to come in). He was about forty years of age, five feet eight inches tall, dark hair, neat appearance and well mannered."

If this "gentleman" should pay a visit to your office, instruct your attendant to detain him and notify the police.

For your own protection, do not leave your office open to the public—For here is another—A doctor enters his office to find a "patient" with a handkerchief over his face. In response to the classic inquiry of "What's the matter with you?" the doctor gets invited to stick 'em up and shell out! He does!

scure and enigmatical and in the end the oracles fell into disuse and the priests who lived in the caves were at last without employment because people ceased to come to them. A new priest appeared, who went out among men teaching them. Mankind followed the new leader who lived among them, partook of their customs, habits, joys, and troubles, and answered their questions before they were asked.

Whither medicine? Where are we going? Why are we going? How are we going? The first three queries I lay in the laps of the bright intellects of medicine. On the last question I submit a few thoughts.

Once there was a large crowd of boys going up a hill. One boy, far behind, was running fast. A bystander asked him, "What's the matter? Why do you have to run so fast?" The boy replied, "I must catch up with the crowd. I am their leader."

It is this type of leadership from which medicine has been and is suffering. Is it not the height of folly to issue edicts to the medical profession assuring them that they are the last court of resort, that their opinion on the interdependence between medicine and the public is final, that their oracular utterances are enduring and eternal? Do not these leaders correspond to the little boy in the rear of the procession?

Rather let us acquire new technics: those of groups dealing with groups. In the process of becoming better known, in coming out of our caves, so to speak, we have need to proceed with care, lest we stumble, for we are treading new ground. We must see that nothing is lost that is still of value in the old tradition, and that the new method does not corrupt the values of the old. To be vocal we must have spokesmen, and they must be the right spokesmen. They must say that which is truly interpretative of us. This done, we have nothing to fear from the term "publicity," anathema as this is and should be, when used for personal aggrandizement.

Many questions have arisen. Perhaps the greatest one has been "Can this thing be done without loss of prestige and dignity on the part of the profession?" This question, I believe, has been answered in the affirmative. In fact it has been demonstrated in New York State, at least, that it can be done to the enhancement of the prestige and dignity of the profession. Certainly we are becoming better known and better understood. We have not lost anything by that, but gained a great deal. The oracle sacrificed everything by remaining

in his cave, he became a suspect because he hid himself and surrounded his function with mystery. People needed leaders they could see, who came and walked with them.

Mistakes have been made in medical economics since the history of medicine has been recorded. They will continue to be made, but reiteration of mistakes is stupid and destroying. Leaders in medical economic thought must have uncompromising vision, fortitude to face the harshest facts, and ability to guide through unknown regions.

But a short time ago our government destroyed many magnificent battleships, because we believed in the word and integrity of other nations. Now, we must replace this navy with another. This mistake cannot be rectified. Each year we accept many graduates in medicine from European universities and license them to practice in the State of New York. Will these nations and these universities reciprocate? Such mistakes are matters of civics. Therefore medical leaders have civic duties. Each year 7500 physicians are graduated into the practice of medicine and only 2500 die. This is a mistake of medical education. Therefore medical leaders have a duty in guiding medical education.

For many years we have had a slogan "militant medicine." This sounds well and always obtains applause. It is similar to the Fourth of July orator whose peroration consists of waving the American flag and praising the constitution. Militant medicine means leadership of the public. It means improvement of our public relations. It means creation of leadership available to other groups than our own.

Too often we have found ourselves leading yes—but the outside group we thought we were leading was sometimes going the other way! For we have been in our cave as to these concerns strictly outside the practice of our art, while others walked and talked with men.

Is not this indeed the "militant medicine" of which we have been hearing so much? Not militant in sham battles, straw men at grips with straw men, but real antagonists on the battlefield of controversial opinion.

For years this change of attitude has only been prevented by a wrong conception of the ethical proscription against advertising which is wholly inapplicable in the circumstances of group activities. The abuses to which the instruments of propaganda have been put have closed our eyes to the values when the method is used in accordance with our ethical principles.

MEDICAL TRENDS

Whither Medicine?

TERRY M. TOWNSEND, M.D., F.A.C.S., *New York City*
Chairman, Committee on Medical Trends,
Medical Society of the State of New York

Medicine is not dependent, neither is it independent. Medicine is interdependent with the public. Without the public there would be no medicine, without medicine, there would be no public.

With a clear understanding of these premises, it is about time that each side stop throwing brickbats at the other. There has never been a full and complete understanding between medicine and the public. The medical man has been so engaged in dealing with the raw stuff of life in all its ungentle profusion that he does not exercise his leadership on the masses in a practical manner. On the other hand, the public has always regarded the physician as one who is content to travel the even tenor of his way, to fraternize with his like, and avoid contacts that are not the obvious ones between physician and patient and not involving him in community responsibility. The physician by instinct, training, and occupation is individually self-reliant, solving each problem as it comes along as an original problem, yet not in an original way. Our habits of thought and action require us to solve these problems by reference to principles, with the insight given by the experience of ourself and others. Within these self-imposed limitations, we are truly free spirits.

We are free because we are disciplined as are no other group of men. The world has yet to learn through bitter experience that the man, group or mob who have freedom without discipline will have discipline imposed upon them from without. It is the human inclination to accept the downhill path.

The query "Whither medicine?" implies "Whence medicine?" for "I have but one lamp by which my feet are guided and that is the lamp of experience. I know no way of judging the future but by the past."

Whence came medicine? From a prehistoric area. As far back as 4000 or 5000 B.C., we have definite knowledge that medicine was practiced in a very practical manner, in conjunction with a liberal mix-

ture of religion and superstition. Even Aesculapian medicine was dedicated to the gods and his daughters Hygeia and Panacea played prominent parts in the faith. It was Hippocrates who discarded mythological gods and taught mere humans to observe disease, learn its manifestations, and apply logical relief. For three hundred years until the death of Galen and his followers, medicine flourished as an art and science. Then came the decline and fall of the great Roman and Grecian civilization and culture; medicine also fell and near died. It required fourteen centuries for medicine to revive and progress. As the social, political and economic tides ran low, so did medicine.

Five centuries is but a tiny period of the world's time, and it may be reasonably accepted that our present culture will not be immediately wiped out. Nevertheless, when, as, and if this decline and fall comes, medicine will fall, but not so low as it did in the fourteen centuries after Galen. If medicine obtains and retains strong leadership, much can be done to prevent its complete abasement and even under the severest blows which culture may sustain, medicine can still hold its prestige.

But medicine, as has been stated, is interdependent with the public. And the public has chosen to take a superficial course in medicine without, at all times, the wisest leadership. Not always, but too often, "health education" has operated as a mere inducement to self-diagnosis. In other respects, of which we are aware, the public has been given erroneous information in the ostensible effort to "educate" them. This is because we have been content to be leaders as individuals of individuals, and have not exercised leadership as a group of other groups. Never have we denied advice or assistance, but have always given it when requested. But we have waited to be requested. Our attitude has been that which Shakespeare describes in the lines—"My name's Sir Oracle and when I open my lips, let no dog bark." History relates that the utterances of the oracles were ob-

Read before the Tompkins County Medical Society, Ithaca, November 19, 1936

scure and enigmatical and in the end the oracles fell into disuse and the priests who lived in the caves were at last without employment because people ceased to come to them. A new priest appeared, who went out among men teaching them. Mankind followed the new leader who lived among them, partook of their customs habits, joys, and troubles, and answered their questions before they were asked.

Whither medicine? Where are we going? Why are we going? How are we going? The first three queries I lay in the laps of the bright intellects of medicine. On the last question I submit a few thoughts.

Once there was a large crowd of boys going up a hill. One boy, far behind, was running fast. A bystander asked him, "What's the matter? Why do you have to run so fast?" The boy replied, "I must catch up with the crowd. I am their leader."

It is this type of leadership from which medicine has been and is suffering. Is it not the height of folly to issue edicts to the medical profession assuring them that they are the last court of resort, that their opinion on the interdependence between medicine and the public is final, that their oracular utterances are enduring and eternal? Do not these leaders correspond to the little boy in the rear of the procession?

Rather let us acquire new technics those of groups dealing with groups. In the process of becoming better known, in coming out of our caves, so to speak, we have need to proceed with care, lest we stumble, for we are treading new ground. We must see that nothing is lost that is still of value in the old tradition, and that the new method does not corrupt the values of the old. To be vocal we must have spokesmen, and they must be the right spokesmen. They must say that which is truly interpretative of us. This done we have nothing to fear from the term "publicity," anathema as this is and should be, when used for personal aggrandizement.

Many questions have arisen. Perhaps the greatest one has been "Can this thing be done without loss of prestige and dignity on the part of the profession?" This question, I believe, has been answered in the affirmative. In fact it has been demonstrated in New York State, at least, that it can be done to the enhancement of the prestige and dignity of the profession. Certainly we are becoming better known and better understood. We have not lost anything by that, but gained a great deal. The oracle sacrificed everything by remaining

in his cave, he became a suspect because he hid himself and surrounded his function with mystery. People needed leaders they could see, who came and walked with them.

Mistakes have been made in medical economics since the history of medicine has been recorded. They will continue to be made, but reiteration of mistakes is stupid and destroying. Leaders in medical economic thought must have uncompromising vision, fortitude to face the harshest facts, and ability to guide through unknown regions.

But a short time ago our government destroyed many magnificent battleships, because we believed in the word and integrity of other nations. Now, we must replace this navy with another. This mistake cannot be rectified. Each year we accept many graduates in medicine from European universities and license them to practice in the State of New York. Will these nations and these universities reciprocate? Such mistakes are matters of civics. Therefore medical leaders have civic duties. Each year 7500 physicians are graduated into the practice of medicine and only 2500 die. This is a mistake of medical education. Therefore medical leaders have a duty in guiding medical education.

For many years we have had a slogan "militant medicine." This sounds well and always obtains applause. It is similar to the Fourth of July orator whose peroration consists of waving the American flag and praising the constitution. Militant medicine means leadership of the public. It means improvement of our public relations. It means creation of leadership available to other groups than our own.

Too often we have found ourselves leading, yes—but the outside group we thought we were leading was sometimes going the other way! For we have been in our cave as to these concerns strictly outside the practice of our art, while others walked and talked with men.

Is not this indeed the "militant medicine" of which we have been hearing so much? Not militant in sham battles, straw men at grips with straw men, but real antagonists on the battlefield of controversial opinion.

For years this change of attitude has only been prevented by a wrong conception of the ethical proscription against advertising which is wholly inapplicable in the circumstances of group activities. The abuses to which the instruments of propaganda have been put have closed our eyes to the values when the method is used in accordance with our ethical principles.

The day of mute leadership is gone. The leader of today and tomorrow will be persuasive, he will reach out and ask for the understanding of others, he will never claim exclusive rights to be heard, he will lead by right of his superior reasons. We have nothing to fear in becoming better known.

The method is not so new as we may think. It was mentioned by St. Matthew when he said:

"Neither do men light a candle and put it under a bushel, but on a candlestick, and it giveth a light unto all that are in the house."

Two years ago, men of vision in the Medical Society of the County of New York saw the need for a change in the attitude which had pervaded organized medicine. That organization entrusted to Dr. James F. Rooney and a committee denominated as Committee on Trends in Medical Practice, the setting up of machinery to make organized medicine vocal and persuasive. On January 15, 1935, this committee established a Public Relation Bureau "for the purpose of bringing about a better understanding on the part of the public of the aims and purposes of the medical profession." Mr. Dwight Anderson was selected as director of the bureau and has developed a technic to carry out its purposes. After Dr. Rooney's resignation I was named as the chairman of this committee,

which consists of the chairman of every standing committee of the State Society, and four other members. The personnel at the present time consists of Drs. Groat, Hambrook, Nelms, Farmer, Elliott, Simpson, Kopetzky, Kosmak, and Jewett.

Thus, the committee has the advantage of the advice and assistance of the chairman of all standing committees, together with that of other individuals selected because of certain specific contributions to our work, which they are known to be able to make.

In conclusion, "whither medicine" and "how are we going" depends upon how closely we adhere to the following basic principle: the public needs to be told what are their questions, and they must be told the answers, and they must be persuaded to act in accordance with the answers.

The old method was informative, the new method is persuasive. The old method tended to make the doctor admired and respected. The new method aims to make him also better understood.

The old method tended to differentiate him from the public, to place him on a pedestal or in a cave—aloof. The new method tends to identify him with the public by the very effort of persuading them.

The old method was by way of edict and fiat. The new method is by way of explanation and understanding.

TAKING THE SOUL OUT OF MEDICINE

Those who talk so glibly of making over this profession of ours—this profession rich in traditions, this profession which has attained such noble worth, this profession actuated by kindness and sympathy, this profession whose only passwords are mercy and pity—lose sight of the art of medicine, declared Dr. Maxwell Lick, of Erie, Pa., in his presidential address to his state medical society. They would by a stroke of the pen destroy this almost divine principle, they would reduce to a formula, he said, all these human attributes of kindness, pity, and mercy. They would put the matter on a business basis under the assumption that only scientific medicine need be applied to the sick in order to affect a cure. What an abysmal misunderstanding of the principles involved! What gross injustice and what cruel denial would result to many, many personalities! The art of medicine and its application must remain unchanged. Nothing must make unheard those words so

often expressed by the sick: "Doctor, I'm so glad you have come." There is wrapped up in that one sentence the epitome of the medical art which has existed through the centuries. It is akin to the child who reaches out his hands to his mother and finds solace and understanding in her arms.

The art of medicine has not changed. The passwords of mercy and pity are the same today as in the days of Hippocrates and the physician of the old school. These qualities of the human soul must not die if the art is to exist. Would you have me believe, he asked, that they can be taken over by the politicians and bureaucrats? Would you have me suppose that they can be reduced to a business formula? Would you have me think that they can be turned on and off by a switch? I call you to witness that this can no more be done without debasing the quality than one can stifle the love in the human breast for its Creator without dwarfing the soul.

PNEUMONIA CONTROL PROGRAM

Handbook on the Nursing Care of Pneumonia *

EDWARD S. GODFREY, JR., M.D., *Albany*
Commissioner New York State Department of Health

Foreword

This Handbook has been prepared under the joint auspices of the Committee on Public Health and Medical Education of the Medical Society of the State of New York, the New York State Nurses' Association, the New York State Department of Health, the General Advisory Committee on Pneumonia Control of the New York State Department of Health, and the Nursing Advisory Committee to the Bureau of Pneumonia Control of the New York State Department of Health.

In preparing this Handbook a selection has been made of those medical and nursing aspects of pneumonia with which the nurse should be familiar in order that she may render effective care to her patients and furnish the physician with pertinent information in his absence. An attempt has been made to present the subject in a comprehensive manner in order to make it equally of interest to the nurse practicing in the hospital and in the home.

It is assumed that each nurse will be thoroughly familiar with the technical details of her work in her chosen field, whether it be caring for private patients, hospital, public health, or visiting nursing. Also, no attempt has been made to discuss in detail many of those fundamentals of nursing care with which the graduate nurse is essentially familiar, even though their ap-

plication may be important in the treatment of pneumonia. A few words cannot be substituted for years of sound training, nor can they convey the qualities of personality and of understanding, particularly of the social and psychological aspects of her work, which are equally important to the nurse.

Those interested in further study, either of the subject of pneumonia or of the various broad aspects of nursing, are referred to the section on "Suggestions for Reading from Authoritative Sources," which is appended.

The Division of Public Health Nursing and the Bureau of Pneumonia Control are indebted to the members of the Nursing Advisory Committee and its subcommittee on the preparation of the Handbook for their assistance in collecting and compiling the material herein presented. They are also indebted to numerous individual members of the medical and nursing professions for their careful review of the Handbook in its preliminary stage and valued comments, many of which have been incorporated in the text. To the officials of the Metropolitan Life Insurance Company thanks are due for printing the Handbook, thus making possible its wide distribution.

MARION W. SHEAHAN, R.N.
Director, Division of Public Health Nursing
EDWARD S. ROGERS, M.D.
Director, Bureau of Pneumonia Control

Handbook on the Nursing Care of Pneumonia

It is understood that the nursing care of pneumonia is carried out under the orders of the attending physician and that considerable variation will be encountered between various methods of treatment which may be equally effective. The following discussion,

wherever it encroaches on this field, is intended solely as background material representing in general a conservative view.

Inasmuch as the rationale of nursing care depends on the medical aspects and treatment of the disease, the present review is arranged in such a manner that the medical and nursing aspects are dealt with in sequence under each major heading in order to indicate their interrelationship.

I Definition

Pneumonia is a disease characterized by

*Reprinted from Circular 19
issued by

Bureau of Pneumonia Control
DIVISION OF COMMUNICABLE DISEASES
and the
DIVISION OF PUBLIC HEALTH NURSING
1936

inflammation of the lung, high temperature, and toxemia. It is most prevalent in late winter and early spring. It is often fatal.

II Etiology and Prevention

Medical Aspects

A Causative micro-organisms

1. *Pneumococcus* Types I, II, III, or Group IV (including Types IV to XXII) cause the majority of cases of so-called "lobar pneumonia."

2. Other micro-organisms, such as *streptococcus hemolyticus*, *staphylococcus*, *Friedlander's bacillus*, and *influenza bacillus*, are occasionally encountered.

B Communicability There is sufficient evidence to justify the conclusion that pneumococcus pneumonia is a communicable disease.

C Source of infection

1. Respiratory secretions of infected individuals convalescent and healthy carriers.

2. Probable paths of transmission: (a) Direct by droplet infection. (b) Indirect through contaminated articles or dust in contaminated surroundings.

D Predisposing factors It is generally felt that infection resulting in pneumonia is somewhat dependent on the existence of certain predisposing conditions which act through lowering resistance of the host and increasing his susceptibility to this particular type of infection. Specifically these conditions are thought to be such infections as the common cold, grippe, influenza, measles, and whooping cough. The postoperative period, chronic debility, abnormal fatigue, overexposure, chilling, and alcoholism are also generally considered important in this respect.

E Preventive measure (1) Maintenance of bodily resistance through adequate personal hygiene which includes rest, nutrition, exercise and warmth. (2) Elimination of focal infection. (3) Avoidance of predisposing conditions. (4) Protection of individuals with lowered resistance from unnecessary exposure to pneumonia cases or possible carriers.

Nursing Aspects

B and C Communicability and source of infection Communicable disease technic is indicated in handling a pneumonia patient so that spread of infection either by droplet or by contact with respiratory secretions through contaminated articles may be prevented. In this connection the following directions should be observed:

1. Isolate patient in bed and in a room by himself. If this cannot be done, separate the beds as far as possible and place a screen between them or stretch a sheet from headboard to footboard on the side of the bed. If the beds cannot be sufficiently separated, arrange them so as to bring the head of one opposite the foot of the other and then separate them by a screen or a sheet as suggested.

2. Keep all unnecessary persons and articles out of the sickroom at all times.

3. Observe the fundamentals of communicable disease technic with respect to:

(a) Wearing a gown and face mask when caring for patient. The practicability of masks is a matter of controversy. If they are used their value depends largely on the proper technic, to cover both nose and mouth, to avoid contamination of the side worn next to the face and avoid saturation with moisture by frequent changes.

(b) Thorough washing of the hands with soap and water after caring for patient.

(c) Proper care and disposal of respiratory secretions.

(d) Thorough scalding and washing of dishes used by patient.

(e) Thorough scalding and washing in soap and hot water of all bedding and linen used by patient.

(f) Thorough airing and exposure for two to three hours to the strong sun out of doors all articles which cannot be washed.

(g) Proper cleaning, airing, and sunning of the sickroom at termination of illness.

D and E Predisposing factors and preventive measures The nurse, whether employed in public health work or not, has a distinct responsibility, as also has the physician, in the dissemination of sound public health knowledge. Accordingly the nurse can assist in the prevention of pneumonia by teaching:

1. A proper regard for pneumonia as a communicable disease.

2. The dangers of unnecessary exposure to new environments (persons and places where pneumonia germs may be picked up) on the part of individuals suffering from severe colds, grippe, influenza, measles, whooping cough, overfatigue, etc. (Rest in bed not only provides desirable isolation but also constitutes one of the best treatments for such conditions.)

3. The recognition of the dangers of neglecting a cold accompanied by fever, malaise, or other constitutional symptoms. The potential seriousness of these symptoms should be stressed and medical attention advised.

4. The principles of general sound health and hygiene.

III Diagnosis

Medical Aspects

A Clinical The diagnosis can often be made on symptomatology alone—in fact, the very early diagnosis must usually be so made. The symptoms may appear singly or in combination and may vary considerably in intensity. Definite physical signs may be several days in developing. To await these may mean loss of extremely valuable time. The occurrence of any of the following symptoms should arouse the suspicion of pneumonia:

1. Sudden elevation of temperature.

2. Chill.

3. Pain in the chest (or side).

4. Blood tinged or rusty appearing sputum.

B Bacteriological

1. Prompt bacteriological studies are essential to adequate treatment on a scientific basis.

2. Sputum examination. Specimen should be ob-

tained as early as possible and sent to an approved* laboratory for typing.

3 Blood cultures should be taken. These are of importance not only in diagnosis and prognosis but also in determining the course of treatment.

4 In absence of a sputum specimen a throat swab taken during the act of coughing should be sent to the laboratory immediately for culture.

5 The most rapid and efficient diagnosis may be made from sputum. Other methods are likely to be laborious and slow. Therefore every effort should be made to obtain such a specimen since many valuable hours may thus be saved. Strapping application of a chest binder, local heat or codeine as a means of easing pleuritic pain and permitting coughing may facilitate the securing of the specimen.

Nursing Aspects

A Clinical symptoms The significance of a sudden elevation of temperature, a chill, pleurisy, or blood-tinged sputum, even though they be mild, should be thoroughly appreciated. The physician should be informed of their occurrence at once. If no medical attention has been secured, its importance should be explained and such attention obtained without delay. In the meantime, strict rest in bed is essential.

1 Even one or two of these symptoms should arouse the suspicion of pneumonia and make medical attention imperative.

2 The alert nurse may aid in the saving of valuable time by procuring medical attention early.

3 Pending the arrival of the physician, certain of these symptoms may require palliative treatment.

(a) Patient's apprehensions may need to be allayed by appropriate reassurance.

(b) Chill may require treatment. If so, the following measures should be employed:

(1) Use external heat, warm blankets, jackets, stockings, hot water bottles, etc.

(2) Give warm drinks if there is no vomiting.

(3) Take temperature, pulse, and respirations immediately following the chill and again one-half hour later. Take and record these at four-hour intervals at least or more frequently if there is reason to suspect a significant change.

(4) At end of chill remove external applications to avoid unnecessary hyperpyrexia. Change wet clothing. Give alcohol rub if indicated.

(5) Make a careful record of all significant symptoms noted and data obtained.

(c) Some relief from pleurisy may often be obtained by having the patient lie on the affected side, although in an occasional case the opposite position will be found more effective. This depends somewhat on whether the diaphragmatic or thoracic pleura is affected.

B Bacteriological diagnosis 1 Sputum should be secured as soon as possible in anticipation of the physician's request for it. Collect the first specimen possible. Even though it is poor, do not discard it until you have obtained a better one.

(a) A sterile petri dish or a clean wide-mouthed container should be on hand to collect the sputum. It should not contain any disinfectant solution.

(b) Patient should be instructed to cough deeply in order to raise sputum from the bronchial passages. Saliva and postnasal discharges are undesirable. They are of doubtful value and may even be misleading.

(c) If pain prevents deep coughing it may be sufficiently relieved by turning the patient over on his affected side, though more elaborate procedures may be required.

(d) If a specimen is ordered sent to the laboratory it should be plainly labeled with such information as name and address of patient and of physician, date and time of day sputum was collected and kind of examination requested. If there is a delay in sending the specimen to the laboratory, it should be stored in an ice chest.

3 Other bacteriological procedures

(a) Blood culture is usually taken by the physician with the assistance of the nurse, who should be careful to observe the following precautions:

If an alcohol lamp or other flame is available, flame the mouth of the culture flask or bottle immediately before and after the blood is added. Do not attempt to flame cotton plug as this almost always leads to burns, trouble and ultimate contamination of the specimen. Do not use any kind of flame in the same room with oxygen equipment. (See Section VII.)

(b) Throat culture is usually taken by the physician. Taking such a culture from small children will be greatly facilitated if they are first rolled securely in a folded blanket or so-called mummy bandage."

IV Clinical Course

Medical Aspects

A General appearance and condition

1 Face may be flushed and somewhat cyanotic. Lips and nail beds may become cyanotic.

2 Expression is anxious, due to the feeling of insecurity caused by embarrassed respirations.

3 Herpetic vesicles may appear on lips and sometimes elsewhere on the face.

4 Tongue may be heavily furred and is often dry. Sordes accumulate.

5 Nostrils dilate with inspiration.

B Cough and sputum

1 During the acute stage of the disease the cough may be frequent and productive of thick, viscid, blood-tinged sputum which the patient often has difficulty in raising.

(a) Medications usually are directed toward the relief of cough (codeine—rarely morphine) and the loosening of sputum (expectorants).

(b) Sputum usually is heavily laden with causative bacteria.

2 After the crisis the cough is likely to be easier and productive of large amounts of mucopurulent sputum.

C Temperature

1 May rise rapidly after onset to 103° to 104° F. It is usually maintained at a relatively high level with slight remissions during course of acute disease.

2 Is frequently irregular and lower in elderly or debilitated patients.

D Pulse

1 Frequency. Usually varies in direct ratio to the temperature, although the rate rarely exceeds 120 to 130 in favorable cases.

2 Character. Is usually full and bounding but may become small and feeble in cases terminating fatally.

3 Opinion varies about the use of digitalis or other cardiac stimulants.

E Respirations

1 Frequency. Is usually markedly increased, 25 to 40 per minute.

2 Character. Shallow dyspnea may be marked.

F Nature of recovery

1 May occur either by crisis or lysis. The former is somewhat more frequent in lobar pneumonia.

2 Character of crisis:

(a) Usually occurs between fourth to tenth days of illness.

(b) Temperature, pulse and respirations drop rapidly to normal to nearly normal or even to subnormal.

(c) General evidence of toxemia disappears.

(d) Crisis is occasionally accompanied by transient symptoms of shock, i.e. feeble pulse, drop of blood pressure, profuse perspiration.

*In New York State diagnostic laboratories approved by the State Department of Health for sputum typing are widely available. Most of these have arrangements for night and holiday service.

(e) Patient usually falls into a profound natural sleep
 3 Lysis is characterized by a gradual return of temperature to normal or nearly so, over a period of days

Nursing Aspect

A General Nursing Care 1 Rapid pulse, cyanosis, and delirium may require oxygen treatment (See Section VII)

2 Mouth hygiene is important for comfort of patient. It may also be a factor in preventing the extension of infection into adjacent organs, i.e., sinuses, middle ear, mastoid, etc. The mouth should be cleaned as often as necessary to keep mucous membranes clear and moist.

3 Nose should be kept clean and clear to eliminate dangers and discomforts of mouth breathing

4 Maintenance of proper room temperature (66°-70°F) and of humidity (40-60 per cent) is of importance not only to the patient's comfort but also to a healthy condition of the respiratory mucous membranes. Moisture may be more or less automatically regulated when plenty of fresh outdoor air is obtained. However, the room should not be allowed to get too cold or the patient to be exposed to a draught. Artificial devices in the room to supply moisture may be of some help

B Cough and sputum 1 Care and disposal of sputum or other infected material

The following directions should be observed

(a) Sputum cup

(1) Keep the cup easily accessible to the patient
 (2) If metal containers with paper fillers are used clean daily by washing them with soap and hot water. If they are grossly contaminated, sterilize them by boiling for 10 minutes or soaking in 2 per cent compound cresol solution for 20 minutes before washing.
 (3) Remove paper fillers from metal container with forceps and securely wrap them in several layers of paper and burn them. If sputum is copious, a layer of cotton, paper handkerchiefs, or a base of sawdust or sand will help to absorb it.

(b) Provide mouth wipes of paper tissue or old linen or muslin

(1) Hang a paper bag at side of bed, within easy reach of the patient, to receive these when used.
 (2) Wrap bag and contents securely in paper and burn them.

(c) It is desirable to help the patient to use the sputum cup or mouth wipes in order to conserve his strength. If the patient is weak or very ill such assistance is imperative.

(d) Wrap carefully in paper and burn other infected material such as nasal discharges, dressings from ear infections, abscesses or empyema drainage.

(e) Carefully wash the hands after handling infected material or caring for the patient.

(f) When working close to the patient his head should be turned to one side or his mouth lightly covered with paper tissue or cloth to protect attendants from direct cough.

2 A weak or very ill patient should be turned on his side periodically and encouraged to cough and raise sputum. Secretions should not be allowed to accumulate in respiratory passages to the point of causing rattling or "moist breathing." However, it will not always be possible to prevent this.

3 Bedding and linen used by the patient should be cared for as noted in Section II

C Temperature Rectal temperature, pulse, and respirations should be taken and recorded at four-hour intervals unless otherwise ordered, or unless the patient is sleeping.

1 Sudden and marked changes in the temperature should be checked, preferably with a different thermometer.

2 The physician may leave a standing order for sponge baths or alcohol rubs for excessive temperature.

3 A fall in the temperature unaccompanied by a fall in the pulse rate may be an unfavorable sign and should be reported immediately.

D Pulse 1 Should be regular and should not exceed 120 to 130. Readings should be made when the patient is quiet and not after exertion, such as a coughing attack.

2 It is best to count the pulse for at least a full minute to insure accuracy.

3 Any appreciable change in character should be reported.

E Respiration May be embarrassed by pleurisy or by abdominal distention. Orders should be obtained in advance for treatment of these conditions.

2 Patient should not be permitted to accumulate mucus in bronchial passages and should be encouraged to cough and raise sputum at regular intervals.

F Nature of recovery 1 Crisis General care

(a) Keep patient warm and dry
 (b) See that the conditions are favorable for sleep
 (c) Keep careful and complete notes of the patient's condition

2 Bear in mind that crisis or lysis is only the start toward a return to health. Many days requiring skillful care still lie ahead.

V General Treatment

Medical Aspects

A Pleurisy

1 Is present in the majority of cases over area of infection. May persist from one to two or three days.

2 Varies in intensity but is frequently extremely severe.

(a) Is somewhat amenable to chest binder, strapping, codeine or morphine, heat or counter irritants.

(b) Pneumothorax or diathermy are occasionally employed.

3 Is serious because

(a) It wears patient out.

(b) It contributes to anoxemia through embarrassed respirations.

(c) It prevents adequate coughing and bronchial drainage and thus may favor bronchiogenic spread of infection.

B Distention

1 Is generally encountered during height of acute disease with other symptoms of toxemia.

2 May be prevented or somewhat lessened by

(a) Adequate elimination by bowel often secured

by adequate enemas and by adequate fluid intake.

(b) Avoidance of gas forming food

(c) Adequate salt intake (5-10 gm daily may be prescribed)

3 Treatment Prescribed by the physician and subject to much variation. It may include stipes, enemas, colonic irrigation and medication such as hypodermic pituitrin or physostigmine (eserine).

4 Serious because

- (a) It is an index of profound toxemia.
- (b) It causes respiratory embarrassment by pressure upon the diaphragm
- (c) It causes circulatory embarrassment through similar mechanism
- (d) It interferes with rest and adequate fluid intake

C Rest

1 This is of fundamental importance since the patient's entire energy should be conserved for the purpose of combating the infection.

2 Insomnia and restlessness may be controlled by oxygen and appropriate medication, such as barbiturates or other hypnotics

3 Delirium.

(a) Is often due to anoxemia and may be amenable to oxygen treatment.

(b) May require strong sedative and rarely restraint.

(c) Requires constant attendance

D Nutrition

1 Anorexia is usually profound during acute stage of disease.

2 High caloric intake is generally considered unnecessary during acute disease of short duration

3 The diet should be liquid

4 Fluid intake should exceed three liters a day unless there are cardio-renal complications

5 Alcohol is not generally prescribed unless specially indicated

E Elimination

1 Urine

- (a) Output should be closely followed
- (b) Is often scanty and of high specific gravity
- (c) Complete retention is not infrequent.
- (d) Incontinence may occur

2 Bowels

(a) Constipation is frequent.

(1) Usually can be avoided by adequate fluid intake and daily enema.

(2) Laxatives if prescribed preferably should be mild.

(b) Diarrhea and incontinence may occur

3 Skin

Fluid loss through diaphoresis is often excessive. It may be somewhat controlled by adequate salt intake (5-10 gm daily) and by proper room temperature and ventilation

Nursing Aspects

A Pleurisy Orders for treatment should be obtained from the physician. If a binder is ordered, a scultetus (many-tailed) binder will be found most suitable. While awaiting orders, some temporary relief may be obtained by application of local heat and by turning the patient to the position of greatest relative comfort.

B Distention Orders for treatment should be obtained in advance from the physician. The usual procedures are use of a rectal tube (soft and of large caliber), turpentine stupes, enemas of various compositions, and medication

C Rest 1 To provide for the patient the maximum rest compatible with adequate nutrition and elimination is the fundamental purpose toward which all nursing procedures should be directed. This may necessitate the modification of strict routine care. For example, rest is more important to the patient than a bath at a fixed hour

2 Energy of the patient should be conserved by

(a) Anticipating his needs so that he does not have to waste strength reaching for things or trying to attract the nurse's attention

(b) Using a drinking tube or feeding cup to give fluids and all nourishment

(c) Keeping patient in optimal position for comfortable breathing, on side or back with slight elevation by means of a gatch bed or pillows

(d) Assisting patient in turning and moving in bed

(e) Keeping room at optimal temperature and humidity (see Section IV) and keeping patient warm but not overheated

(1) If semi Fowler's position is employed, a flannel cape or nightgale may be useful

(2) Direct draughts on patient should be avoided by placing a screen between the bed and windows or open doors

(f) Excluding all visitors in so far as possible.

3 A delirious patient should, under no circumstances, be left alone

D Nutrition 1 Forced fluid (3-4 liters) will usually be ordered. A definite plan should be formulated for giving these amounts, taking into consideration the importance of rest. Small amounts given rather frequently are preferable to large amounts given less often. A supply of fresh, cool water should always be readily accessible.

2 Diet. Orders for diet should be obtained from the physician. It is usually liquid and may include fruit juice, milk, eggnog, malted milk, etc., which may or may not be re-inforced with lactose. Broth, ginger ale, and weak tea are often given.

E Elimination The nurse should observe the following instructions

1 Urine.

(a) Provide bedpan or urinal for patient.

(b) Keep careful record of daily output

(c) Report failure to void over 12 hour period or evidence of a distended bladder

(1) Patient may have marked retention and yet no conscious desire to void.

(2) Patient should be catheterized as ordered. Surgical aseptic technic should be employed.

2. Bowels

(a) Give enemas as ordered

(b) Provide bedpan for the patient. Do not allow him to sit up

3 Skin

(a) Give cleansing bath daily

(b) Give special care to bony prominences to prevent pressure sores

(c) If excessive perspiration or incontinence occurs bathe and dry the patient and change gown and linen as often as necessary

F Instruction to family Members of patient's family or others assisting with the nursing care should be fully instructed in these technics. Directions should be simple, explicit, and accompanied by demonstrations. Particular emphasis should be given to communicable disease technic, feeding, changing position and bedding, and using the bedpan

*VI. Specific Serum Treatment**Medical Aspects**A Antipneumococcus serum available*

1 New York State Department of Health at present provides Type I antiserum. Other types will probably be available in the future

2 Commercial companies and certain other health departments at present produce antisera for Types I II V VII and VIII

B Technic of administration

1 Serum should be used only in cases properly typed

2 The efficacy of serum treatment varies in direct proportion to the duration of the disease at the time of serum administration. The earlier in the stage of the disease the serum treatment is instituted the more effective it is.

3 Tests for sensitivity to horse serum should be made.

(a) History should be taken for allergic phenomena (hay fever, asthma, angioneurotic edema, urticaria) and for previous serum treatment.

(b) Skin test and eye test for sensitivity to horse serum should be made.

4 Serum should be maintained at body temperature and administered intravenously very slowly.

5 Complete instructions accompany each vial of serum. These should be read carefully by those unfamiliar with the use of serum.

6 Hypodermic syringe containing 1 cc. of 1-1,000 epinephrine solution (adrenalin) should always be kept on hand throughout skin testing and serum administration for treatment of possible severe reactions.

C Serum reactions

1 Acute anaphylactic

(a) Are rarely encountered if proper precautions are observed.

(b) Time of occurrence is usually within the first few seconds or minutes of administration, but an hour may elapse before the reaction takes place.

(c) The manifestations are

(1) Sense of substernal pressure, difficulty in breathing, and cyanosis

(2) Rapid, thready pulse

(3) Abdominal, lumbar, or bladder cramps

(4) Urticaria

(5) Anxiety, restlessness, and sweating

(d) Though rare and usually avoidable, these reactions may be violent and result in death unless proper precautions are observed.

2 Thermal

(a) Time of occurrence is from one half to one hour after injection of serum.

(b) The principal manifestation is a chill of from 15 to 30 minutes' duration, followed by a rapid rise in temperature of short duration.

(c) Are rarely serious but may require heroic measures to reduce hyperpyrexia, since deaths from this cause have been reported. Methods most readily available are exposure of patient by removal of bed clothes, alcohol sponges, ice sponges, or ice enemas.

3 Delayed serum sickness

(a) Time of occurrence is usually from four to 14 days following serum injection.

(b) The manifestations are

(1) Moderate temperature

(2) Urticaria.

(3) Painful and swollen joints.

(4) Painful and swollen glands.

(c) Is usually of two or three days' duration fairly mild (when concentrated and refined serum is used) and amenable to appropriate medication. Never known to be fatal.

D Effects of serum treatment

1 If given early on first or second day it may be expected to

(a) Cause critical fall in temperature, pulse and respirations, and also disappearance of toxic symptoms.

(b) Prevent spread of infection to other lobes.

(c) Sterilize the blood stream.

2 If given on third or fourth day, similar results may be obtained but are less certain.

3 If given after fourth day, its value is very questionable.

4 It may not affect course of resolution unless given early enough to prevent the occurrence of much consolidation.

Nursing Aspects

B *Technic of administration as applied to nurse* 1 The nurse should assist the doctor in every way possible, though the extent of assistance requested will vary widely with individual physicians.

2 Surgical aseptic technic should always be observed.

3 Patient should be kept calm and quiet. Apprehension should be avoided.

4 The assisting nurse should observe the following directions:

(a) Be sure to have a hypodermic syringe with epinephrine (adrenalin) ready for instant use and within easy reach of the physician before he begins either skin tests or serum administration. Epinephrine (adrenalin) that has turned dark or muddy has oxidized and is practically of no value.

(b) During skin or eye tests previous to serum administration, watch the patient to see that he does not rub his arm at the site of injection, or his eye. False readings may result if he does.

(c) Sterilize the syringes and needles. Plain water left in syringes, needles, or tubing will precipitate protein in the serum. To avoid this, rinse with sterile physiological salt solution before using.

(d) In order to maintain serum and salt solution at approximate body temperature

(1) Keep in dish of warm water pending use.

(2) Provide hot water bottle or other means of keeping the serum warm during administration.

(e) During serum administration stand by the patient to

(1) Prevent sudden motion. Patient will often lapse into fitful sleep during serum administration and awaken with start or with coughing spell.

(2) Keep constant close observation of patient's pulse. Report quietly to physician a sudden increase in rate or change in quality. This may be the first indication of a reaction.

(3) Observe patient's color and quality of breathing and report any significant changes.

C *Serum reactions* Doctor's orders for emergency treatment should be obtained in advance. Warm blankets and hot water bottles should be available.

1 Acute anaphylactic (very rare)

(a) If they occur they will usually take place within a few minutes, or before the physician has left the case.

(b) If reactions occur in the absence of the physician, the following emergency treatment should be given:

(1) Administer epinephrine (adrenalin) solution 1-1,000, intramuscularly at once $\frac{1}{2}$ to 1 cc according to severity of reaction. Rubbing and massaging the site of injection will hasten absorption and the desired therapeutic effect.

(2) Send for the physician.

2 Thermal.

(a) Mild reactions of this sort occur in about 5 to 10 per cent of cases. Most frequently they commence in from one half to one hour after serum treatment.

(b) These reactions are not anaphylactic and are seldom serious though always alarming to patient. Epinephrine (adrenalin) is not indicated.

(c) Chill should be treated as outlined in Section III.

(d) Physician should be notified at once.

(e) During subsequent febrile period temperature should be taken every 15 minutes and not allowed to go appreciably above 106° F. It is well to obtain orders for treatment of hyperpyrexia from physician before he leaves.

3 Delayed serum sickness

(a) Patient and family should be reassured.

(b) Symptoms are usually amenable to medication though urticaria may be distressing in severe cases.

(c) Various lotions and external medications may be prescribed.

VII Oxygen Treatment

Medical Aspects

A Indications

1 Anoxemia (reduced oxygen content of the blood) may result from

(a) Respiratory embarrassment due to

(1) Severe pleurisy

(2) Abdominal distention

(3) Accumulation of moisture or consolidation within the lung, which reduces area of functioning alveoli.

- (b) Temporary occlusion of the bronchial passages with mucus
- (c) Circulatory embarrassment

B Objective manifestations indicating oxygen therapy are

- 1 Cyanosis
- 2 Dyspnea with very rapid pulse
- 3 Restlessness and delirium

C Methods of oxygen administration

- 1 Oxygen chamber
- 2 Oxygen tent
- 3 Open top oxygen box
- 4 Nasal catheter or cannula
- 5 Funnel and face masks are unsatisfactory

D Once started, oxygen therapy should not be interrupted until the cause of anoxemia is permanently relieved, except for the shortest possible periods

Nursing Aspects

A Nursing technique 1 A patient receiving oxygen therapy must be constantly watched by a responsible individual

2 Specific detailed information regarding operation and care of the apparatus must be secured. If a tent is used, it should be well tucked in around the patient.

3 If nasal catheters or cannulae are used, the following directions should be observed

(a) Nasal catheters Employ No 10 to No 14 French. Cut off end and make additional openings in the sides. Be careful to smooth edges to avoid irritation. Boil catheters five minutes before use. Moisten about 4 inches with water or mineral oil and insert the catheter gently through the external nares and horizontally along the nasal cavity. When the tip touches the posterior wall of the nasopharynx withdraw the catheter slightly. Fasten it with narrow strips of adhesive tape just back of the nostril and at the temple. Fasten the rubber tubing in place. Two catheters may be employed one in each nostril or one catheter alone if one side of the nose is obstructed or sore. Clean the catheters as often as is necessary to keep them free from obstruction

(b) Metal cannulae Strap to the forehead so that the curved tips of the tubes are just inside the nostrils

(c) Keep the oxygen flow running at the specified volume usually between 3 to 5 liters per minute

4 All oxygen tents, chambers, and boxes of efficient design have cooling units. These will require attention. The optimum temperature range within the tent is 60°-64° F

5 Regulation of oxygen flow No oxygen apparatus, other than the nasal catheter or tube, can be reasonably or even safely run without regularly spaced analysis of the oxygen content and appropriate regulation of oxygen flow. The method of making such analysis can readily be learned by the nurse or an intelligent attendant.

6 Prevention of fire and explosion.

(a) The use of oxygen is always accompanied by danger of fire and violent explosion unless proper precautions are observed.

(b) The following articles should be kept out of the oxygen room and away from all oxygen apparatus matches, lighted cigarettes, and other flames, electrical appliances such as heaters, heating pads, and flashlights, inflammable preparations such as alcohol, ether, benzene, vaseline, and mineral oil. With the application of such precautions no apprehension need be felt.

7 If it is necessary to take the patient out of the tent or to stop oxygen administration,

this should be done quickly and the oxygen treatment should be resumed without delay

VIII Convalescence

Medical Aspects

A Period of complete bed rest

1 It is generally thought advisable to continue this period for at least a week after the temperature has reached normal

B Period of progressive return to activity

1 This is usually started by allowing the patient to sit up in bed for intervals of progressive duration then to use the wheel chair and the bathroom so that he may gradually return to normal activity

C Diet

1 Is usually high caloric and semisolid or solid during duration of complete bed rest

2 Progresses rapidly to normal diet with patient's return to activity

Nursing Aspects

A Period of bed rest 1 It should be remembered that the patient has been through a severe and exhausting illness and the convalescent course must be guided tactfully yet firmly

2 It is often difficult to make patients observe complete bed rest during this interval. Yet too rapid a return to activity will often result in months of comparative disability that could have been avoided by skillful guidance at this point.

IX Complications

Medical Aspects

A Empyema

B Serum sickness

C Septicemia

D Otitis media, acute sinusitis, and mastoiditis, most frequently in children

E Frequent terminal complications

- 1 Pericarditis
- 2 Endocarditis
- 3 Meningitis
- 4 Pulmonary edema

F Other rare complications

- 1 Pneumococcus arthritis
- 2 Thrombophlebitis
- 3 Peritonitis
- 4 Lung abscess
- 5 Acute nephritis

Nursing Aspects

A Empyema Nurse should report such symptoms as elevated temperature, lassitude, failure of appetite to return, night sweats, and localized tenderness over chest

B Serum sickness Nurse should report first evidence of low grade fever, joint stiffness and pain, urticaria, or swollen, tender glands

D Otitis media, mastoiditis, etc Discharging ear, earache, mastoid tenderness should be noted by an observant nurse and reported

E Meningitis Stiffness in neck, if noted, should be reported at once

F Other complications 1 Nurse, by reason of constant attention, morning bath, etc., often is in position to make the first observations

2 Thrombophlebitis This, when it occurs,

is most frequent in the femoral region. Redness and pain over veins should always be noted and reported at once. Such areas should not be rubbed or massaged but should be kept absolutely quiet and protected from trauma.

X Prognosis

Medical Aspects

Certain factors are recognized as materially altering the outlook in any given case. These are:

A Age, the outlook being more unfavorable at the extremes of life.

B Virulence of the micro-organism causing the infection.

C The presence of bacteremia, unfavorable.

D The duration of the disease before specific treatment is instituted, the shorter the interval the better the prognosis.

E The presence of cardiovascular or other chronic debilitating disease, adds an additional hazard.

F Leukocyte response, an inadequate reaction being a very unfavorable sign.

Nursing Aspects

An evaluation of the factors relating to prognosis will aid the nurse in the understanding of her case.

XI Responsibilities

Nursing Aspects

The major responsibilities of the nurse with respect to the problem of pneumonia control are:

A. To be alert in her daily contacts for symptoms suggestive of early pneumonia, and to insist upon adequate and prompt medical consultation in such cases.

B. To disseminate, as far as possible, simple and accurate information to lay contacts with respect to the early recognition and prevention of pneumonia.

C. To do everything within her power to provide the most efficient and adequate nursing care of pneumonia patients in her charge.

Historical Article*

A HISTORY OF MEDICINE IN THE STATE OF NEW YORK AND THE COUNTY OF MONROE

FLORENCE A COOKSLEY, B A , M A , Rochester
Librarian, Rochester Academy of Medicine

Part II History of Medicine in Monroe County

Chapter III

The Early Medical Societies

Organized medicine initiated, Officers and members of County Society, Difficulty of attending State meetings, Early records, Objection to restrictions by citizens Fight against quackery, Stand regarding revision of code of ethics, Change in name of County Society, Formation of other medical societies Rochester Medical Society 1866-1881 New germ theory discussed, Typhoid in Eighth Ward Theories of origin Rochester Pathological Society 1871 to date Formed for dissection, Requirements for admission Scientific papers and social side Public health problems Made section of Academy

County Medical Societies have existed in most of the counties of New York State since 1806 Ontario County, which included Monroe County before 1821, organized a county society in 1806, in conformity with the state law of that year This county, like Monroe County, lost its early records by fire, so that little is known regarding its early meetings In 1821, when Monroe County was formed, a County Medical Society was soon organized, an evidence of the prompt action of which the Rochester physicians were capable. It is unfortunate that we are dependent upon odd sources for information concerning the early activities of the Society, information which is quite incomplete.

The first meeting on May 9, 1821, was announced in the newspaper of April 3, 1821, notice being given to all physicians and surgeons residing in the County of Monroe that a meeting would be held on the second Wednesday of May at ten o'clock in the morning at the home of John G Christopher in the village of Rochester for the purpose of forming a Medical Society according to the law of the State. At that meeting Dr Alexander Kelsey was chosen chairman and Dr John B Elwood secretary Credentials of the following were approved Joseph Loomas, Nathaniel Rowell, James Scott, Allen Almy, Daniel Durfee, Daniel Weston, Isaac Chichester, Alexander Kelsey, John Cobb, Jr, John C Vought, Chauncey Bradle, Theophilus Randall, Frederick F

Backus, M D, and Ebenezer Harmon We note that but one of the above had a medical degree. Election of the following officers then took place president, Dr Alexander Kelsey, vice-president, Dr N Rowell, treasurer, Dr Anson Coleman, secretary, Dr John B Elwood Censors elected were Drs Freeman Edson, John B Elwood, Frederick Backus, Ezekiel Harmon, and Derrick Knickerbocker Nothing further is mentioned in the paper of this society until the annual meeting in May of the next year when the officers elected were, president, Frederick Backus, vice-president, Janna Holton, secretary, William H Morgan, treasurer, Anson Colman, censors, John B Elwood, John Cobb, Jr, George Marvin, M D, Linus Stevens, and Anson Colman Credentials had been received that year from the following Anson Colman, William H Morgan, M D, B Gillette, James Holton, Ezra Strong, William Gildersleeve, Linus Stevens, George Marvin, M D, John B Elwood, O E Gibbs and Barzillai Bush, M D Again we note the few with a medical degree These few with degrees were graduates of medical schools while the rest were licensees of the County Society, who had received their training as apprentices of other practitioners

That county societies functioned early as judiciary bodies is evidenced by a quotation in the very early newspapers, of action taken by the society at Buffalo to expel from the Genesee County Society a Doctor Oren Lee of Bergen for malpractice. This was one of the rights given the county societies

* Continued from our December 1 issue.

by the state law and one of their particular duties

The members of Monroe County Medical Society seldom attended the meetings of the State Society in Albany. An old account book of Monroe County Society records an item of \$15 00 paid as the expense of Dr Backus in attending the meeting in 1829 and a \$45 00 expense of the delegate, Dr A G Smith in attending the one in 1832. Few of the State proceedings mention either delegates from this county or contributions from its treasury. We feel sure from our reading that this was not from disinterest nor neglect but was occasioned by the considerable expense and the tediousness of travel as well as the time required for the trip. The practitioner of those days covered a wide territory in his visits to his patients, just as physicians in isolated districts do today but with this difference, that travel had to be done on horseback or by horse and buggy over bad roads made almost impassable in winter. As always, sickness was increased in the winter months and the State Society session was held in February, one of the worst months for a physician to leave his patients. President Wey of the State Society said at the State meeting in 1872

At its organization and for many years thereafter this Society was limited in membership. Attendance at its sessions were confined to members and delegates living in the near neighborhood of Albany. The season of the year and the difficulty of travel rendered it impossible for members of the profession residing fifty to one hundred miles from the capitol to be present at the annual meetings. Physicians in the northern, western, and southwestern limits of the States were as distant in time from Albany in midwinter, during the first twenty-five or thirty years of the existence of this Society, as we are now from the Western territories.

The treasurer's book of the Monroe County Medical Society fortunately was not in the fire that destroyed the early secretary's book and from it we get some understanding of the financial history of the Society. The membership fee was \$1 25 but no regular dues were charged. At each annual meeting a tax was voted based upon the financial needs of the organization, ranging from fifty cents to a maximum of two dollars. This account book, small as it is, contains the accounts from 1829 to 1874. Conover states that the early minute book was lost but that records from 1842 exist, however,

there is no present trace of this book. We read in the early newspapers of various meetings of the Society, for example, notice of an annual meeting to be held on Wednesday, May 14, 1823 at eleven in the morning at J C Christopher's and signed by the secretary, O E. Gibbs.

The earliest minute book which has remained begins with the stated meeting of June 9, 1875. The society held but one regular meeting a year, with any number of special meetings, usually two to four, held during the year for the transaction of necessary business but generally for the purpose of passing resolutions upon the death of a member. The annual meetings for years, were all-day sessions and were held for some time in the Common Council Chambers of the Court House, the members going outside for the annual dinner. Most of the day was given to reading scientific papers prepared by the members followed by serious discussion. Many of these well-prepared papers are recorded in the minutes and give considerable information regarding medical and surgical practice of the time.

There was considerable discussion in 1876 of the application of the metric system to prescription writing and it was thought desirable that all physicians should familiarize themselves with the system with a view to adopting it later.

As we have seen in reviewing the history of the State Medical Society, the right of the County Societies to prevent the illegal practice of medicine and to bring the offenders to the court for punishment, was misunderstood by the citizens whom the medical profession was trying to protect. In the *Rochester Advertiser* of 1830 we read

A county meeting has been held in the Court House, of which Col Rawson Harmon of Wheatland was chairman and Col A W Riley, secretary, to petition the Legislature for the repeal of the act for the "regulation of physic and surgery." It will be remembered that a person was fined fifty dollars and imprisoned thirty days and another indicted for practicing contrary to the provisions of the statute. The meeting considered the protection granted by this act to regulate physicians "unconstitutional as creating a monopoly," etc. The address issued by it asks, "Have not other societies an equal claim for protection as the Medical Society? If it be constitutional to grant protection to societies or professions, the clergy of the most popular denominations, have stronger grounds for this claim than the doctors of physick, seeing that the health of the soul is

of more consequence than that of the body, and they have also spent their time and money in learning Divinity in the Theological Seminary and have as just a right to protection from those preachers who have not so studied, as the Medical Society have to be protected from a few root and steam doctors scattered over the country" This is the substance of their address and indicates clearly enough their ground of action. The reader can judge for himself.

Three months later, in April, that same paper contained a long account of the trial of a steam doctor in Philadelphia who steamed a child to death and who was found guilty of a misdemeanor. No objection is made this time to the verdict.

The following article quoted from a Lynchburg, Virginia newspaper by the *Rochester Advertiser* in January 1831, was said to be an authentic advertisement of a so-called doctor in Illinois. We may believe or be skeptical as we please, at least it is interesting, coming from that time. The advertisement quoted reads

In offering of my servics to my fello citizens as a publik sarvant, I wuld putricularly remark that I has fur these last nine munnth past, pade the most strictest cares and attentions to the study of physick and I do hope that my natral turn and abilities together with the most closest observation will intitle me to the publik confidence. It wuld be rong in me to purtend to any high larning for you all know that I never rubbid my cote against these collidge walls, nor superintended any of these United States lektur's for lite and knowledge and phosocal docterns. But I hope there will be no objection to me. There is a great deal of the collige felloes that nose no more about an Epidemick oppuration than a three yere old colt and if you was to send wurd for one to cum and see a pursun flat on his back with Apilexy, they wuld no doute give him cold water, which you welkk noe wuld produce an instaneous evacuation of the bowels. My medesons is Simples, consisting of horehoun, ambeer, gypsum weeds and grean gorn seeds, burdok, tanza, grean snake root and mullin—and many other plants of the same kimmical nator. I have a good deal of pations a waittin on me and if you just only give me a call I wuld even git up nite ur day fur to sarve. Your sarvant, Doctur Pea

Whether this be the boasting of an ignorant person or the ironical writing of a disgruntled or disgusted practitioner, it sheds some light upon the misunderstanding then prevalent. For the same reason, let us include another article published in that paper the same year. It was written by an

unsigned subscriber after reading an article telling of the treatment by a quack, of a man and his son ill with scarlet fever. Whether it was written by a layman or by an indignant physician, each must decide for himself. It reads

It has always seemed strange and very surprising that these vultures are suffered to "steam, sweat and labeliaize" their patients to death in as Christian land as ours is, with impunity, and how these men came to institute themselves into the good graces of our law makers so far, as to have their trade or calling partially legalized, has often been enquired.

It is true that there are a great many good root and herbs in our country which are of singular efficacy when used under the prescription of skillful practitioners and there are a great many respectable old ladies who are competent and safe practitioners in the herb line. But there that course should stop.

The law should not allow every lazy drone in the country, who can muster a dollar to purchase one of Thompson's death warrants, to ravage the country with his pepper potions and lobelia pukes and Nos 1 to 6 of the henbane trash. The Law should not allow them to practice, admitting that it does not provide for collecting their bills. We have, too, quite enough of those who have pretensions to practice by virtue of their diplomas, to need a recruited force from the hedges.

A Thompsonian lecturer will engage to qualify a man to practice in his own family and give him a book and medicine for a year for about \$20 00. Now this is attractive, a farmer, for instance, reasons within himself thus: now here I get the science of medicine itself and printed directions, all for \$20 00, next year I shall have only to buy a small stock of medicine, or collect it myself, so I can get along next year with only a trifling charge, where as a single bill from a regular physician should equal all my expenses for two years.

The Steam Doctors admit that they may destroy life in their practice but, they say, the Mercury Doctors kill ten to our one.

During the early settlement of this country, it is true that Mercury under its various forms, was a principle material in the physician's saddle-bags. But at this day, its indiscriminate use is not so very much, since the beginning of the present century.

We certainly do not object against the use of herbs, if the study of the nature and the use of herbs does not belong to the duties, or the course of the Regular Medical Students, we have no doubt but that most of the best read students understand the nature of the application of the powerful qualities of some plants in the vegetable kingdom. It is not therefore, against the herb student or the herb practitioner,

that we would inveigh, it is against Quacks and ignoramuses, who only know just enough to destroy the life of every patient who is so unfortunate as to come into their hands.

Again we say, we feel justified in quoting such articles as these in this record, because we are not only giving historical facts regarding the development of medicine and medical societies in this region but we are also trying to portray trends in public thinking regarding the practice of medicine and showing its influence upon the development of public health laws. We realize the danger of too much dependence upon newspaper accounts for historical material. Frequently facts are distorted or elaborated upon to add interest and color. We will include some of them for the same reason and leave it to the reader to sift the truth in the newspapers, we cannot omit except records. As has been stated, many of the old books of the medical societies have been lost and we must obtain information wherever it is available and trust that most of it is fairly accurate.

Returning to the discussion of the power of the County Societies, we find that Monroe County Medical Society concerned itself not only with the licensing of practitioners but extended its jurisdiction to the practice of midwifery and in 1878 the Board of Censors reported at the annual meeting that eighteen candidates in midwifery had been examined by the Board and eleven had been given certificates to practice. Five dollars was demanded for each diploma but only twenty-two dollars had been collected. In 1881 a special committee appointed to enforce the new state law reported that two arrests had been made for illegal practice but it was not until 1890 that a decided stand was taken against quackery and a committee appointed to make investigations of illegal practice in the city, reported at the annual meeting that they had been unable to bring about any convictions because patients previously treated by the unlicensed practitioners had refused to commit their statements to writing. In 1894 the Committee on Quackery reported that the revision of the law of 1890 in 1893 made it easier to regulate the practice of medicine in New York State and also that a local law required all midwives to register. As the State law now recognized the Homeopathic and Eclectic Societies, the County Society

passed a resolution that its committee on quackery act with local Homeopathic and Eclectic Societies to prosecute violators of the laws regulating the practice of medicine. The following year the Committee reported that the three societies were cooperating and had done a big job in listing all practicing physicians and checking to see if all were licensed to practice. They found that 279 had registered and forty-seven had not, but a few had complied with the regulation since. Several of the offenders had been arrested by the District Attorney and found guilty, while some others had left the city. Examples of quackery in Rochester were cited as "so-called magnetic healers, faith curists, natural bone-setters, lady magnetists who treat men only, electro-therapeutists who treat women in various stages of amenorrhea, pregnant or non-pregnant, visit will call each day and pray for knitting of broken bone or relief of pain in pneumonia, etc." The Society appropriated twenty-five dollars for the expenses of the Committee.

In 1897, an appropriation of \$100.00 was made to further the work of the Committee on Illegal Practice which must have been well used for the following year the Committee reported that the town was being purged of quacks, and the next year the Committee asked to be dismissed as no further progress had been made. We do not hear of this Committee again until 1902 when it stated that an attempt had been made to get an indictment against a certain man and had failed.

Let us consider now the code of ethics and its effect upon the practitioners and upon organized society. We discussed earlier the repealing of the old code of ethics by the State Society in 1884. There was a discussion of the code at the annual meeting of the County Society in 1882 and the members voted for abrogation of the code upon motion made by Dr. William S. Ely but it was by no means an unanimous vote, for fifteen voted for repeal and ten against. The code had been discussed at the special meeting in 1876 and Dr. Jonas Jones at that time stated that while he agreed with the code of the American Medical Association, yet he thought it right to publish in the newspapers the fact that a physician had removed his office or that he had been called to attend an accident case. Dr. Mon-

roe remarked then that the code of that day was more arbitrary than it had been fifty years earlier. That discord regarding the old code existed in the County Society as it did in the State Society, is evidenced by the address given by the President of the County Society, Dr E. M. Moore when he said that he had intended to give a history of the Monroe County Medical Society but would not do so as "this would lead him to say something about the disreputable position the society now held and he desired to avoid this" and he therefore changed his topic to "Is medicine a science?" We regret that Dr Moore did not give the intended history for he might have recorded much that is not now available. This same Rochester physician at the time of the big disagreement in the State Society regarding the code, advised further consideration before serious steps were taken. Those who were planning resignation from the old State Society and formation of a new organization, paid honor to Dr Moore for his words of caution but felt that the old Society was adamant and nothing was to be gained by waiting.

In 1906 the New York State Medical Association and the Medical Society of the State of New York, as we have told earlier, adjusted their differences, and became one body. In May 1903, the Monroe County Society passed a resolution favoring this union and Dr J. R. Murphy stated that "while the national profession had lost much in the past twenty years in the absence of the New York profession, the New York profession had lost much of its prestige because of the unfortunate rupture and strongly urged the profession in the New York State Society to come in, now that the American Medical Association had let down the bars." At the annual meeting the following year the County Society ratified the agreement for consolidation of the two state societies. The name of the Monroe County Medical Society was changed to that of the Medical Society of the County of Monroe in agreement with the new State Society requirement and the first meeting of the reorganized County Society was held on February 28, 1908 and a new election of officers was held, the old officers being re-elected.

In the meantime, other medical societies had been formed in Rochester. The Rochester Medical Society had a brief existence

Formed in 1853 with a short life, it re-organized and endured from 1866 to 1881. The only minute book now remaining is from 1876 to 1881. The constitution printed in 1876 states that the society shall be composed of legally qualified physicians of Rochester and vicinity in good and regular standing who are members of the Monroe County Medical Society and that the Society shall be regulated by the code of ethics of the American Medical Association and by such rules as it shall enact. In September 1876, Dr E. M. Moore, Sr., occupied the entire evening reporting the proceedings of the International Medical Congress which he had attended as a delegate of the American Medical Association. He spoke of the address given by Chief of the Surgical Section, Mr Joseph Lister of Edinburgh, on the subject of antiseptic treatment of wounds. Dr Moore said, "The results claimed by Mr Lister for this treatment were so wonderful as to completely astonish his listeners, old in the profession and teachers of surgery as they were" and, he further remarked, "If no more than half claimed by Mr Lister for this method should prove true, it would still be the greatest contribution made to surgery within the last two hundred years."

All new theories of medicine and surgery were not so enthusiastically received and in that same year (1876) the minutes of the society contain interesting accounts of arguments regarding the new germ theory recently presented. The discussion arose because of an epidemic of typhoid fever in the city, there having been reported fifty cases within four months, all within a small district in the eighth ward. The local Health Officer had investigated and found all of the cases were living within one thousand yards of the corner of Reynolds and Hunter Streets, upon which corner there was located a well used by the afflicted families and that this well was contaminated with surface water. The well was ordered closed and Hemlock Lake water supplied. Two hundred nineteen individuals in forty families had used the well. Dr Stoddard believed that a specific poison was the exciting cause of typhoid fever and that "this poison is never spontaneously generated but is continuously generated. Decomposition whether of animal or vegetable matter is not, in itself sufficient for the production of the specific element but in such decomposition,

that we would inveigh, it is against Quacks and ignoramuses, who only know just enough to destroy the life of every patient who is so unfortunate as to come into their hands

Again we say, we feel justified in quoting such articles as these in this record, because we are not only giving historical facts regarding the development of medicine and of medical societies in this region but we are also trying to portray trends in public thinking regarding the practice of medicine and showing its influence upon the development of public health laws. We realize the danger of too much dependence upon newspaper accounts for historical material. Frequently facts are distorted or elaborated upon to add interest and color. We will include some of them for the same reason and leave it to the reader to sift the truth. Where there are no facts recorded except in the newspapers, we cannot omit such records. As has been stated, many of the old books of the medical societies have been lost and we must obtain information wherever it is available and trust that most of it is fairly accurate.

Returning to the discussion of the power of the County Societies, we find that Monroe County Medical Society concerned itself not only with the licensing of practitioners but extended its jurisdiction to the practice of midwifery and in 1878 the Board of Censors reported at the annual meeting that eighteen candidates in midwifery had been examined by the Board and eleven had been given certificates to practice. Number 24]

sent from the meeting that year. It was the time of trouble in the State Society which we have discussed earlier. The minutes of that last meeting end abruptly and are partly on rough paper, not entered into the book. We can presume that the Society there ended *sine die*. Dr. Edward Angell in his chapter in the History of Rochester and Monroe County by Peck, states, "Its membership embraced the more prominent of the city physicians of its time but its very success was the cause of its downfall, its elaborate suppers becoming too great a burden and toward the close of the seventies it faded away."

Let us retrace our steps and go back to the origin of another medical society in Rochester, one that began in 1871 and is still prospering. In the summer of 1871 Dr. John Oakes, Dr. Buckley, and Dr. Udell met at the office of Dr. Oakes at the corner of Main and St. Paul Streets and formed a society known as the Rochester Pathological Society, formed for the purpose of studying dissection. Doctors Roe, Franks, Gallery, Starr, Baker and Weigel were the early members. The society obtained a cadaver and met once or twice a week for work and quizzes, meeting in a room in the same building in which Dr. Oakes had his office and sometimes dissecting in Dr. Starr's barn. Then the city donated a sum of money to the Society for the purpose of founding a dispensary and, as the minutes of 1884 state, "after awhile, the dispensary died from exhaustion, the members of the staff dropping out one by one and leaving no assets but some liabilities." This dispensary will be discussed at length when the smaller organizations of the city are considered.

The meetings of the Pathological Society were held in the homes or offices of members up to 1878 when the Rochester Whist Club was selected as a meeting place. After the meetings adjourned, the society members repaired to nearby restaurants for refreshments. Beyond these facts and that Dr. Udell was first president, we know little of the early history of this medical organization. If there was an early minute book, it disappeared long ago and the first record it begins with the meeting of September 7, 1875, four years after the Society was begun. As stated in the constitution of the organization, its purpose was to "form among the younger members of the profes-

sion a working body who shall meet as often as the by-laws provided, for social intercourse and mutual improvement in the medical and kindred sciences." Through the many years that this Society has functioned, the social side has not been neglected and during most of the years there has been a repast following the meetings and an annual picnic, the latter always serving as a reunion.

At first, meetings were held twice a month with semi-annual meetings and election of officers. Later there was but one annual meeting and officers served for a year. The by-laws of the Society were subjected to repeated changes, dealing mostly with admission to membership. In the early years, membership in Monroe County Society and six years of practice in medicine were required for admission. Later the years of practice clause was revised as it was felt that the Society had much to give the young practitioner and membership should not be denied him. Beginning in 1891, a thesis was required before candidacy for membership was considered. Blackballing rather successfully kept out unpopular candidates but often, too, barred some of the worthy practitioners, when personal feeling was allowed to influence a vote. It was recognized that many desirable medical men were withholding their applications for membership fearing the blackball and the power of election to membership was placed in the hands of the Council, the governing body of the Society. Until then the names of proposed members had been read in open meetings and elected or rejected, without these men having expressed a desire for membership. This was remedied by having written applications received, which rule is still in existence.

It is difficult to follow through all these changes in the by-laws but each was thoughtfully made for the benefit of the individual and of the organization. The Society did a splendid work in those early days, bringing to the members the newest in medical literature and therapeutics. Carefully prepared papers were presented by the members and discussed by a large percentage of the listeners and these discussions were often spirited and lasted until a late hour with no decision reached and the members parting in amiable disagreement. Sometimes the Chair appointed a member to search the literature concerning

the specific element unquestionably finds favorable ground for its growth and multiplication. The poison may retain its vitality even for years. It may enter the system with the air we breathe, or with the water we drink, the latter being the more apt to contain it. If a privy containing the dejections of a typhoid fever patient is located near a well the specific poison may find its way through the soil and thus contaminate the water, or the water in which the bedding or utensils used by the patient may be thrown on the ground and find its way into the well from the surface." The Board of Health had passed a law that spring ordering all wells closed that were located within twenty feet of a privy. The Eighth Ward well mentioned, received surface washings of horse urine and manure and besides, the owner of the well had recently recovered from typhoid and it was suggested that probably his excreta had entered the well.

Dr Montgomery objected to the findings of the Health Officer. He said that the well had been used for many years and there had been no typhoid before and besides, Professor S A Lattimore of the University of Rochester had analyzed the water and found nothing harmful. Dr Montgomery thought that "every human being is born into the world with the germs of certain diseases within him and that no matter what his surroundings, no disease can be produced in him, the germ of or the tendency to, which is not congenital." He expressed his belief that "there is only one way by which we may hope to eradicate disease and prolong the duration of human life and that is by improving the breed."

Dr Hovey said at the same meeting, that there had been sewers dug recently in the vicinity of the well, which caused a poison to be brought to the surface, this poison being the causative agent in production of zymotic disease, and that while he was ignorant of the etiology of typhoid fever, he thought it exists in the atmosphere and enters into the lungs. Just a year later, typhoid was reported again, this time in two adjoining houses on Howell Street near South Street. These two families used the same "appointments" and it was found that the drains led directly to the sewer without curved traps, therefore sewer gas was blamed for the typhoid outbreak. Again Dr Montgomery objected, for he said he knew of a

case of typhoid contracted while in Chicago and this case had infected two others here. He thought that someone from the outside had brought it to the two families on Howell Street and they had infected one another. Dr Whitbeck said he thought the physicians had gotten into a rut and classified as typhoid, typho-malarial or malarial fever, due to a misamata generated in houses through want of cleanliness. He stated further, that typhoid fever occurred rarely after forty to fifty years of age and almost never after sixty.

Again, in 1879, the minutes record that Dr Little read a paper on "Some Lessons from Nature." "He spoke in very disrespectful terms of the germ theory of disease and prophesied that fifty years hence it would be much less thought of than now. He entered a general protest against so-called antiseptic surgery which he characterized as the substitution of one bad smell for another." These observations are by no means unique but they are particularly interesting to us because they occurred here among our own practitioners, men of high repute in the county.

The membership of the Rochester Medical Society, whose minutes we have quoted, was never very large, being less than thirty-five with an average attendance of seventeen but the meetings were at first very interesting and the discussions spirited. In October 1879, a growing luke-warmness at the meetings was discussed. The minutes of that time are meager, so that we do not know whether good papers were lacking or whether the scribe failed to record them. In December of that year the secretary reported an apathy on the part of members and said there must be a renewal of interest or the usefulness of the Society was at an end. At the annual meeting the following December, it was reported that only eight meetings had been held during the year with an average attendance of eleven and that no pathological specimens had been presented through the year. Although there were only twenty-eight regular members and four honorary members, Dr Stoddard objected at the meeting the next month, to adding any new members as the Society was already too large. The last minutes recorded were of the meeting held February 7, 1881. Dr Ely reported the meeting which he had attended in Albany and said it was noticeable that noted men were ab-

small evacuation occurred. "The Society then," the minutes read, "laid itself out to beat Dr Moore's record and several exceedingly constipated stories were presented for its consideration." This meeting of 1884 was held two years before Hirschsprung's disease was first described, so that Dr Moore's report would not be considered with so much amusement today. Dr Dewey closed the discussion that night by speaking of treating impaction in the upper bowel by "the introduction of a tube into the colon and the injection of water as high up as possible." No doubt this method so abused by quacks of today was then used with discretion.

In 1884, Dr Carpenter in his paper on "Fever, a Neurosis," began by taking "a hit at the believers in the germ theory" and then stated that he believed "fever to be due to the disturbance of the equilibrium of the heat centers and that daily variation in temperature in health and disease was caused by the oscillation of the force controlling heat." Dr Farley in response, stated that he saw "no reason for doubting a heat center but the presence of one throws no cold water on the germ theory or any other theory."

The germ theory was an object of attack in this Society almost as frequently as in the Monroe County Medical Society. In 1885 when Dr Edward Angell read a paper on epidemic diseases, he stated that he thought miasmatic diseases such as cholera and typhoid fever were "contagious only through the medium of some germ from an original case which had undergone subsequent change" and Dr Streeter in reply, said, "as far as germs are concerned in the specific nature of these diseases he believed them to be an effect rather than a cause and that as far as surgery is concerned, no practical results had been attained except the greater attention to cleanliness." Then Dr Charles D. Wooden stated his disbelief that germs had any causative relation to disease and added that "his theory of disease" was that "an individual either has or does not have any particular disease according as he may have an innate tendency toward it or be free from susceptibility. He had handled smallpox without being vaccinated and without contracting it." Three years later, in 1888, Dr P. D. Carpenter in his paper on Progress in Medical Science, "ridiculed homeopathy, Christian Science

and the germ theory" and Dr Kempe arose in defense of the germ theory, having been impressed by the antiseptic treatment of wounds. It is soon afterward that we begin to read repeated references to the germ theory in these minutes, just as though its truth had never been questioned.

Dr Dewey, in 1889, read an inspiring paper on Physical Immortality in which he said that there are three periods in animal life—growth, decline, and an indefinite period between—and that "when we learn to live according to natural laws and the adjustment of our internal relation to our environment becomes as nearly perfect as the inevitable progressive changes in our organism will admit, then we may expect lives of greater length, of increased comfort and enjoyment of enlarged activities and capabilities with decline painless and slow. We can never attain physical immortality but may attain patriarchal length of days and fulness of strength."

Let us not be misunderstood in reading these abstracts of early medical papers read by the members of the Pathological Society. Many of the papers, in fact most of them, were prepared with care and great seriousness and all were earnestly striving to attain knowledge in the art of medicine. Sometimes it is hard today to believe that certain known facts were but theories a few years ago and unaccepted by many. One of the speakers at a meeting said that he did not value the contents of medical books more than ten years old and the medical readers of today rarely consult books more than five years old. Yet in reading these papers, we are not surprised at the great change in the practice of medicine but rather that so many things which were written in those days are still recognized as applicable now.

The Pathological Society until its amalgamation with the Rochester Academy of Medicine, considered it an obligation to advise in matters of public health and frequently made resolutions instructing city, county, and State in matters pertaining thereto. It kept a watchful eye upon laws about to be enacted and took action upon them. It made suggestions regarding the health of the child in school, proposed places where State and County institutions should be built, regulation of the practice of nursing, in fact, the Pathological Society functioned in regard to public health matters

the disputed subject and to report at the following session. Pathological specimens were inspected with interest and microscopic examinations ordered with a report to be made at the next meeting. Occasionally these specimens were abnormal fetuses, such as that shown in 1890 by Dr Herriman, a seven months fetus with lower limbs coalesced into one, the soft parts of the legs being perfectly joined together although the femora were separate, the fetus also lacked sexual organs and an anus. Then in 1911, Dr F A Jones exhibited a three and one-half months old fetus with closed abdominal walls with the heart, liver, and intestines outside, and also having clubbed hands and feet. Also, there were living freaks, such as the glass eater who attended a meeting in 1887 and demonstrated his ability to swallow broken glass without cutting his mouth or throat and apparently without harm to his digestive tract, and in 1894, a Sam Harrison cheerfully swallowed tacks, knife blades, shingle nails, and other such objects for the entertainment of the medical men. A few years later another would-be demonstrator of that sort was refused admission.

For many years there were no dues in the Pathological Society but an assessment was voted whenever there was a need of funds. This tax was fifty cents at first, then increased to one dollar and for many years varied from one to two dollars, finally being increased to three and even five dollars. With increased growth of the Society came multiplied activities and the need for rented quarters, causing an increase in expenditures. In 1883, the membership had grown to fifty-four and it was thought by many that a limit of sixty should be made and only those admitted who had shown superior ability but after long discussion, it was voted not to limit the numbers. As Dr Wilbur expressed it, limitation was selfishness and "if the Pathological Society is a good thing, for God's sake give every young man a chance at it."

This Medical Society differed from other similar societies of the city in having its social side. When the organization was small, a member would act as host, having the meeting at his office, and afterward serving a lunch there or taking the members to a nearby cafe or hotel. Many amusing references were made in the minutes to these repasts, as in 1882, "several motions

were made and seconded by all present and the question of final disposition of coffee and oysters was settled without a dissenting voice," and in the following year, after a discussion of postmortem examinations, "after some discussion, the Society proceeded to investigate the cause of death of numerous oysters, which were found to be stewed." Again in 1884, after arguing the merits of alimentation versus medication in the treatment of typhoid fever, "the Society adjourned and accepted Dr Dewey's invitation to Teall's where all were thoroughly convinced that alimentation was far preferable to medication."

Many of the minutes of regular meetings report in considerable detail the paper of the evening and the discussion which followed. Some of them show the change in medical practice since that time and may be sufficiently interesting to quote here while others because of their unusualness may also be of interest. In December 1878, Dr Buckley addressed the Society reporting what he had seen of the yellow fever epidemic which had recently raged in the South. He said the assistance and sympathy from the North had done more to cement the ties of friendship between the two areas than any other circumstance in the whole world could have and, he added, "perhaps a wise act of Providence thus showed the South the love of the North for them at this day." In 1883, the same physician, Dr Buckley, exhibited a specimen of an ovarian tumor and said he had been able to obtain the specimen by explaining to the relatives of the woman that it was *not* a part of the patient's body but a pathological growth and "when they understood all of the person was to be left for burial and nothing taken that *properly* belonged to her body, they made no further objection to the physician's taking away the tumor."

Evidently some of the remarks reported in the minutes are not intended to be taken seriously but we have to judge for ourselves when a smile accompanied the remark. In 1884, after a paper by Dr Darrow on intestinal obstruction, Dr Moore reported a case of a woman "whose bowels acted but once in twenty days and then passed but a small quantity," no injury then occurring, the period became thirty day and purgatives and an enema every night of a pint of water were ineffective, the enemata being retained until the thirtieth night, when a

MATERNAL WELFARE

The Public Health Council of the State of New York on November 20 adopted a revision of the State Sanitary Code in connection with Maternity Hospitals and

Homes and their supervision by the State Department of Health

For the information of all physicians the code, as revised, is here reproduced

State Sanitary Code

CHAPTER XII

Section A—Maternity Hospitals or Homes

Regulation 1 Definition Any hospital or home which is not incorporated and into which women not related to the proprietor or person in charge by blood or marriage are received to be cared for during pregnancy, during parturition, or while recovering from parturition, shall be considered a maternity hospital or home

Each maternity hospital or home shall have a name, which name shall appear on the license form and on all certificates of birth and death occurring in the hospital or home.

Regulation 2 License and inspection Each maternity hospital or home shall, before the admission of any patient, obtain annually from the state commissioner of health a license to conduct and maintain such a hospital or home. On and after December 1, 1936, no license for the conduct of a maternity hospital or home shall be issued to any person unless he or she is a physician or midwife licensed to practice in the state of New York, or a registered nurse registered in the state of New York, except that this shall not apply to proprietors licensed previous to December 1, 1936. On and after December 1, 1936, every proprietor of a maternity hospital or home, not a physician or midwife licensed in the state of New York, or a registered nurse registered in the state of New York, if maintaining an establishment with a capacity of four or more beds, shall employ a nurse so registered to give full time attention to maternity patients while they are under care in such maternity hospital or home.

No license shall be issued by the state commissioner of health to any person to maintain a maternity hospital or home unless the commissioner or his duly authorized agent shall have made an inspection of the premises. A record of each such inspection shall be made on a form prescribed by the state commissioner of health and such record shall be filed in his office

In each maternity hospital or home the license shall be kept posted by the licensee in a conspicuous place

Each license for a maternity hospital or home shall state the maximum number of beds which are provided and reserved for maternity patients only and no more maternity patients than that number shall be cared for at any one time. The capacity as stated in the license shall not exceed the number of beds so reserved.

Every proprietor of a maternity hospital or home shall maintain a register containing the names and addresses of all maternity patients cared for and such other information as may be required by the state commissioner of health or by section four hundred eighty-two of the penal law and section three hundred three of the state charities law

If the maternity service for which such license was issued be discontinued, or if the license expire or be revoked, such license shall be returned immediately to the state department of health, together with all registers

Regulation 3 General requirements In maternity hospitals or homes each patient shall have and occupy a separate bed located in a room adequately ventilated and providing at least eighty square feet of floor space for each bed.

In any maternity hospital or home in which there are rooms accommodating more than one patient, the beds shall be separated by spaces at least three feet in width, a separate adequately ventilated room shall be provided exclusively for newborn infants, with one crib for each infant.

In a maternity hospital or home with a capacity of four or more patients, a delivery room which shall be used for no other purpose, shall be provided and maintained, separate and distinct from the bedrooms and from any operating room used for general hospital service. The delivery room shall be equipped with running water and

just as the County Societies do today and as they tried to do then, less effectively though because of their infrequent meetings.

Mention has just been made of the amalgamation of the Pathological Society and the Academy of Medicine. The proposal for uniting the two societies appears without warning in the minutes of the Pathological Society, but it had been discussed for some time by the Council. In October 1908, an entire evening was given to the question of amalgamation and it was decided to canvass the membership to get the general opinion concerning it. On November 27, that year, the president stated that seventy-six postcard ballots had been received, sixty-five voting for and eleven against and the amendment was declared carried. Those who opposed the affiliation were not lukewarm in their opposition and did everything within their power to prevent such action. On February 18, 1909, a

determined effort was made by a few members to have the amendment rescinded and the vote was ten to fourteen against. One member in desperation threatened to apply to the court for an injunction restraining the Society from amalgamating. Evidently he forgot his displeasure for we soon find him as active in the Society as ever.

Except that the Pathological Society was now a section of the Academy of Medicine, there was not a great deal of difference in its function for some time. Gradually, outside speakers were dispensed with and the Society no longer took action upon civic and State affairs. Before discussing the work of this Society further, we shall consider the origin of the Academy of Medicine and the events which led to its organization.

(To be concluded in the next issue)

MISCHIEVOUS IMAGINATIONS

As the New York papers report it, some three hundred children's specialists had a merry and perhaps informative time on Nov 12 listening to some of their colleagues speak harshly of medical jargon and rip into doting mothers, spoiled infants and Freudian dilettantes in plain, every-day words.

The round-table fireworks, conducted at the New York Academy of Medicine, were ignited by a paper read by Dr Leo Kanner, of the Johns Hopkins School of Medicine, who remarked that a child is often the parents' hypochondriac organ.

Invalid reactions, he remarked, were found in persons of all ages, often being substitutes for thwarted ambitions, failure in love and unhappiness in marriage. These reactions, he said, included imaginary headaches, stomachaches, heartaches and other pains "demanding no end of consideration and commiseration" on the part of families, friends, doctor and druggist.

Most cases in childhood, he went on, came from the ranks of the pampered. He cited the boy who had a cramp in the arm during arithmetic lessons only, and several children who were violently ill only from Monday through Friday, with full parental en-

couragement. Jabbing at the technical terms employed by the followers of Freud, Dr Kanner advocated elimination from the language of such terms as neurosis, prenatal influence, inferiority complex and mother fixation. He also would ditch talk of a person having "a touch" of this or being "on the verge" of that.

Continuing the discussion of over-indulgent parents who artificially retard self-dependence in their children, Dr William S Langford, of the pediatric clinic at Babies Hospital, said there was such a thing as a mother having a real need for a child to be sick. Dr Herbert B Wilcox suggested that perhaps the thing hypochondriac children need most is scientific neglect.

Dr Ira S Wile, mentioning the "illness" which the offspring of over-indulgent parents develop after an appendectomy or a tonsilectomy, was of the opinion that perhaps the only cure might be a "parentectomy." Discussing pampered youngsters, he told one of his parents who said to him, "if you don't get a toy I'll have a vomiting spell, and the child selected, as the setting, no less prominent a corner than that of Fifth Avenue and 42nd street.

MATERNAL WELFARE

The Public Health Council of the State of New York on November 20 adopted a revision of the State Sanitary Code in connection with Maternity Hospitals and

Homes and their supervision by the State Department of Health

For the information of all physicians the code, as revised, is here reproduced

State Sanitary Code

CHAPTER XII

Section A—Maternity Hospitals or Homes

Regulation 1 Definition Any hospital or home which is not incorporated and into which women not related to the proprietor or person in charge by blood or marriage are received to be cared for during pregnancy, during parturition, or while recovering from parturition, shall be considered a maternity hospital or home.

Each maternity hospital or home shall have a name, which name shall appear on the license form and on all certificates of birth and death occurring in the hospital or home.

Regulation 2 License and inspection Each maternity hospital or home shall, before the admission of any patient, obtain annually from the state commissioner of health a license to conduct and maintain such a hospital or home. On and after December 1, 1936, no license for the conduct of a maternity hospital or home shall be issued to any person unless he or she is a physician or midwife licensed to practice in the state of New York, or a registered nurse registered in the state of New York, except that this shall not apply to proprietors licensed previous to December 1, 1936. On and after December 1, 1936, every proprietor of a maternity hospital or home, not a physician or midwife licensed in the state of New York, or a registered nurse registered in the state of New York, if maintaining an establishment with a capacity of four or more beds, shall employ a nurse so registered to give full time attention to maternity patients while they are under care in such maternity hospital or home.

No license shall be issued by the state commissioner of health to any person to maintain a maternity hospital or home unless the commissioner or his duly authorized agent shall have made an inspection of the premises. A record of each such inspection shall be made on a form prescribed by the state commissioner of health and such record shall be filed in his office.

In each maternity hospital or home the license shall be kept posted by the licensee in a conspicuous place.

Each license for a maternity hospital or home shall state the maximum number of beds which are provided and reserved for maternity patients only and no more maternity patients than that number shall be cared for at any one time. The capacity, as stated in the license shall not exceed the number of beds so reserved.

Every proprietor of a maternity hospital or home shall maintain a register containing the names and addresses of all maternity patients cared for and such other information as may be required by the state commissioner of health or by section four hundred eighty-two of the penal law and section three hundred three of the state charities law.

If the maternity service for which such license was issued be discontinued, or if the license expire or be revoked, such license shall be returned immediately to the state department of health, together with all registers.

Regulation 3 General requirements In maternity hospitals or homes each patient shall have and occupy a separate bed located in a room adequately ventilated and providing at least eighty square feet of floor space for each bed.

In any maternity hospital or home in which there are rooms accommodating more than one patient, the beds shall be separated by spaces at least three feet in width, a separate adequately ventilated room shall be provided exclusively for newborn infants, with one crib for each infant.

In a maternity hospital or home with a capacity of four or more patients, a delivery room which shall be used for no other purpose, shall be provided and maintained, separate and distinct from the bedrooms and from any operating room used for general hospital service. The delivery room shall be equipped with running water and

furnished with such minimum equipment as may be prescribed by the state commissioner of health. Except with the permission of the state commissioner of health such delivery room shall be located on the same floor as that on which the maternity patients are cared for.

Where general hospital service is given, the bedrooms for maternity patients and for newborn infants and the delivery rooms shall occupy an entire floor, or a separate wing of a floor, reserved exclusively for maternity patients, and the floor or wing so reserved shall not be occupied by other medical or surgical patients.

Every floor in a maternity hospital or home shall be adequately equipped with fire extinguishers approved by the state commissioner of health, and no patient shall be cared for above the first floor unless there is adequate provision approved by the state commissioner of health for safe exit in an emergency, with easy access from patients' rooms in case of fire.

The surfaces of all ceilings, walls and floors and furnishings in delivery rooms and in rooms to be occupied by maternity patients or newborn infants shall be of washable material and such rooms shall be provided with suitable equipment necessary for the care of mothers and infants. Such rooms shall be maintained in a cleanly condition at all times.

Adequate and sanitary bathing and toilet facilities shall be provided for maternity patients and for infants.

All outside doors, windows, and other outside openings shall be screened, except during the winter.

Adequate facilities shall be provided for the sterilization of instruments and water, and for the steam sterilization of supplies.

Each maternity hospital or home shall have at least a minimum of equipment as prescribed by the state commissioner of health.

Regulation 4 Standard procedures. No maternity patient shall be cared for in the same room with a patient not a maternity case and equipment and beds used by maternity patients shall not be used by other persons.

Except in a temporary emergency, no infant shall be cared for in a maternity hospital or home except during the residence of the mother therein, without the approval of the state commissioner of health or his authorized agent.

Every patient in a maternity hospital or home shall be attended during confinement and supervised during the puerperium by a registered physician or a licensed midwife.

The advantages of breastfeeding shall be explained and emphasized to the mother by the physician or midwife in attendance and artificial feeding shall not be resorted to except upon a specific written order from a physician.

It shall be the duty of the attending physician, midwife, nurse or other person in attendance on a confinement to drop into both eyes of the infant immediately on delivery a one per cent solution of nitrate of silver or some other agent equally efficient for preventing ophthalmia neonatorum.

Before either mother or infant is taken from the delivery table or bed, a means of identification approved by the state commissioner of health shall be attached to each newborn infant and such means of identification shall not be removed from the infant until discharged from hospital or home.

All drugs and solutions shall be correctly and distinctly labeled and kept in a locked closet when not in use.

A chart shall be kept for each maternity patient and for each newborn infant, which shall show the history of the case, results of examinations, progress of the case and such other data as may be required by the state commissioner of health, and on a form approved by him.

Regulation 5 Communicable disease. No maternity hospital or home, shall accept for care or treatment any patient, not a maternity patient, suffering from influenza, erysipelas, or an infected wound or lesion, or from a communicable disease required to be isolated by the sanitary code. A maternity patient suffering from any such disease may be admitted and cared for in a maternity hospital or home if a separate room with adequate isolation facilities is available and such patient is isolated in such room.

In the event that a case of (communicable) such disease develops in any patient in a maternity hospital or home, the patient shall be isolated in accordance with instructions of the local health officer, and the bed and equipment used for such patient suffering from such disease shall not be used (again) for a maternity patient until they shall have been disinfected in accordance with the instructions of the health officer, and no other patient shall be admitted to the hospital or home until permitted by the health officer.

Regulation 6 Reports. At the end of each calendar year the licensee of an unincorporated maternity hospital or home shall submit to the state commissioner of health a report of maternity cases cared for during the year and such other data and in such

form as may be required by the state commissioner of health

Regulation 7 Revocation For failure to comply with any state or local law, rule or regulation, or for any cause which the state commissioner of health may deem a menace to the health of the patients in the maternity

hospital or home, any license may be suspended and, after due notice and opportunity for hearing has been given, may be revoked

Regulation 8 When to take effect. Every regulation in this chapter, unless otherwise specifically stated, shall take effect on the first day of December, 1936

MEASLES AND SCARLET FEVER

Manhattan Convalescent Serum Laboratory

Convalescent Measles Serum and Convalescent Scarlet Fever Serum are available at the Manhattan Convalescent Serum Laboratory which is located in the Research Laboratory division of the Department of Health, at the foot of East 15th Street This laboratory has the cooperation of the Department of Health, and has been aided by the grant of funds from several foundations

The serum is prepared from blood obtained from adults convalescent from or recently recovered from measles or scarlet fever Since the serum is human serum it does not cause reactions when injected subcutaneously, intramuscularly or intravenously It, also, does not sensitize individuals to subsequent injections

Measles Convalescent Serum should be injected subcutaneously within five days after an individual's exposure to this disease for prevention, or up to the eighth day, to limit the disease to a modified or attenuated form

Scarlet Fever Convalescent Serum is useful in preventing the disease when injected

shortly after exposure. It is particularly useful in treatment when given within the first three days of the disease, and when administered intravenously It, also, has value in treating patients with complications, and whose admission to the hospital has been delayed

Serum is distributed only through physicians for their private patients or to institutions and hospitals

In order to maintain the supply a charge sufficient to cover the cost of production is necessary

Several other types of convalescent serum may be available in the near future.

The new service is under the immediate direction of Dr William Thalheimer, who will be glad to discuss the use of the various sera with physicians who may be interested Address the Manhattan Convalescent Serum Laboratory, Foot of East 15th Street, New York City Telephone, Stuyvesant 9-3100 On weekday evenings and on Saturdays, Sundays, and holidays after 4 P M call Worth 2-6900

MICHIGAN'S 'FILTER SYSTEM'

Considerable attention is being attracted by what is known as the "filter system" in use in Michigan to sift out the worthy from the unworthy who apply for free hospital and medical care There are really two filters, it seems, one medical and the other economic. As described in a western medical journal, the economic filter is composed of the County Judge and two representative business men (not politicians) who investigate the economic status of the applicant. The reason for having the County Judge as a member of the filter is that he has authority to administer oaths and it is possible then to obtain sworn evidence The investigation by these three determine definitely the economic status of the applicant.

The medical filter is composed of the County Health Officer, one Surgeon and

one Eye, Ear, Nose and Throat specialist. This filter determines the necessity of medical care and whether or not the condition is an emergency, demanding hospitalization.

After an applicant is acted upon favorably by these two filters it is a proper case for hospitalization and special care. Should either filter find reason to object to admitting the applicant for hospitalization the case is then dismissed so far as this sort of assistance is concerned.

By the application of this method the medical profession receive the protection they deserve and are not called upon to operate cases where emergency hospitalization is unnecessary, and are not called upon to do work free of charge for people who might be in position at some future time to meet this expense.

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

DR. ANDREW MACFARLANE, seventy-two, the first physician in Albany to use anti-toxin in diphtheria cases, died on Nov 10

Originator and editor for a time of the Nelson Loose Leaf System of Medicine, Dr MacFarlane wrote for various medical journals and publications

Albany's first bacteriological and pathological laboratory was established by him in a room in the old Albany Medical College which stood at the junction of Eagle, Lancaster and Jay Streets

At one time, he was attending physician at the Albany Hospital, St. Peter's Hospital and Memorial Hospital and at the time of his death was consulting physician at St Peter's Hospital During the World War, he was captain in the Medical Corps

Having once served as president, he was active in the affairs of the Albany County Medical Society

Bronx County

THE BRONX COUNTY *Medical Bulletin* notes that "since the enactment of the state compensation law, the value of every medical service rendered has been legally established Provision is made not only for the maximum fee, but also for the minimum fee to be charged for each specific service Therefore, at the present time, we can convert the service rendered by the physician to the general public into actual cash value The Federal and State governments permit a taxpayer to deduct a certain percentage of his income which he donates to charity It then behooves us physicians to demand the same deduction for services donated by us to the city and its citizens We therefore recommend that all hospitals and dispensaries, where physicians render free services, record the number of visits and treatments rendered, in order that we may have a complete knowledge of the actual savings to the city and community through the charitable acts of the medical profession"

INTERESTING PAPERS were presented at the meeting of the Bronx County Medical Society on Nov 18 on "Recent Progress in Diabetic Surgery" by Leland S McKittrick, M D with discussion by Henry Roth, M D, and Thomas O'Kane, M D, and on "Recent Progress in Diabetic Therapy" by Howard

Root, M D, with discussion by Frederick Williams, M D, and Sol. Biloon, M D

Broome County

REGULAR EXAMINATIONS BY the family physician were advocated as the most effective means of detecting and controlling heart afflictions at a meeting of the Broome County Medical Society on Nov 10 at Lourdes Memorial hospital by Dr R. E. Morgan, professor emeritus of clinical medicine at Temple University, Philadelphia

"Cardiac afflictions are among the most frequent causes of death," Dr Morgan pointed out. "Diagnosis and treatment of such conditions are well within the ability of the average doctor at first-hand, without recourse to elaborate instrument studies" There is hope for recovery for many suffering attacks of acute cardiac condition

DR JESSE G N BULLOWA, clinical professor of medicine, New York University Medical College and visiting physician at the Harlem Hospital, spoke on "The Management of Pneumonia" before the Binghamton Academy of Medicine on Nov 10 at the Monday Afternoon club

Chemung County

THE ONE HUNDREDTH ANNIVERSARY of the Chemung County Medical Society was observed at a dinner meeting in the Mark Twain Hotel, Elmira, on Nov 21

From a handful of "country doctors" in the little city on the banks of the Chemung shortly after the new county had been whittled from old Tioga County, the society has grown to include nearly one hundred physicians

To the celebration came officers of medical groups in Steuben, Schuyler, Broome, Tioga, Tompkins, and Cortland Counties and Dr Floyd F Winslow of Rochester, president of the State Medical Association

Dr Arthur W Booth reviewed the history of the Society during its one hundred years

Dr Ross G Loop told of methods and treatments used by the profession during the last one hundred years Dr Anna M Stuart told of women physicians in Chemung County medical history

Dr Reeve B Howland had gathered exhibits connected with medical practice, instruments, and pictures of former physicians

Dutchess County

THE DUTCHESS COUNTY MEDICAL SOCIETY met on Nov 11 at the Amrita club. A nominating committee was appointed to select candidates for offices for the coming year. Dr Frederick W Williams of New York city discussed "Treatment of Diabetes," from the medical standpoint, and the surgical viewpoint was discussed by Dr Thomas J O'Kane of New York city.

Erie County

NOMINATION OF OFFICERS of the Erie County Medical Society and delegates to the state convention for 1937 was held in Hotel Statler on Nov 16.

The nominees are President, Dr John T Donovan, first vice-president, Dr Harry C Guess, second vice-president, Dr Carlton E. Wertz and Dr Mesco J Helmimak, secretary, Dr Louise W Beamus, treasurer, Dr Caryl Koch and Dr William F Jacobs, board of censors, Dr Charles W Bethuna, chairman, Dr Michael A Sullivan, Dr Abram Weil, Dr Francis E Fronczak and Dr Francis J Butlak.

Committee chairmen Legislation, Dr James L Gallagher, public health, Dr Nelson W Strohm and Dr R. H Wilcox, Tonawanda, economics, Dr Joseph C O'Gorman and Dr Harvey P Hoffman, membership, Dr Allen R. Long.

Delegates to the state convention (four highest to the elected, next four highest to be named alternates) Dr Roy L Scott, Dr James H Borrell, Dr Milton G Potter, Dr John Burke, Dr Thurber Lewin, Dr Harry C Guess, Dr J Herbert Donnelly, Dr W Warren Britt, Tonawanda, Dr Robert E. De Ceu, and Dr Mary J Kazmierczak.

A recommendation of the financial survey committee, composed of Dr R. L Scott, Dr James H. Borrell, and Dr Alfred Noehren, that the bylaws of the society be amended to provide for an increase in the membership dues from \$15 to \$18 was adopted.

The report of Dr Frederick W Filsinger as chairman of the health survey committee took the form of an appeal for elimination of politics from the county society.

In this line he recommended that an amendment be made to the constitution "making the cliquing of members and lobbying at election time for political purposes or dominance in the affairs of the society, which is detrimental to the interests of the rest of the membership, punishable by discipline by the society."

He further proposed an amendment that any member of the society who is an em-

ployee of city, county, state or federal government be subject to discipline of the society "if he violates the principles of professional conduct by working against the interest of the members of the society."

Kings County

OFFICERS FOR THE COMING YEAR were nominated at a meeting of the Kings County Medical Society, attended by about 200 on Nov 17.

The following slate was offered: Dr Thomas McGoldrick as president, replacing Dr Henry Joachim, Dr John D'Albora, president-elect, Dr Augustus Harris, vice president, Dr Joseph Raphael, secretary, Dr Thomas Wood, associate secretary, Dr Matrice Dattelbaum, treasurer, Dr Arthur Holzman, associate treasurer, Dr Jacques Rushmore, librarian, and Dr Edwin Maynard, associate librarian.

The nominations were preceded by lectures on dysentery. Those who spoke were Dr Albert A. Berg, surgeon-in-chief at Montefiore Hospital, and Dr Joseph Felsen, director of pathology at the Bronx Hospital.

A REGULAR MEETING of the Woman's Auxiliary of the Kings County Medical Society was held on Nov 10. Mrs Edwin A. Griffin, president, presided. Dr Irvin Sands spoke on Mental Hygiene. Mrs Samuel Zwerling, historian, read a report on the year's work. Mrs Paul Eschwald, chairman of the medical economics committee, also gave a report. Mrs Frederick Elliott, chairman of program, outlined the programs for the coming year. Refreshments were served. About one hundred were present.

Nassau County

A PLAN TO RELIEVE congestion in the hospitals of the county and improve the hospitalization of the needy, by increasing the medical funds of town welfare officers and permitting, wherever possible, a choice of hospitals, is under consideration by the Nassau County Medical Society and county officials.

After Dr Louis H Bauer of Rockville Centre and Hempstead, outlined this plan at a meeting of the society and officials in the supervisors' chambers, it was voted to appoint a committee to investigate.

The committee, it was suggested, should discuss the problem with the commission on government revision, of which Earl J Bennett is chairman, so that any definite plan adopted will conform with the new charter and will promote cooperation between doctors and the county health and charity departments.

Medical News

REGULAR EXAMINATIONS BY the family physician were advocated as the most effective means of detecting and controlling heart afflictions at a meeting of the Broome County Medical Society on Nov 10 at Lourdes Memorial hospital by Dr R. E Morgan, professor emeritus of clinical medicine at Temple University, Philadelphia

"Cardiac afflictions are among the most frequent causes of death," Dr Morgan pointed out "Diagnosis and treatment of such conditions are well within the ability of the average doctor at first-hand, without recourse to elaborate instrument studies" There is hope for recovery for many suffering attacks of acute cardiac condition

DR. JESSE G N BULLOWA, clinical professor of medicine, New York University Medical College and visiting physician at the Harlem Hospital, spoke on "The Management of Pneumonia" before the Binghamton Academy of Medicine on Nov 10 at the Monday Afternoon club

Chemung County

THE ONE HUNDREDTH ANNIVERSARY of the Chemung County Medical Society was observed at a dinner meeting in the Mark Twain Hotel, Elmira, on Nov 21

From a handful of "country doctors" in the little city on the banks of the Chemung shortly after the new county had been whittled from old Tioga County, the society has grown to include nearly one hundred physicians

To the celebration came officers of medical groups in Steuben, Schuyler, Broome, Tioga, Tompkins, and Cortland Counties and Dr Floyd F Winslow of Rochester, president of the State Medical Association.

Dr Arthur W Booth reviewed the history of the Society during its one hundred years

Dr Ross G Loop told of methods and treatments used by the profession during the last one hundred years Dr Anna M Stuart told of women physicians in Chemung County medical history

Dr Reeve B Howland had gathered exhibits connected with medical practice, instruments, and pictures of former physicians

"Focal Infection and Its Relation to Systemic Diseases"—By Arthur J Horton, M D, Assoc. Phys, Mary Immaculate Hospital, Asst Phys Queens General Hospital

"Medico-Dental Cooperation in Everyday Practice as Related to Hospital Practice."—By M. I Schamberg, M D, D D S, Att. Oral Surgeon, Bronx Hospital, Cons Plastic Surgeon, Hospital of Joint Diseases

The Annual Meeting of the Medical Society of the County of Queens was held on Nov 24 The program

Election of officers and annual reports, remarks by Mrs Irving Ponemon, President Woman's Auxiliary to the Medical Society of the County of Queens, Inc., "Organized Medicine—A Service to the Community"—By Charles Gordon Heyd, M D, Pres dent of the American Medical Association, address by the President, James M Dobbins M D, Pathologic Exhibit and Demonstration, Collation.

Dr Heyd was elected the first honorary member of the Queens County Society, and was given a life membership certificate

The election resulted as follows

Dr Henry C Eichacker, president-elect, Dr Frank R Mazzola, secretary, Dr Chester L Davidson, assistant secretary, Dr William T Berry, treasurer, Dr Daniel J Swan, assistant treasurer, Dr Herbert L Langer, Dr Vincent Juster, and Dr Edward A. Veprovsky, censors, Dr Joseph Wrana, delegate to the State Society Dr William Berry, Dr Albert L Voltz, and Dr Henry C Courten, trustees

At the same time, the annual meeting of the woman's auxiliary to the Medical Society, was held. The election resulted in the selection of the following

Mrs Elmer Kleefeld, president-elect, Mrs Henry C Eichacker, vice-president, Mrs Harold Foster, secretary, Mrs Alfred S Ambler, treasurer, Mrs John J Kilcourse, assistant treasurer, Mrs Thomas d'Angelo, historian, Mrs Irving Ponemon, Mrs John Scannell, Mrs Isidore Epstein, Mrs George Jantzen, and Mrs Walter Lynch, delegates to the state auxiliary, district representatives, Mrs Edward M Douglas, Mrs John G Hill, Mrs James De Rose Mrs Elmer Amerman, Mrs Frederick Gartner, Mrs A W Victor, M A Sanders Mrs Anthony Giambalvo, and Mrs Gerald Pauley

On Jan. 1 Dr James R Reuling, of Bay-side, will become president of the Medical Society as he was president-elect last year Mrs John W Mahoney, Flushing, will become the president of the auxiliary

A CLINICAL CONFERENCE on cancer re-

search was held at the Memorial Hospital of Queens, at Jamaica, on Nov 24, with Dr G T Pack as the speaker Discussion was led by Dr Arons and Dr Barland.

Rensselaer County

NOMINATION OF OFFICERS for the ensuing year took place at the November meeting of the Medical Society of Rensselaer County at the Troy Health Center

Officers named in the report of the nominating committee, include

President, Dr Stephen H. Curtis, vice-president, Dr Hugh V Foley, secretary, Dr Leo S Weinstein, treasurer, Dr John F Russell, censors, Dr G E Martin and Dr George D Hoffeld, delegates, Dr W B D VanAuken and Dr A J Hambrook, and alternates, Dr Clement J Handron and Dr H C Gordinier

Election of officers took place at the Health Center December 8 The annual meeting and banquet of the society was conducted Wednesday evening, December 9 in the ballroom of the Hendrick Hudson

Dr George W Crille, head of the Cleveland Clinic, Cleveland, O, was one of the guest speakers Another was Fred E Elliott, chairman of the Medical Economics committee of the State Medical Society

Rockland County

THE WOMAN'S AUXILIARY to the Rockland County Medical Society was organized at a meeting at Summit Park Recreation Hall on November 4, and the wives of the doctors were addressed by Mrs Edward A. Flemming of Brooklyn organization chairman of the State of New York.

The Executive Committee of the Women's Auxiliary of the Rockland County Medical Society met at the home of Mrs S W S Toms, South Nyack, on November 9 The business meeting was conducted by Mrs Toms and another meeting of all the wives of the doctors in the county was scheduled for November 16 at Summit Park Recreation Hall, Pomona.

The officers are president, Mrs S W S Toms, president-elect, Mrs A. N Selman, first vice-president, Mrs W J Ryan, second vice-president, Mrs F A Glass, recording secretary, Mrs E H Kline, corresponding secretary, Mrs J Pomerantz, treasurer, Mrs L. G Weishaar, historian, Mrs George M. Richards

TWO HUNDRED AND FIFTY neighbors and friends of Dr Charles D Kline of Nyack honored him Nov 12 by a testimonial dinner at the Hotel St. George marking his seventieth birthday

Appointment of the committee was suggested by Supervisor J Russell Sprague, after Supervisor A. Holly Patterson of Hempstead pointed out his town budget has already been approved and tax warrants issued, making it impossible to provide additional funds. Other board members agreed this condition prevailed in all towns and cities.

Congestion in the hospitals, it was said, has been aggravated by the hospitalization of many cases not formerly so handled and by the necessity of hospitalizing relief workers and other needy persons, for whom the town welfare authorities have no funds to provide medical treatment which could be given at home.

THE WOMEN'S AUXILIARY to the Nassau Medical Society heard Dr William H Ross, former president of the New York State Medical Society, at its meeting Nov 10 at the Nassau Hospital auditorium. Mrs A M Bell of Sea Cliff is president.

THE MEDICAL SOCIETY of the County of Nassau elected the following officers at its meeting on Nov 24: President-elect Louis H Bauer, Vice-President Myron R. Jackson, Secretary-Treasurer Herman G Wahlig, Censors E K. Horton, R E Lease, W F Lewis, N H Robin, E N Whitcomb, Delegate to the State Society (two years) L H Bauer, Delegate to the Second District Branch G B Granger, Members of Workmen's Compensation Committee S A Combes, W F Lewis, Jr, L A Van Kleeck. Dr Henry B Smith president-elect, will become president.

Niagara County

DR JAMES K QUIGLEY, professor of obstetrics at the University of Rochester, addressed the Niagara County Medical Society on Nov 10 at Lockport, on "Caesarian Section, with Particular Reference to the Indications for its Performance."

Dr Francis C Goldsborough, professor of obstetrics at the University of Buffalo, led the discussion.

A subscription dinner was given for Drs Quigley and Goldsborough preceding the meeting.

Onondaga County

DR MORTIMER G BROWN was nominated for president of the Syracuse Academy of Medicine at a meeting in the University club Nov 17.

Other officers nominated are Vice-president, Dr David F Gillette, secretary, Dr Leon E Sutton, treasurer, Dr Foster C Ruhson, board of censors,

Dr Donald S Childs, Dr Carl E. Muench, Dr Brooks W McCuen, Dr E. S. Shepard and Dr P K Menzie, board of trustees, Dr Robert K. Brewer, Dr Herbert C Yeckel and Dr Floyd R. Parker.

Papers were read at the meeting by Dr Edward C Reifenshtein and Dr Tracy L Bryant.

THE WOMEN'S AUXILIARY to the Onondaga County Medical Society met on Nov 10 in the Nurses' Recreation Hall, University Hospital of the Good Shepherd. Dr Ferdinand Schoeneck spoke on "Maternal Welfare." A musical program and social hour followed.

A TESTIMONIAL DINNER to Dr Thomas H Halsted was given by the Syracuse Eye, Ear, Nose and Throat club of physicians on Nov 10.

Dr Halsted is retiring from active practice after forty-five years as a specialist of eye, ear, nose, and throat ailments. He was a pioneer in this field in Syracuse.

He was presented with a brief case by the club and in his response told of his reminiscences of professional life and training. Dr Halsted retires to become a representative of a New York City financial house.

Ontario County

"POST-GRADUATE STUDY" was the topic of a paper given by Dr A. W. Armstrong at a monthly meeting of the Canandaigua Medical Society on Nov 12. Dr J F McAmmond, of North Main Street, was host, dinner being served to 17.

Guests were Dr Hans Hansen and Dr Parker G Borden, of the Veterans' Hospital, and Dr J A. Crowther, of Honeoye. The meeting on Dec 10 was with Dr F C McClellan, North Main Street. Dr Robert M Ross, of Brigham Hall, read a paper on "Mental Aspects of the Average Patient."

Queens County

A JOINT MEETING of Medical Society of the County of Queens, Inc and Dental Profession of the County of Queens was held on November 30. The program

"The Relationship of Dentistry to Intra-oral Cancer"—By William J Hoffman, MD, Dir Tumor Clinic, Queens General Hospital, Adj Radiol, Lenox Hill Hospital.

"Medico-Dental Cooperation in Everyday Practice as Related to Office Practice."—By Louis I Abelson, DDS, Past President of the Allied Dental Council and of the Eastern Dental Society, Past Chairman of the Prosthodontia Section of the First District Dental Society.

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

Physician and Patient—Fee of Consultant

A case recently decided by the Supreme Court of this State brought under consideration the question that arose when a consultant was called into a case by the physician in attendance and the claim was later made that the consultant was entitled to no fee on the grounds that he never was properly employed*.

The case arose out of the treatment of a small boy for mastoiditis. He had been under the care of a certain Dr. Y upon whose advice the father of the child engaged a Dr. H. T. to take over the care of the case. Dr. H. T. continued in charge for a period of weeks, and determined that an operation was necessary. That fact he communicated to both Dr. Y and the father. He also told Dr. Y that he felt unable to perform the operation himself, and suggested that his brother, Dr. G. T., with whom he engaged in a joint practice as partners, be called in. Thereupon at the request of Dr. Y, Dr. G. T. performed a single mastoid operation upon the patient. The usual hospital consent to the operation was signed by the parents before it was actually performed.

Thereafter, the two doctors, T., as partners rendered a bill to the child's father, and it being unpaid, suit was instituted to enforce its collection. The defendant claimed that he had never engaged Dr. G. T., the surgeon, to render any services to his son, and that he never even consented to an operation at his hands. He claimed he had engaged Dr. H. T. solely for that purpose.

The attorney for the plaintiffs made an application to the Court for summary judgment. Upon the hearing of the motion there was produced a letter signed by the defendant, dated some six months after the operation, addressed to "Dr. T." in which he stated he felt "terribly about not having taken care of your bill before," and that when business conditions improved he would "straighten up our affairs with you." Later defendant had written Dr. T. that on his return from a trip he had found certain letters from a collection agency concerning the account, and had ended his letter saying

"You can rest assured that you will be paid in full if you will be patient with me. I am enclosing a small check for \$50 which may help a little and I will try and gradually reduce the bill by sending you a small payment from time to time."

Upon the facts as outlined above presented in the form of pleadings and affidavits, the Court granted judgment in favor of the plaintiff doctors, and said in the course of his opinion

It is inconceivable that the defendant did not know what doctor was to perform the operation upon his son. It is inconceivable that he had no knowledge as to who was treating and caring for his son during the period of convalescence after such operation. Ordinary paternal interest would have compelled a father to ascertain these facts in the circumstances. The plaintiff, Dr. H. T. had attended the infant son. The plaintiff, Dr. G. T., had successfully performed a serious operation. The plaintiffs are partners in the practice of their profession. Had the services been performed without the consent or knowledge of the defendant, he would still be liable.

The Court in so ruling cited as authority an interesting case decided in the Courts of Pennsylvania nearly fifty years ago which is one of the few reported cases in which the Courts have written opinions on the subject of the right of a consultant to be paid in the absence of a specific understanding.

In that case* a claim was made by a physician against the estate of a decedent to recover a fee for services claimed to have been rendered during the last illness of S., the decedent. S. had been afflicted with a brain disorder and in the beginning of his illness consulted Dr. H. on various occasions, who examined and treated him and thereby became familiar with his case. When S. finally became acutely ill he was at a considerable distance from Dr. H. and was living alone, being attended by certain servants. His only relative, a sister was at the time travelling in Europe. A business associate of S. called in a Dr. F. to attend the sick man, who soon became paralyzed and his thought and speech became

*Tobey v. Nelson, 150 Misc. 346

*Matter of Sherman's Estate, 6 Penn. Co. Ct. Rep. 225

Distinguished associates of Dr Kline delivered eulogies. A plaque in appreciation of Dr Kline's services to the Nyack Hospital and the rest of the community will be mounted in the hospital. This tablet was purchased by subscription through the volunteer committee which arranged the testimonial dinner.

With Judge Patterson presiding, the speakers comprised Dr Gerrit F Blauvelt, dean of Rockland County physicians and honorary toastmaster, Dr S R Monteith, who spoke for the younger doctors, Robert Walmsley, chairman of Nyack Chapter, American Red Cross, Dr Samuel Brown, heart specialist, Dr George A Leitner and Judge Arthur S Tompkins.

St Lawrence County

THE ANNUAL MEETING of the St. Lawrence County Medical Society was held Nov 19 at the Seymour House at Ogdensburg.

The meeting was held in the afternoon, following a dinner at 12 30. The women received a special invitation to the meeting, to discuss plans for forming a women's auxiliary to the society.

The program included the president's address, "Reminiscences of the Medical Profession for the Past Fifty Years," by Dr Frank F Williams, Canton, the vice-president's address, "The Board of Supervisors and the Medical Profession," by Dr William H Mulholland Heuvelton, and a lecture, "Mid-Childhood Hip-Joint Disease," by Edward K. Cravener, Schenectady.

At the election of officers Dr S Pope Brown of Potsdam was elected vice-president to succeed Dr Mulholland who was named president to succeed Dr Williams. Dr Samuel W Close was re-elected secretary for the forty-ninth consecutive term.

Other officers named were Treasurer, Dr L T McNulty, censors, Drs P G Taddiken, F C Mason, and M J Stearns, delegate to the house of delegates for 1937-38, Dr W G Cooper, alternate, Dr F C Mason, delegate to the district branch, Dr R L Stacy, alternate, Dr S W Close.

Steuben County

DR. C M LAPP of Corning was elected president of the Steuben County Medical Society at its annual meeting on Nov 12 at the Salubria Inn near Bath.

Other officers elected were vice-president, Dr A E. Richmond, secretary and treasurer, Dr R J Shafer, censors, Dr Ernest Smith, Dr L A Thomas, Dr Stuart Bean, Dr M A. Place, delegate to the State

Medical Society for two years, Dr H. B. Smith.

The principal talk was given by Dr Lincoln of the Mt Morris Tuberculosis Sanatorium, who described improvement in control of tuberculosis.

The question of recommending hospitalization insurance came up at the meeting and the consensus was that most of the doctors of Steuben County favor the idea but feel that the movement should spring from the staffs of the hospitals which would be involved rather than from the Medical Society.

Tompkins County

"MEDICAL SOCIETIES MUST be constantly alert to the threat of a socialized profession," Dr Terry Townsend warned the Tompkins County Medical Society on Nov 19. "There is a growing structure of lay organizations designed to end individualistic medicine."

"Their tendency now is toward the institution of public health insurance. Community units must be prepared to counteract this tendency with a scheme of their own for the care of the sick in the lower income brackets."

Presence of Doctor Townsend, chairman of the state society's committee on trends, attracted a heavy attendance from Chemung, Tioga, Cortland, Seneca, and Schuyler Counties to the meeting, presided over by President Henry B Sutton. It was held in the Nurses Home at Memorial Hospital, Ithaca.

As an added speaker, President Sutton introduced Dwight S Anderson of New York City, director of the state society's bureau of public relations. He described the bureau's method for acquainting laymen with medical methods and progress through the dissemination of literature to hundreds of recognized periodicals.

Dr Joseph Lewis led a round table discussion of both speeches, presenting concrete methods by which it is possible to ward off the threat of state medicine and increase the flow of favorable publicity. The fifty-five members present closed their monthly meeting with a dinner.

Wayne County

DR. LUCIUS H SMITH, whom "nearly everyone in Palmyra regarded as a god-father," according to newspaper accounts, died at his daughter's home in Albany on Nov 18 of diabetes. He had retired last summer after half a century of practice. He was a leading figure in his county society.

Across the Desk

England Swimming in a Sea of Medicine

A LITTLE NEWSPAPER ITEM of only a dozen lines was handed to this scribe a few days ago by one of the leading men of the State Society on the trip to the meeting of medical editors and secretaries in Chicago. It was little, but told volumes. It reported, on the authority of Sir Kingsley Wood, British Minister of Health, that in twelve years the prescriptions issued in England and Wales have increased from 38,200,000 to 62,400,000, an increase mostly due, he said, to the growth of the "bottle habit."

From other sources we learn what the "bottle habit" is. Everybody who visits a doctor insists on having a bottle of medicine, which in England is supplied by the physician and so costs the patient nothing under their "panel system" of state medicine. On the shelf is a long row of bottles of staple compounds, and when the patient comes in he gets a brief once-over, or a sharp query, "What's the matter now, Jim?" down comes a bottle, with a rapid fire of instructions, and out goes Jim. An American physician visiting England not long ago questioned a couple of railroad workers about the panel system and found them enthusiastic about the marvelous efficiency of their doctor. He could put thirty patients through his office in sixty minutes. Could any American doctor beat that? And probably every one of them came out tightly grasping a bottle of medicine.

Medicine for the Mind

No doubt many of the patients had little or nothing the matter with them, and received harmless mixtures that satisfied their "bottle habit" and were chiefly of mental help. Every doctor has patients of that sort. An amusing incident of this kind is related by a veteran practitioner of Indianapolis, Dr. William N. Wishard, who tells some of his reminiscences in his state medical journal. He says

I recall many cases where a little understanding of the psychology of my patients has helped greatly. I happen to think of one just

now which is rather amusing. A little lad about seven years old complained to his mother that he was "car-sick" when he got on the train. They were starting to the Coast of Maine the next morning, and she appealed to me and said, "Is there something that can be done for him?" I asked to see the boy, and looked at his tongue, and then looked as wise as I was capable of looking and went over his chest, felt his pulse, and I said, "Yes." I took a long shot doing this. I knew there was a wrong psychological element in this case. He was traveling a good deal and had acquired the habit of getting sick when on the car. After making the necessary and apparently serious examination of the lad I went to the drugstore and got a couple of one-half grain tablets of methylen blue, and said to the boy's mother, "Give him one tablet tonight when he goes to bed." I impressed upon the young man's mind the fact that after he got up in the morning if the urine was blue and he would take the other tablet one-half hour before the train started he would not be car-sick at all. I learned that he ran to his mother in the morning and said, "Oh, Mother, it's blue, it's blue!" and then he watched the clock and anxiously awaited eight o'clock when he took the other tablet, and his mother wrote that when they reached their destination he had not been car-sick at all.

I recite that incident because it is suggestive of carefulness in judging as to what extent a patient's illness is influenced by his mental attitude. Sometimes, however, you may get tripped. You have to use a good deal of common sense and a good deal of careful thinking as to what kind of patient you are dealing with. You have got to know more than medicine in dealing with some patients.

What to Do When the Family Acts Up?

One time when you have "got to know more than medicine," too, is when you are dealing with the patient's family. This part of medical practice has been neglected by the schools, and suggests a new course that might be offered. How to treat the patient? Plenty of instruction there. How to handle the patient's family? Nothing at all! Yet just at a critical moment the relatives may come barging into the picture and start to upset everything. What is

so impaired that it was impossible for him to intelligently convey to Dr F his past symptoms. Dr F therefore proceeded by letter to obtain information and professional advice from Dr H with respect to the medical history of the patient and the form of treatment to be followed. The patient, however, died from the illness.

After death Dr H made a claim for compensation which the Court allowed on the theory that a principal will be bound "by the acts of a self-constituted agent where his own neglect or the act of God has rendered those acts necessary for his self-preservation or for the well-being of society." The Court in so ruling made the following pertinent observations:

The spirit in which this rule is to be expounded should be in unison with the character of the relations which the parties have themselves established with each other, and should be liberal just in proportion as those relations become more intimate and involve delicate questions of duty and responsibility. To say that the discretion to act promptly in an emergency, which a patient necessarily gives to his physician, is larger than that which a merchant gives to his drayman, is simply to say that a man will resign more of his own authority to the will of the person who is to save his life, than to that of the person who is to take care of his trunks. The trust, which includes the power for its exercise with which the patient vests his physician, is often practically unlimited, because it may require to be executed at a time when disease has taken away all ability to restrict it. The patient is not to be left to die, on the plea that during such an interval, no act of his adviser can be valid, for want of his direct approval. Or, the doctor may suspect the presence of an obscure disease, which if it exists, demands heroic treatment. To communicate the suspicion to the sick man will probably finish him on the spot, may he not solve the doubt by consulting a specialist?

Mass on Tongue

A physician who specialized in the treatment of cancer was consulted by a young man with reference to complaints of a mass which had developed on his tongue. Examination showed that he had on the midline of the dorsum of his tongue a hard, raised but not definitely ulcerated mass approximately seven by fifteen mm surrounded by a reddened area. The doctor took a biopsy and the pathological report was as follows: "Thickened epithelium with slight down growth. No definite evidence of carcinoma." The doctor also took blood from the patient for a Wassermann test and received a negative report. When the patient returned a

week later the doctor explained the reports to him and suggested Radon treatment as he feared that in spite of the reports the patient might be developing a cancer. The same day he implanted two Radon seeds in the mass and sent the patient home with the seeds so imbedded. The patient was instructed to return to the doctor in a week. He never returned for treatment and was never seen by the doctor subsequent to that time.

The next time the doctor heard from the patient was when a malpractice action was instituted against him in which the charge was made that the doctor had been negligent in his administration of Radon. It was claimed that the implantation of the Radon seeds caused the tongue to be severely eroded so as to destroy a portion of the tissues about the size of a quarter.

The action was never brought on for trial by the plaintiff's attorney and an application was duly made to the Court on behalf of the defendant doctor for an order dismissing the action for failure to prosecute. Before the said motion could be argued, the plaintiff consented to discontinue the action against the doctor.

Treatment of Neuritis

A physician engaged principally as a specialist in roentgenology was consulted by a woman with complaints of pains and aches in the right side of her neck, shoulder, and right arm which she stated had been of several months duration. The doctor, after examination, made a diagnosis of neuritis. He found evidence of pain and tenderness on pressure over the shoulder and upon motion of the arm and shoulder. He advised treatment by the application of a high frequency current and administered five such treatments to the patient. Each of said treatments was of ten minutes duration and administered by a high frequency tube of the neck and applicator type.

Although the patient was to receive further treatments, after the fifth treatment she failed to appear at the doctor's office, and hearing nothing from her for sometime he instituted action against her to recover his fee for professional services rendered. The patient undertook to resist the doctor's action by interposing a counterclaim charging him with malpractice in the treatment which he had given her. However, when the case came on for trial, a conference before the trial judge resulted in a withdrawal of the counterclaim and in a judgment in favor of the doctor in the full amount of his bill.

aware of the altered emphasis of illness. Have we not insisted too strongly that only such pathology as can be heard or felt, or tested and measured in the laboratory, is true pathology? Have we not specialized our observations so intently that we do not see the organism because of the organs? Have we not institutionalized medical practice to such a degree that we think more of the disease than we do of the man as an individual and as a member of a social group? An affirmative answer, I believe, should be given to each of these questions?

He cited further the vogue of mental healers as proof that people are growing more

emotional and more overstrained nervously. At the same time we live in an age of high-speed and delicate machinery, where nerves awry can play havoc, and even plunge nations into catastrophic conflicts and crash civilization into chaos, as Lord Horder hints. No greater crisis has ever faced a distraught world. Never has the skill of wise physicians been more imperatively needed. If the profession can help keep America sane in a wild world that makes Bedlam seem like a rest cure, it will, as the Romans used to say "deserve well of the Republic."

MEDICOLEGAL ASPECT OF ARTIFICIAL INSEMINATION

The question of the legitimacy of a child born in wedlock, as a result of artificial insemination from a donor other than the father, has not been brought to trial as yet. It is with this in mind that Frances I Seymour and Alfred Koerner, New York (*Journal A M A*, Nov 7, 1936), present their discussion in the hope of answering some of the many questions asked by physicians.

First, the question of the legality of the mother's position is discussed. Adultery, by the New York State law, is defined as "the physical relationship between a woman or man with a partner other than the legal mate." This interpretation automatically dispenses with any such question in a case of artificial insemination. However, it has been found necessary and advisable to insist that the woman's husband be made to give a written consent that his wife be inseminated. The authors use a specific form. The signatures of both the husband and wife are affixed to the document and sworn to before a notary. The consent sheet is signed in duplicate, notarized and witnessed. These consent blanks are then separated and placed respectively in the vaults of separate banks and forgotten unless a legal complication should arise.

These consents legitimize the child under the present New York laws and establish it as the legal heir of the family unit. It also acts as mental binder on the husband in that he knows he can never deny having authorized the creation of his wife's child. There is little likelihood of the

mother's ever bringing suit except in the event of cross-insemination when the surgeon allowed the identity of the donor to become known.

Possibilities of blackmail by the donor can be eliminated by having him deliver his specimen at a different address or apartment or at a different time than the arrival of the patient. Another simple method is to keep the two hospitalized during the period. It eliminates the question of possibility of blackmail by the donor. He has no possible way of knowing who the recipients are and no one can learn the identity of the donor.

It is preferable that the donor be married, as it eliminates a tendency to promiscuity. However, notarized permission from the legal wife stating that her husband may participate in this scientific venture is essential. Such a venture on the part of a husband may be a violation of the laws against adultery. Therefore, as in New York State, if the wife is cognizant of the condition and has so signified in writing, she is unable to obtain a divorce on these grounds, as condoned adultery nullifies grounds for divorce.

Another phase to the question arises when the sterile husband asks to have a relative be the donor. This should never be consented to. In selecting a donor, it would be well to choose one whose blood group corresponds with that of the husband. A child born in wedlock is the legal heir unless his paternity is disproved and a "final adjudication is handed down by a court."

indicated then? A war-club or a battle-axe? Many a harried medical man would like to have one handy

It is chiefly when a diagnosis of psychosis is made that the family begin to act up, says a New Orleans physician, Dr L. L. Cazenavette, in a paper read before his state medical society. The first mistaken idea that crosses the family brain is that mental disorder is always hereditary. Therefore such a diagnosis is, first, a reflection on their ancestors, and secondly, and worse yet, a suggestion that the whole family may be slightly cracked. Perhaps it is no wonder that a fight is put up by the sisters and the cousins and the aunts, not to mention the mothers and brothers and the others

Well, let us suppose that the doctor has finally convinced the embattled family that his diagnosis is correct, then the questions arise, what to do for the patient and what to do with the patient. Just let the doctor suggest a mental hospital, and the battle is on again, more violent and furious than before. If the patient is in a depressed state, a "tonic" to elevate him to a higher plane is suggested, if he is excited and restless, a "quieting" drug is declared the thing. The doctor is asked to give a drug to put the patient to sleep, with the naive assurance that all the patient needs is rest, and "after a good rest he will be all right again"

Delusions About Dementia

The panic of the family, while unreasonable, is at the same time explicable. Visions of straitjackets and padded cells rise before their imaginations, the medieval conviction that the demented were possessed by demons floats in the back areas of their consciousness, the horrid thought of an ineradicable stigma on the family burns like a branding iron, erroneous ideas of the "madhouse" as a screaming Bedlam inflame the family fears. As a matter of fact, cases sometimes occur called "reactive psychosis," where mothers or sisters lose their own mental balance in their upset over the dementia of those they love. It is recommended, to avoid exciting the relatives, that even the word "dementia" be avoided in favor of milder terms or words like "schizophrenia," which they never heard before.

They should also be assured that mental illness often has nothing to do with heredity

Dr Cazenavette recalls that Rosenau presents as physical causes of mental disorders the infectious diseases, syphilis, typhoid, influenza, scarlet fever, septicemia, acute and chronic poisoning from drugs, alcohol, endogenous poisoning from nephritis, heart disease, and diabetes, disease of the thyroid and head injuries. Other forms of insanity result from inherent abnormal mental make up of the patient, others from vascular changes incident to advanced age. It should not be considered a disgrace to have a member of one's family so afflicted. Such conditions may arise in otherwise perfect ancestry

And what is more, the records of our mental hospitals show a high rate of patients discharged as cured, and the family may be encouraged to expect the patient home soon, restored to normal, and all local gossips and critics silenced and confounded

The European Madhouse

If all madmen are sent to the madhouse, who would be left, in Europe at least, to act as keepers? Lord Horder, our honored guest last spring, said the other day in an address in Edinburgh that "we should preserve our mental poise while large sections of humanity are losing it." Mental poise may save civilization, he added, "but if we develop national hysteria or national hypochondriasis, this unique opportunity will be lost forever." As we survey the European scene, it must be said that national hysteria seems spreading so rapidly as to be getting almost beyond control

Is it due to the overstrain of modern life and its nervous excitations? Dr Walter B. Cannon, of the Harvard Medical School, based his convocation oration before the American College of Physicians in Detroit last spring on the fact that "in modern life infections have diminished and nervous strains have increased." He added

The nervous system is all-pervasive. It can have effects in remote and secluded portions of the body, far from any obvious lesion. Because it is universal in its effects, disorders which involve the nervous system require consideration of the organism as a whole. But well-nigh all diseases involve the nervous system, because they arouse fears and anxieties and worries, and these feelings are expressed in demonstrable bodily effects.

I have questioned whether we as members of the medical profession have been sufficiently

author believes that only one per cent of the total cases has surgery indicated because of failure of good medical treatment after a period of five to six months

The medical treatment advocates early diagnosis, individualization, complete co-operation of the patient, removal of foci of infection, high caloric diet, improved general hygiene, psychotherapy and under medication, quinine, iodine, eserine (physostigmine), adrenal cortical substance, barbiturates, ovarian substances, and insulin

This text is an abrupt disagreement with the usual teaching that surgery is the solution in Graves' disease. Because of this, there is much to command the attention of the internist

PAUL C ESCHWEILER

Diseases of the Nose, Throat and Ear for Practitioners and Students Edited by A Logan Turner, M D Fourth edition, revised and enlarged Octavo of 473 pages, illustrated Baltimore, William Wood and Company, 1936 Cloth, \$6.00

This is a revised and enlarged edition of the already very acceptable book created by an Edinburgh group and edited by A Logan Turner It is designed for students and practitioners, and is readily understandable

Many of the illustrations are schematic rather than anatomic but are correct in detail and proportion, and perhaps illustrate better the points to be made For this reason, and because anatomic as well as most other descriptions, are stated simply in plain language, the volume is a practical one of modest size for reference and for students Lengthy detail is not entered into, much to the credit of the authors, but treatment of each subject is adequate and almost everything of importance is covered at least in a brief way

There are no specially noteworthy features—it is just a good dependable book on the Ear, Nose and Throat and considerable peroral endoscopy

CHARLES R. WEETH

The Eye and Its Diseases By 82 International Authorities Edited by Conrad Berens, M D Octavo of 1254 pages, illustrated Philadelphia, W B Saunders Company, 1936 Cloth, \$12.00

Those who have known of the preparation of this book, have awaited it with a great deal of anticipation and interest. The subject material has been contributed by internationally known ophthalmologists who are recognized as authorities in the various fields covered by their contributions. The general make-up of the volume is splendid

Most of the illustrations are excellent and serve their purpose adequately. Time and use only will reveal, for a possible future edition, what should be more fully elaborated, or what might to advantage be presented in a more condensed form

The index is very complete, and each chapter is followed by a more or less extensive bibliography

To this reviewer, it seems as if we have in this volume the most up-to-date and inclusive reference text on diseases of the eye, and he ventures the prediction that it will be recognized, for some time to come, as the standard

To the editor is due a great deal of praise for an outstanding work

CHARLES A HARGITT

Pathological Physiology and Clinical Description of the Anemias By William B Castle, M D and George R Minot, M D Edited by Henry A Christian, M D Octavo of 205 pages New York, Oxford University Press, 1936 Cloth, \$3.00

A glance at the authors' names, of course insures this to be an authoritative discussion of the subject.

In the introduction, it is stated that anemia, to produce symptoms in a moderately active individual, requires that the values for the concentration of the red cells or hemoglobin be reduced about one-half. When the blood loss is rapid, as from hemorrhage, a considerably smaller loss may produce serious signs. A gradual reduction may proceed to quite an extreme degree without symptoms, especially when the patient is resting in bed.

Pallor does not always denote anemia, as all have noted, but may be due, the authors state, to constriction of the peripheral vessels as in fainting, or increase of fluid in the tissues, as in myxedema or nephritis. Patients with lesser grades or even more marked anemia may not appear pale, because of dilatation of the peripheral vessels, the pink cheeked anemia, ("anemia rubra," Osler)

A comprehensive classification of the anemias is presented. Among the rarer types, the macrocytic anemia which may occur in pellagra is discussed, as is sometimes seen in individuals subject to chronic alcoholism or gastro-intestinal disorders, probably due to deficiency of vitamin B

With regard to treatment, attention is called to the necessity of establishing a diagnosis before, and not after, the blood picture has been obscured by indiscriminate therapy. Transfusion is believed to be only rarely indicated in pernicious anemia because improvement will usually begin

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers

REVIEWS

The Normal Diet and Healthful Living By W D Sansum, M D, R. A. Hare, M D, and Ruth Bowden, B S Octavo of 243 pages New York. The Macmillan Company, 1936 Cloth, \$2 00

The author has accurately recorded for the layman a simple description of metabolic processes and the physiology of digestion. This is followed by chapters on allergy, obesity, undernutrition and hygiene. The book contains a good compilation of menu plans

WILLIAM S COLLENS

Exophthalmic Goiter and Its Medical Treatment By Israel Bram, M D Second edition Octavo of 456 pages, illustrated St. Louis, C V Mosby Company, 1936 Cloth, \$6 00

This book presents the author's views on the medical treatment of Graves' disease. His text is based on the theme that "al-operate with the properly equipped internist get well" Conversely, that thyroidectomy is only indicated in a little over two per cent of all cases of Graves' disease. The

author believes that only one per cent of the total cases has surgery indicated because of failure of good medical treatment after a period of five to six months

The medical treatment advocates early diagnosis, individualization, complete co-operation of the patient, removal of foci of infection, high caloric diet, improved general hygiene, psychotherapy and under medication, quinine, iodine, eserine (physostigmine), adrenal cortical substance, barbiturates, ovarian substances, and insulin

This text is an abrupt disagreement with the usual teaching that surgery is the solution in Graves' disease. Because of this, there is much to command the attention of the internist

PAUL C. ESCHWEILER

Diseases of the Nose, Throat and Ear for Practitioners and Students Edited by A. Logan Turner, M.D. Fourth edition, revised and enlarged. Octavo of 473 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth, \$6.00

This is a revised and enlarged edition of the already very acceptable book created by an Edinburgh group and edited by A. Logan Turner. It is designed for students and practitioners, and is readily understandable.

Many of the illustrations are schematic rather than anatomic but are correct in detail and proportion, and perhaps illustrate better the points to be made. For this reason, and because anatomic as well as most other descriptions, are stated simply in plain language, the volume is a practical one of modest size for reference and for students. Lengthy detail is not entered into, much to the credit of the authors, but treatment of each subject is adequate and almost everything of importance is covered at least in a brief way.

There are no specially noteworthy features—it is just a good dependable book on the Ear, Nose and Throat and considerable peroral endoscopy.

CHARLES R. WEETH

The Eye and Its Diseases By 82 International Authorities. Edited by Conrad Berens, M.D. Octavo of 1254 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$12.00

Those who have known of the preparation of this book, have awaited it with a great deal of anticipation and interest. The subject material has been contributed by internationally known ophthalmologists who are recognized as authorities in the various fields covered by their contributions. The general make-up of the volume is splendid.

Most of the illustrations are excellent and serve their purpose adequately. Time and use only will reveal, for a possible future edition, what should be more fully elaborated, or what might to advantage be presented in a more condensed form.

The index is very complete, and each chapter is followed by a more or less extensive bibliography.

To this reviewer, it seems as if we have in this volume the most up-to-date and inclusive reference text on diseases of the eye, and he ventures the prediction that it will be recognized, for some time to come, as the standard.

To the editor is due a great deal of praise for an outstanding work.

CHARLES A. HARGITT

Pathological Physiology and Clinical Description of the Anemias By William B. Castle, M.D. and George R. Minot, M.D. Edited by Henry A. Christian, M.D. Octavo of 205 pages. New York, Oxford University Press, 1936. Cloth, \$3.00

A glance at the authors' names, of course insures this to be an authoritative discussion of the subject.

In the introduction, it is stated that anemia, to produce symptoms in a moderately active individual, requires that the values for the concentration of the red cells or hemoglobin be reduced about one-half. When the blood loss is rapid, as from hemorrhage, a considerably smaller loss may produce serious signs. A gradual reduction may proceed to quite an extreme degree without symptoms, especially when the patient is resting in bed.

Pallor does not always denote anemia, as all have noted, but may be due, the authors state, to constriction of the peripheral vessels as in fainting, or increase of fluid in the tissues, as in myxedema or nephritis. Patients with lesser grades or even more marked anemia may not appear pale, because of dilatation of the peripheral vessels, the pink cheeked anemia, ("anemia rubra," Osler).

A comprehensive classification of the anemias is presented. Among the rarer types, the macrocytic anemia which may occur in pellagra is discussed, as is sometimes seen in individuals subject to chronic alcoholism or gastro-intestinal disorders, probably due to deficiency of vitamin B.

With regard to treatment, attention is called to the necessity of establishing a diagnosis before, and not after, the blood picture has been obscured by indiscriminate therapy. Transfusion is believed to be only rarely indicated in pernicious anemia because improvement will usually begin

about two days after parenteral therapy with liver extract is begun

The potency of parenterally administered liver extract is found to be at least sixty times that of the oral. For oral administration, combinations of liver and gastric tissue are said to be the most concentrated sources of active material

It is convenient to have this section of the Oxford Medicine separately bound

W. E. McCOLLOM

Minor Surgery By Frederick Christopher, M.D. Third edition, reset. Octavo of 1030 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$10.00

The present 1936 edition is the third since 1929 and is a much larger volume containing 1030 pages with 709 illustrations

The book has been brought up to date, and the author has been able to determine the dividing line between major and minor surgery

His presentation of the manner of treatment of injuries and minor surgical ailments involving any or all parts of the body, is complete and clearly illustrated, and is not to be found in many volumes on general surgery

The book is excellently adapted to meet the needs of the intern and the many physicians who for some years have been detached from surgical contacts

RALPH F. HARLOE

Parenteral Therapy A Ready Reference Manual of Extra-Oral Medication for Physicians, Dentists, Pharmacists, Chemists, Biologists, Nurses, Medical Students and Veterinarians. By Walter F. Dutton, M.D. and George B. Lake, M.D. Quarto of 386 pages, illustrated. Springfield, Charles C. Thomas, 1936. Cloth, \$7.50

The administration of medicaments by all methods except by the alimentary route is described in technical detail in this useful volume. The introduction, after a discussion of parenteral therapy in general, furnishes a list of the normal standards of the various blood chemical values. General technical methods are then described, especially the description, selection and care of various types of syringes and needles. The most desirable gage, length and type of needle for different procedures is shown in tabular form. The authors then go on to describe the proper procedures in intradermal, hypodermic, intramuscular and intravenous injections

Blood transfusion, artificial pneumothorax, intraspinal serum injections, cysternal and intraventricular puncture are described, also intravenous and infiltration anesthesia, caudal, epidural and spinal

anesthesia. The injection treatment of hernia, hydrocele, varicose veins and a chapter on ionic medication will also be found. The last half of the book includes a therapeutic index and pharmacologic notes

Many practitioners will find it a convenient volume to have.

W. E. McCOLLOM

Your Breath and Your Health. By Louis M. Pearlman, M.D. Octavo of 128 pages, illustrated. New York, Academy Publishing Company, 1936. Cloth, \$1.00

This work is divided into three parts. The first part is devoted to general consideration of the anatomy and physiology of the circulation and respiratory systems

The second part takes in the local causes of bad breath, stressing chiefly, foods, dental conditions, diseased tonsils and sinus disease and the part played by each in the production of bad breath

The third part is devoted to systemic causes of bad breath

This volume is intended for the education of the intelligent layman. The subject is treated simply yet thoroughly. The illustrations are instructive and clear. Some popular fallacies are dispelled and the information is easily assimilable, there being an ample glossary appended

SAMUEL ZWERLING

Urology in Women A Handbook of Urinary Diseases in the Female Sex. By E. Catherine Lewis, M.S. Second Edition. Octavo of 100 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth, \$2.25

This little handbook comprises one hundred pages covering urological lesions of the female urethra, bladder, ureter and kidney considered in this order. Venereal diseases are purposely omitted. The text is authoritative, concise and well-written and is fully illustrated. Only selected salient data in diagnosis and treatment are given. A limited number of references appear in each chapter

The author deserves special commendation for contributing such an excellent clinical compendium which should prove of interest and value to urologist, gynecologist and practitioner

AUGUSTUS HARRIS

Post-Graduate Surgery Edited by Rodney Maingot, F.R.C.S. Volume II. Quarto, illustrated. New York, D. Appleton-Century Company, 1936. Cloth, \$45.00 for set of three volumes

In Volume II of this work there are ten chapters devoted to surgery of head, spinal column and salivary glands, neck, breast, thorax, female genital organs, urinary sys-

tem and male genital organs, sympathetic nervous system, adrenal gland, injection therapy, and infections of the hand. There are 1134 figures in the text. The volume comprises 1825 pages, including a comprehensive index. As in the first volume, the various chapters have been written by surgeons particularly interested and experienced in the subject matter which they are presenting. The drawings, illustrations and plates add greatly to the clearness of the text. The latter is in general briefer than might be desired as regards the clinical and pathological aspects of the various conditions described but inasmuch as the volume in general has been written for the advanced surgeon rather than the student, the technical procedures, operative measures and mechanical therapeutic treatment are rather fully considered and fairly comprehensive. The volume is therefore more useful to the surgeon of experience, to acquaint him with the operative practices of his English colleagues and is interesting from this point of view. However, limited references are made to the surgical contributions of foreign countries and references in the text are extremely limited and the chapters are practically without bibliography. This is unfortunate particularly for anyone who would wish to know more fully the contributions of other than the English surgeons. Accordingly, the volume is not adapted to the more particular needs of the junior student in surgery. The volume is recommended to post-graduate surgeons in accordance with the points above mentioned.

EMIL GOETSCH

The Extra-Ocular Muscles. A Clinical Study of Normal and Abnormal Ocular Motility. By Luther C. Peter, M.D. Second edition. Octavo of 351 pages, illustrated. Philadelphia, Lea & Febiger, 1936. Cloth, \$4.50.

The teaching of ophthalmology has changed a great deal in the past few years and the approach to the specialty is more formal and left less to the individual to decide how he shall go about it. Post-graduate courses are given in several large cities extending over many months, and eye hospitals everywhere conduct courses on various subjects for their internes.

Improved technique in muscle surgery and more scientific study of binocular vision, "amblyopia exanopsia," suppression of images and orthoptic training has awakened a strong interest in this particular branch of ophthalmology.

For both the beginner and the practitioner Dr. Peter's book will be of interest and a great help. The reader is never carried too far into debatable territory and if there is a doubtful position beyond which we

cannot go at present, the attitude of the author is always conservative. It would seem that the publishers could not have selected a more opportune moment for its appearance.

RALPH LLOYD

Animal Micrology. Practical exercises in Zoological Micro-Technique. By Michael F. Guyer. Fourth Revised Edition. Octavo of 331 pages, illustrated. Chicago. The University of Chicago Press, 1936. Cloth, \$2.50.

Six years have elapsed since the last edition of this practical textbook, guide, and reference manual. A few minor additions and special techniques appear, and a new chapter explaining the dioxan method for histological preparations is a distinct contribution. It should popularize this technic in the United States, and certainly better elaborates the method than Shenan's recent text. This standard volume with its wealth of material is essential to all tissue laboratory workers.

IRVING M. DERBY

The Surgical Clinics of North America. Volume 16, number 1, February, 1936 (Chicago number). Published every other month by the W. B. Saunders Company, Philadelphia & London. Per Clinic Year (6 issues). Cloth, \$16.00, Paper, \$12.00.

The February issue of this publication illustrates the work at the Chicago Clinics. Part of the volume is devoted to a symposium on cancer of the cervix and is a very complete treatise on the subject.

An interesting article by Dr. Lewin deals with Manipulative Surgery and in its clear cut presentation clarifies a number of obscure points in this important and neglected chapter of orthopedics.

A large number of other stimulating articles make this issue an important one of the series.

GEORGE WEBB

To Raise These Hairs. By Fred Rothermell. Octavo of 350 pages. New York, Lee Furman, Inc., 1936. Cloth, \$2.50.

A country doctor comes to New York and has a hard, but soul satisfying time in general practice. His no good wife finally leaves him to his own resources and he muddles through fairly well until he is arrested and tried for inducing an abortion not for money but out of sympathy. The book is full of medical words, many of them queer like "exploded aneurysm, cranium forceps and septemia." The technique of abortion is described in detail. Much vulgar talk and strained realism like this description of a prenatal examination "Naked to the hips has abdomen a hard yellow hydro-cephaloid head with one eye and a beard of tangled red hair."

"Pure fiction"

CHARLES A. GORDON

Chemical Procedures for Clinical Laboratories By Marjorie R. Mattice, A B Octavo of 520 pages, illustrated Philadelphia, Lea & Febiger, 1936 Cloth, \$6 50

This is a well organized and clearly written text. The author very wisely includes in this volume of 520 pages not only the latest analytical methods, but also procedures for obtaining material. Internes should find this inclusion very valuable. A fair portion of the book is devoted to well described methods of preparation of reagents.

While the author has intended this volume to be a laboratory guide and not a reference book this reviewer feels that where she has cited an author as a reference, such a reference should be complete, as it is with some, and not cite merely the name and date. However, this is a minor criticism of a book that should prove to be an asset in any laboratory where biochemical assays are being attempted.

MORRIS L. RAKIETEN

Principles and Practice of Recreational Therapy for the Mentally Ill By John E. Davis, B A Octavo of 206 pages New York, A S Barnes & Company, 1936 Cloth, \$3 00

Workers for rehabilitation of mentally ill know the distinct importance of recreational therapy. Application of this knowledge has been hampered considerably by lack of any complete working formulary. The authors, from a large experience, have provided for that deficiency in this original work, the first to present in concise form definitely detailed information and procedures for therapists, and for the medical administrator. Theoretical material has been furnished for proper understanding of the practical matter, which is maximal throughout. Beyond direct therapeutic principles furnished, systems of organization and administration as well as a course of instruction for personnel have been indicated. It is a publication not only important for the student therapist and practicing technician but particularly useful to physicians treating institutionalized mental cases.

IRVING M. DERBY

The Relief of Pain. A Handbook of Modern Analgesia By Harold Balme, M D Octavo of 392 pages Philadelphia, P Blakiston's Son & Company 1936 Cloth, \$4 00

"It is a successful attempt to assemble and evaluate the factors determining the alleviation and prevention of physical pain" (From the Introduction by Farquhar Buzzard, Regius Prof Med Oxon) The

author's intent is to use pain in the discovery of the processes of disease, and to advertise the most efficacious remedies to combat it. General anesthesia is not included since its application is to the emergencies of acute pain. The book is a research into Analgesia.

It is a recent composition, a comprehensive study, and generously critical, it is well arranged as to fact and easily read as to form. Operations are not decried by any means, nor is general anesthesia belittled, neither are drugless methods overemphasized. If opium is, maybe, somewhat slighted in a surplusage of milder drugs, it is because the author's loadstar is the search for the best treatment adapted to the particular call for relief from the pain of a well diagnosed pathological process.

To a list of seventy-five analgesic drugs are added the trade name with the manufacturer, the composition, therapeutic use, and the dosage. "Those of the British Pharmacopeia are not given in detail as their composition and action are so well known." We find Aspirin, Cibalgin (Ciba), Combral (Bayer), Dilaudid (Knoll), Larocain (Roche), Luminal (Bayer), Vegamin (Warner), a dozen or more liniments. It would be interesting to have the list reviewed by the Council on Pharmacy and Chemistry. Not the least inviting chapters are those of part IV. The 29th dealing with Rest and Posture, the 30th—Baths and Packs, and the 31st—given in quite some detail to Movements, Massage and Electrical Treatment. The two latter are written by Matthew B Ray, D S O, M D, M R C P. Better read the book. It is suggestive, anyway. It could provoke profitable self-criticism.

A. F. ERDMANN

Lectures on Diseases of Children. By Robert Hutchison, M D. Seventh edition. Octavo of 452 pages, illustrated. Baltimore, William Wood & Company 1936 Cloth, \$6 75.

The scope of this volume consists of the complete series of clinical lectures given by Dr Hutchison as a systematic course at the London Hospital. These classical lectures are not intended as an exhaustive treatise on the diseases of childhood, but rather take the form of clear presentations of the author's rich experiences as a pioneer in his specialty. Many of his views are not modern, and the author does not expect the reader to consider them so. The student and experienced pediatrician may both benefit from reading Dr Hutchison's seasoned opinions and views, so clearly set forth in this book.

Chemical Procedures for Clinical Laboratories By Marjorie R. Mattice, A B Octavo of 520 pages, illustrated Philadelphia, Lea & Febiger, 1936 Cloth, \$6 50

This is a well organized and clearly written text. The author very wisely includes in this volume of 520 pages not only the latest analytical methods, but also procedures for obtaining material. Internes should find this inclusion very valuable. A fair portion of the book is devoted to well described methods of preparation of reagents.

While the author has intended this volume to be a laboratory guide and not a reference book this reviewer feels that where she has cited an author as a reference, such a reference should be complete, as it is with some, and not cite merely the name and date. However, this is a minor criticism of a book that should prove to be an asset in any laboratory where biochemical assays are being attempted.

MORRIS L RAKIETEN

Principles and Practice of Recreational Therapy for the Mentally Ill By John E Davis, B A Octavo of 206 pages New York, A. S. Barnes & Company, 1936 Cloth, \$3 00

Workers for rehabilitation of mentally ill know the distinct importance of recreational therapy. Application of this knowledge has been hampered considerably by lack of any complete working formulary. The authors, from a large experience, have provided for that deficiency in this original work, the first to present in concise form definitely detailed information and procedures for therapists, and for the medical administrator. Theoretical material has been furnished for proper understanding of the practical matter, which is maximal throughout. Beyond direct therapeutic principles furnished, systems of organization and administration as well as a course of instruction for personnel have been indicated. It is a publication not only important for the student therapist and practicing technician but particularly useful to physicians treating institutionalized mental cases.

IRVING M. DERBY

The Relief of Pain. A Handbook of Modern Analgesia By Harold Balme, M D Octavo of 392 pages Philadelphia, P. Blakiston's Son & Company 1936 Cloth, \$4 00

"It is a successful attempt to assemble and evaluate the factors determining the alleviation and prevention of physical pain" (From the Introduction by Farquhar Buzzard, Regius Prof. Med. Oxon.) The

author's intent is to use pain in the discovery of the processes of disease, and to advertise the most efficacious remedies to combat it. General anesthesia is not included since its application is to the emergencies of acute pain. The book is a research into Analgesia.

It is a recent composition, a comprehensive study, and generously critical, it is well arranged as to fact and easily read as to form. Operations are not decried by any means, nor is general anesthesia belittled, neither are drugless methods overemphasized. If opium is, maybe, somewhat slighted in a surplusage of milder drugs, it is because the author's loadstar is the search for the best treatment adapted to the particular call for relief from the pain of a well diagnosed pathological process.

To a list of seventy-five analgesic drugs are added the trade name with the manufacturer, the composition, therapeutic use, and the dosage. "Those of the British Pharmacopoeia are not given in detail as their composition and action are so well known." We find Aspirin, Cibalgm (Ciba), Compral (Bayer), Dilaudid (Knoll), Larocain (Roche), Luminal (Bayer), Vegamin (Warner), a dozen or more liniments. It would be interesting to have the list reviewed by the Council on Pharmacy and Chemistry. Not the least inviting chapters are those of part IV. The 29th dealing with Rest and Posture, the 30th—Baths and Packs, and the 31st—given in quite some detail to Movements, Massage and Electrical Treatment. The two latter are written by Matthew B. Ray, D S O, M D, M R C P. Better read the book. It is suggestive, anyway. It could provoke profitable self-criticism.

A. F. ERDMANN

Lectures on Diseases of Children. By Robert Hutchison, M D. Seventh edition Octavo of 452 pages, illustrated. Baltimore, William Wood & Company 1936 Cloth, \$6 75

The scope of this volume consists of the complete series of clinical lectures given by Dr. Hutchison as a systematic course at the London Hospital. These classical lectures are not intended as an exhaustive treatise on the diseases of childhood, but rather take the form of clear presentations of the author's rich experiences as a pioneer in his specialty. Many of his views are not modern, and the author does not expect the reader to consider them so. The student and experienced pediatrician may both benefit from reading Dr. Hutchison's seasoned opinions and views, so clearly set forth in this book.

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines its step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

LOCATED in the most beautiful section of the Ramapos Mountains, at an elevation of nine hundred and fifty feet in dry and exhilarating air, cool in summer and remarkably healthful at all seasons of the year

Comparable to a private estate of two hundred and fifty acres with woodlands, ornamental grounds, bridle paths, driveways, mountain paths, wooded ravines, rare trees and shrubbery, orchards, meadows, vegetable and flower gardens, golf, clock golf, croquet and tennis courts—providing the desired privacy with the utmost freedom for outdoor exercise and recreation

One of the most attractive of sanatoria, as well as one of the most efficient, being particularly equipped to care for a limited number of cases not violent, dangerous, noisy or otherwise objectionable, at greater economy than found generally and under the care of a most proficient medical and nursing staff

FALKIRK IN THE RAMAPOS
CENTRAL VALLEY • ORANGE COUNTY • NEW YORK

THEODORE W. NEUMANN, M.D.
Physician-in-Charge

YOU CAN ENJOY IT

THREE TIMES A DAY!

Tomato Juice—

WHAT KIND DO YOU USE?

Rich ripe tomatoes, carefully inspected, then gently pressed for their full-flavored juices? That's the way WEGNER'S is made. Preparation and packing in one of the most efficient factories in the country, according to modern scientific standards, insure utmost uniformity in vital food elements, and purity.

Carried by caterers of fancy groceries — if your dealer has none in stock, tell him to order from

WEGNER CANNING CORP., SODUS (Wayne Co.), N. Y.

A Guide to Select Schools

SCHOOLS OF REFINEMENT WITH HIGH RATING IN EDUCATIONAL AND CULTURAL ADVANTAGES

NORTHWEST INSTITUTE

Offering thorough course in clinical laboratory technique, including Basal Metabolism, in 9 months. Also X Ray and Physiotherapy in 3 months. Unusually high graduate placement.

WRITE FOR CATALOG.
3422 E. Lake St. MINNEAPOLIS, MINN.

A PROFESSION FOR
MEN AND WOMEN

LABORATORY AND X-RAY TECHNIQUE

Complete course including clinical laboratory technique and basal metabolism in eight months. X Ray course two months. Small classes with personal supervision. Student Dormitory maintained. Write for catalogue.

Eastern Academy of Laboratory Technique,
1707 Genesee St., Utica, N Y

Students' Activities

Half way between work and play, various activities of the students are purely voluntary, yet are important in training them esthetically or culturally or in preparing them in other important ways for later life. The boy or girl whose soul thrills to music has a source of pleasure that should be cultivated, and many schools have glee clubs, choirs, orchestras, and bands where the student can have no end of good times and yet receive the right training. There is nothing finer than fine music, and there is nothing much worse than bad music, and the parents of a student musically inclined will do well to look into this part of the school life.

Another student activity is the school paper or magazine. Many a successful writer has made the start on a school publication. For that matter, however, everyone, even in the most every-day business life, has more or less writing to do, and work on the student periodicals in school and college, gives ease, fluency, and facility in handling our sometimes rather balky language. The pleasure of being able to dash off a rattling good story or a humorous or serious bit of verse is also one of the joys that help make life worth while.

Debating has in it the fun of a good fight, and brings out the splendid qualities of fast,

vigorous thinking, quick repartee, ability to capture and hold an audience, and the rare capacity to take defeat with a smile. All these qualities are invaluable in any kind of career, and a school with well-trained debating teams is the place to develop them.

School athletics can be the making of a boy—or his ruin. He can learn to be a good sport on the playing field—or a poor sport. And what he learns there is very likely to color his whole life. We all remember the great President who said "Don't flinch. Don't foul. Hit the line hard!" There is a motto to carry us through good times and bad times, and it can be learned on the playing field better than anywhere else.

Parents sometimes give little thought to this vital side of school life. Yet it would be well worth their while to watch a few games of football, baseball and basketball, and see how the teams take a good licking. Do they put their backs into it like men when the game is going hard against them? That is the spirit they will need in later life, and the school field is the place to get it.

This is a side of school life that parents sometimes fail to consider, but it may turn out to be of prime importance. Don't overlook it.

Louden-Knickerbocker Hall

SPECIALIZING IN
NERVOUS MENTAL DISORDERS
NARCOTIC ADDICTION, ALCOHOLISM

Ideally located in a quiet residential section on the South Shore of Long Island, 8 3/4 miles from New York City.

Frequent musical entertainment, talking pictures, radio programs and dances provide diversion for patients. Completely staffed and equipped for all requisite medical and nursing care including Hydro and Occupational Therapy.

FOR PATIENTS WITH IRRITATION OF THE NOSE AND THROAT

IRRITATION from cigarette smoke can be a contributory factor in cases of congestion of the upper respiratory tract.

In such cases there are two courses that may be advised. Discontinuance of smoking. Or smoking Philip Morris, the only cigarette *proved** less irritating. Philip Morris & Company do not claim that Philip Morris Cigarettes cure irritation. But they do say that glycerine—a source of irritation in other cigarettes—is not used in the manufacture of Philip Morris.

What Every Woman Doesn't Know—How to Give Cod Liver Oil

Some authorities recommend that cod liver oil be given in the morning and at bedtime when the stomach is empty, while others prefer to give it after meals in order not to retard gastric secretion. If the mother will place the very young baby on her lap and hold the child's mouth open by gently pressing the cheeks together between her thumb and fingers while she administers the oil, all of it will be taken. The infant soon becomes accustomed to taking the oil without having its mouth held open. It is most important that the mother administer the oil in a matter of fact manner without apology or expression of sympathy.

If given cold cod liver oil has little taste, for the cold tends to paralyze momentarily the gustatory nerves. As any "taste" is largely a metallic one from the silver or silverplated spoon (particularly if the plating is worn) a glass spoon has an advantage.

On account of its higher potency in Vitamins A and D Mead's Cod Liver Oil Fortified With Percomorph Liver Oil may be given in one-third the ordinary cod liver oil dosage, and is particularly desirable in cases of fat intolerance.—*Adv*

Air Conditioning Comes to the Animal Laboratory

We are reminded almost daily that we are witnessing the beginning of a new era of increased comfort of living, better safeguarding of health and greater efficiency due to the adoption of air conditioning in homes, stores, offices, theatres and hospitals. But while it is easy to appreciate the benefits to human beings from the proper regulation of the temperature and humidity, and the removal of irritant gases from the air we breathe, only a trained laboratory worker immediately visualizes the advantages of maintaining laboratory animals in surroundings where the atmospheric conditions are regulated with as great care as in homes or hospitals.

The Lilly Research Laboratories have evidence gained from such care of experimental animals over a period of almost two years that not only is the number of guinea pigs, rats, rabbits, cockerels and other animals which ordinarily die because of the heat and other devitalizing effects of summer, reduced to a minimum but pharmacologic assays and research experiments yield much more dependable results. These observations are proof of an indirect benefit which we enjoy from air conditioning because, surely biologic assay is a cornerstone of modern medicine.—*Adv*

Lone Survivor Rescued by Steamer—but Saved by Chief Surgeon

Dr Kort Zinner, chief surgeon of the *SS Westernland*, told an amazing story of how the seventeen year old cabin boy, Fritz Roethke, sole survivor of the *Isis* was resuscitated.

Fritz Roethke was found in a lifeboat in an unconscious and utterly exhausted condition after having spent thirteen hours in an open lifeboat without food or water. Dr Zinner stated that the young boy had no pulse action and that he had inhaled a quantity of salt water and was on the point of death. Dr Zinner states that the salt water was pumped gradually from the boy's stomach and at the same time warm blankets and hot water bottles were applied together with heart stimulants. It was not until six hours after he was rescued that there were any signs of recovery and his temperature was then still subnormal. The physician never left the boy's side for twenty-four hours and was finally compelled to use an electric ray treatment.

When the *Westernland* reached Antwerp the boy was still too weak to tell his story but he was beginning to recover some of his strength by that time. Needless to say the lad's parents and many others have poured congratulations upon the Captain of the *Westernland*, Captain Kahlbetzer, the boatswain who went overboard after the boy and the doctor who saved his life. The *Isis*, a modern, motor-propelled freighter of 4,454 tons, built in 1922, sailed from Hamburg bound for Philadelphia and Gulf of Mexico ports. During the season's worst storms, an SOS was flashed three times from the little German freighter as she floundered in distress in mountainous seas off Land's End, England.

The *Westernland* arrived at the scene at dusk and all through the night while she plunged and rolled all but helpless, her searchlights fingered through the rain and spray. Late in the morning she picked up the one survivor, and

The three principals in the thrilling rescue of a lone survivor of the ill-fated Isis—(left to right) Boatswain Frantz Beyer who brought the victim aboard, Captain Kahlbetzer who supervised the rescue and Chief Surgeon Kort Zinner who saved the shipwreck's life.

finally had to abandon hope of finding any of the remaining thirty-nine members of the ill-fated crew.

The first call for aid picked up by a Dutch tug said that a hatch was stove in and her holds were filling rapidly. A little later a message stated that the fore-castle head was under water and that the crew was preparing to abandon ship.

A misleading article published earlier in the year in a newspaper concerning the transfer of an appendicitis-stricken sailor to another ship, tended to give an impression that Red Star liners carried no staff physicians. The transfer was made to a ship only sixteen hours from its home port, more favorable for the patient, as his own steamer was bound for New York.

From this recent rescue, it is plainly evident that Red Star liners not only carry a ship's doctor, but very capable ones besides as Dr Kort Zinner's able treatment of the rescued man has proven

United Air Lines Places Big Order for Engines

United Air Lines has purchased sixty-eight Pratt & Whitney Wasp 14-cylinder engines, the largest order ever placed for engines of 1,000 horsepower or more for commercial planes. It was announced recently by W. A. Patterson, United's president. The engines are now being installed in United's new \$3,000,000 fleet of twenty-eight twin-engined Douglas transports, including fourteen and twenty-one passenger planes, and sleepers, for its New York-Chicago-Pacific coast route. The order was placed after competitive engine tests in one of the new twelve-ton Douglasses.

These engines, the only twin-row powerplants in use on passenger land planes, are similar to those used on the trans-Pacific clippers and on high-powered military and naval aircraft, including the world record-breaking

FOR YOUR WINTER VACATION— In MIAMI BEACH It's THE FLEETWOOD

THE Fleetwood, one of the finest hotels in Miami Beach, opens December 21st for the winter season. To guests of other DeWitt Operated Hotels, DeWitt Operation is an assurance of the finest in food and hotel service. DeWitt Operated Hotels rank with the world's best in comfortable, well furnished rooms, courteous yet unobtrusive service and good food.

Only the finest of food, 'the cream of the markets,' is purchased and it is carefully prepared by competent chefs and faultlessly served, at reasonable prices.

Those who contemplate a visit to Miami Beach, either for a short stay or for the season have the personal assurance of Theo DeWitt that the Fleetwood will be the finest spot in Miami Beach this coming winter season. All rooms are outside rooms, with plenty of ventilation, overlooking beautiful Biscayne Bay, with the city of Miami in the distance, in one direction, and the Atlantic Ocean in the other.

The Fleetwood has every conceivable comfort and convenience. With ocean bathing warmed by the Gulf Stream, just off shore, a choice of seven fine golf courses, fishing, boating and other sports, both horse and dog racing, polo, tennis, etc., every desire of the guest for entertainment may be gratified.

Arrangements may be made at the desk for fishing and boating trips. For those who wish to avail themselves of ocean bathing, the Fleetwood maintains a private bus service between the hotel and ocean beach, operating on a thirty minute schedule, with no charge to the guest for this service.

There is a private dock for yachts and motor boats on the bay side of the hotel and there are ample parking facilities for automobiles.

The best people of America choose Miami Beach for the winter season and the most discriminating choose the Fleetwood as their home while there.

Other DeWitt Operated Hotels include

In CLEVELAND it's THE HOLLENDEN	In COLUMBUS it's THE NEIL HOUSE	In DAYTON it's THE BILTMORE	In AKRON it's THE MAYFLOWER
In TOLEDO it's THE NEW SECOR

3,400-mile non-stop flight with flying boats from the Canal Zone to San Francisco

United officials said the fourteen-cylinder type motor will make United's fleet the most powerful passenger land planes in this country. They are rated at 1,000 horsepower, with maximum available horsepower, 1,150 per engine. United's Douglasses will be the only commercial planes in this country equipped with fourteen-cylinder engines—the nearest approach of other engines being nine cylinders

Using only 62 per cent of available engine power, United's new Douglasses will cruise more than three miles a minute, and with a cruising range of 1,500 miles, will enable United to reduce its present coast-to-coast flying time. Reserve power of the two-row engines will enable the airliner to maintain full flight with only one of the two motors in operation. It can climb two miles with only one engine in use. With both engines operating, the fully-loaded plane can climb 1,000 feet per minute, and attain a ceiling of 24,300 feet.

The twin-row Wasp engines contain various exclusive design features. They produce approximately one horsepower for only one and one-quarter pounds of weight. They have patented automatic mixture control and constant speed three-blade propellers, United having been the first airline to equip its entire fleet with this device.

The CORAL ISLAND Club

sleeping cars for central, south and west coast Florida resorts

Boston Section The "Gulf Coast Limited" will have a New England section beginning from Boston at 8 30 A. M., December 10, 1936, which will carry through sleeping cars daily for Miami and east coast resorts, St Petersburg, Tampa, and Sarasota, and intermediate resorts in all central Florida. New England is thus given its first one-night-out train to all the principal resorts in Florida.

The "Gulf Coast Limited" provides fast and convenient service to and from Savannah and Nahunta, Ga., (for Sea Island and Brunswick). Dining cars and coaches carried on New York and Boston section. Library lounge car between New York and St. Petersburg. Daylight trip through Georgia and Florida.

"The Miami"—Restored December 10, 1936, from New York at 9 40 A. M. through to Palm Beach, Miami and other Florida East Coast resorts. Arrive West Palm Beach before noon and Miami 1 40 P. M. Lounge, bedroom, compartment, drawing room and section sleeping cars, dining cars, coaches. Connects at Miami with P & O steamer for Havana.

"The Tamiami"—Continued until last trip December 9 from New York, December 11 from Florida. Fast one-night-out train with sleeping cars for both coasts and central Florida and gives morning, mid-day or afternoon arrivals. Connects at Miami with P & O steamer for Havana and at Tampa with P & O steamer for Key West and Havana. Lounge and dining cars. Coaches. Leaves New York 10 30 A. M.

"Havana Special"—Continued in service, with close connecting service at Penna. Station New York, leaving Boston at 4 00 P. M. Connects at Tampa with P & O steamer for Key West and Havana, and at Miami with Pan-American Airway planes for Nassau, Havana, West Indies Central and South America, and with P & O steamer for Havana.

"Palmetto Limited"—Continued in service between New York, Washington and Wilmington N. C., Charleston, S. C., Augusta and Savannah Ga. Sleeping cars to all points. Dining car and coaches.

Mid-South Resorts. Sea Island, Brunswick, Ga., served by the "Florida Special," the "Gulf Coast Limited," "The Miami," and the "Havana Special" to Nahunta, Ga., Thomasville, Ga. via "Havana Special" to Savannah thence A. C. L. No. 57, or on above trains to Nahunta, Ga., thence private motor arrangements.

The Atlantic Coast Line has the co-operation of the New York, New Haven & Hartford R. R., the Pennsylvania Railroad, the Richmond, Fredericksburg & Potomac R. R., the Florida East Coast Railway and the Pullman Company in providing this fine train service.

Paris Exposition to Feature a Section on Medicine

A special section of the 1937 Paris Exposition will be devoted to medical demonstrations, discoveries and developments. The professors Gosset and Roussy, in charge of this division, state that emphasis will be placed on the scientific character of modern medical methods. There will be three large pavilions dedicated

to different branches of medicine and all will contain vivid evidence of their evolution. The Claude Bernard pavilion, for instance, will contain, among innumerable other interesting subjects, a transparent man, illuminated so as to show the principal glands. Every branch of medicine will be represented and whenever possible, demonstrated, whether actually or by motion pictures. In the Laennec pavilion, devoted to great clinical discoveries, will be shown old medical instruments, books and relics of the 19th century, as contrasted with those of to-day, and besides, this section of the Paris Exposition will give a remarkable insight as to what may be expected of medical science in the future.

The Chamberlin at Old Point Comfort Announces Improvements

At one of America's finest resorts, modernized facilities are being planned and rushed to make The Chamberlin Hotel the most all-around attractive spot for recreation and rest.

Work is under way on the water front Beach Club with outdoor salt water pool, European Cabanas, and such sports as paddle tennis, shuffleboard, and badminton. All rooms are being redecorated, the John Smith Coffee Shop is something newly completed, and the Jefferson Davis Dining Room will be one of the smartest in the South.

The Marine Roof is being renovated and new linens and china in keeping with the atmosphere of the Chamberlin, are being purchased. All rooms and suites will have new furniture and draperies. Meeting rooms for conventions will be air conditioned.

Bathing, both indoor and outdoor pools, boating, bicycling, croquet, dancing, fishing, golf, health studio, horseback riding, social activities, and sightseeing trips to historic places, are but a few of the many attractions that make this hotel popular.

Atlantic City for Christmas

"Evergreen by day, ablaze by night" is Atlantic City's Christmas slogan as the resort prepares for its greatest Yuletide display.

For years Atlantic City has been noted for its Festival of Light during the Christmas season and this year's display will be even more elaborate than heretofore.

The heart of the business district—Atlantic avenue from North Carolina to Michigan avenues—is a mass of red and green with ropes of lights crossing the avenue to form a color-

ful canopy above. Pine trees at the base of the street lights and twisted holly will go to carry out the Christmas motif.

The evergreens and electric light decorations along the Boardwalk will be augmented by the displays of the individual hotels. Here is an opportunity for the towering structures to present themselves in an even more colorful style and each tries to outdo the others in originality of their creations.

City parks at Albany and Arkansas avenues and Park Place will each have their huge Christmas trees and other appropriate decorations. The public buildings—the city hall, the railroad station and the high school—will also be fittingly illuminated.

Business houses and private homes, too, vie for honors in elegance of their displays. At the corner of Tennessee and Atlantic avenues, an igloo has been set up in a glade of evergreens and Santa Claus is on hand to welcome the little visitors.

Further down the island, Ventnor, Margate and Longport, residential suburbs of Atlantic City also decorate so that the entire section takes on a Yuletide atmosphere.

Thousands of visitors come from miles around to view the spectacular lighting effects and each night during the holiday period finds a steady stream of automobiles passing up and down the island. Most of the hotels take the guests on sight-seeing tours in their busses.

Special programs are also provided at this time of the year and pine logs burn in the open fireplaces while the guests join in singing Christmas carols. All of the hotels also stage parties for the youngsters with each tot receiving a stocking filled with gifts just as he or she would in their own homes.

Gay parties are planned for the hotel grilles and night clubs while the churches will have special services to care for the large number of persons from other cities who spend the holiday period at the shore.

The municipal convention hall becomes Atlantic City's sport center during the winter months. Ice hockey is on the card every Friday and Saturday night with the Atlantic City Sea Gulls playing leading amateur sixes from all sections of this country and Canada. Home games of the Sandspipers, the resort's representatives in the American Professional Basketball League, are played on Tuesday nights and wrestling is headlined every Monday.

For those who prefer to participate, there is ice skating on the convention hall rink every afternoon and evening, horseback riding on the beach, Boardwalk bicycling, golf on the nearby courses, and hunting on the mainland and meadows as long as the season continues.

Indian Summer All Winter

To those migrating South at this time of the year, Augusta, Georgia, and its environs offers ideal goal. For years it has been the favorite winter residence of the elite. Its remarkable climate is dry, warm and invigorating—not in the least enervating. Days of sunshine in which to enjoy popular outdoor sports or drives through beautiful and fascinating countryside—nights pleasantly cool for restful sleeping—all suggests a healthful atmosphere for both the well and the convalescent.

Here at Augusta is the Bon-Air, one of America's renowned winter resort hotels. All outside, modern rooms, well ventilated, and some with private verandah, a fireproof building throughout, and its exceptionally fine cuisine and service is ample recommendation for anyone going to Augusta for overnight or longer stays.

Free golf is featured for guests of a week or more, and here some of the country's great tournaments are held. In addition to golfing, there are excellent bridle paths, fresh-water fishing, tennis, archery, croquet, concerts, dinner dancing and numerous other things that entertain and provide pleasant vacations.

SNOWTIME IN THE MOUNTAINS WILL PUT SPRINGTIME IN YOUR HEART

LUCKY YOU planning a winter vacation even if it's just a winter week-end. Lucky because snow time has taken on new meanings of outdoor fun. The entire country went ski mad last year and now many Grossingerites know why we've been saying for over 20 years that the winter is the vacation time.

For the old bug a boo about freezing cold weather in the mountains is deadlier than last summer's golf-score. The mountain air is dry and therefore stingless. It actually seems warmer here than it does in the damp climate around New York. If you've never been to the mountains in the winter you have one of the biggest treats of your lifetime awaiting you. Ask any of your winter sports friends!

Christmas at Asbury Park

City officials and members of the Asbury Park Hotelmen's Association are making preparations for the active ushering in of the winter season here. A new high note in resort festivities is expected to be struck during the coming Christmas and New Year seasons with special programs arranged.

Special mid-winter dance programs have been arranged for the Casino while the Convention Hall will be the scene of free organ recitals twice daily.

Indoor swimming in the huge boardwalk salt water natatorium is enjoying a new vogue this season. Many of the hotel guests and parties of out-of-town visitors are enjoying the invigorating benefits of a daily dip in the tropical-ly heated pool.

Horseback riding through the newly laid out paths in the pine forests just west of the city is also finding increased favor.

Under the direction of Mayor Clarence E. F. Hetrick increased sundeck facilities have been established along the boardwalk. The glass enclosed and comfortably heated solarium are operated under municipal auspices and are attracting increased numbers of visitors daily who enjoy the combined benefits of the salt laden sea air and filtered sunshine. A series of winter pageants is being placed as one of the major attractions for the Christmas and New Year period.

Travel Brevities

DOCTOR Ramon Palacio Posse of Buenos Aires, returned home on the Grace Line's *Santa Clara*, after having made a study of Hospital organization in this country for the Argentine Government.

A GUEST of the St. George Hotel, Bermuda, Dr. Benjamin Press of New York, recently enjoyed a rest at this famous hostelry and island.

PASSENGERS sailing for Bermuda on the *Monarch of Bermuda* recently, included Dr. and Mrs. Samuel Grossman of Massachusetts.

RECENT GUESTS of the Hotel Lexington, New York City, included the following doctors: From New York—Dr. A. W. Bailey, Dr. J. L. Brockman, Dr. Paul Davis, Dr. W. J. Seesselberg, Dr. C. G. Glaser, Dr. H. L. Ungerer, Dr. Wm. Siegal, Dr. O. Knott, Dr. F. W. Bush, Dr. E. Danforth, Dr. J. P. Hagenauer and Dr. C. D. Miller. From New Jersey—Dr. S. P. Holland of the Jersey City Medical Center. From Connecticut—Dr. O. L. Beach, Dr. Theo. Lindstedt, and Dr. B. Dear. From Massachusetts—Dr. D. S. LeBeau and Dr. G. M. Mendelsohn. And from Pennsylvania—Dr. M. Buyer.

Christmas . . . 1936

*The Yule-log's in and set aglow
The candles flicker, while below
The pudding's passed, each makes a wish
And slowly stirs the lordly dish
The hamper then at waited sign
Is brought forth full of Christmas wine*

—Old English Song

Can there be any more acceptable gift than a hamper or basket of good sound wine?

CHAMPAGNE for the laughing, bubbling happiness

SHERRY for the warmth of hospitality and friendship

PORT for the completeness of a regal meal well enjoyed

If you are too busy to attend to your Christmas hampers or baskets let us have your list (we will call and discuss it personally if you like) and they will be carefully packed and delivered when desired
